Mr. Byng also discussed the question of education for administration both through such organizations as the Institute of Industrial Administration and within the ranks of industry itself. Finally, he urged that administration may justly claim to be a vital factor in industry and to offer an almost unlimited field of usefulness for the highest grades of intelligence. Our industrial future depends largely upon our methods of selecting and training administrators, and the general recognition of the high function they are called upon to perform.

New Ultracentrifuge Installation at the Lister Institute

On Tuesday, September 29, the Governing Body and the Director of the Lister Institute entertained Prof. The Svedberg of Uppsala and a number of interested physicists, biochemists and biologists on the occasion of the completion of the new ultracentrifuge plant. In welcoming the guests, Prof. J. C. G. Ledingham explained that in anticipation of Prof. Svedberg's visit to London on his way home from the Harvard celebrations, every effort had been made to put the finishing touches to the new installation. Dr. McFarlane, Lister Institute fellow in biophysics and a former pupil of Prof. Svedberg, had been almost entirely responsible not only for the design of the building to accommodate the new plant, but also for the supervision of the lay-out and assembly of all the accessory connexions, electrical, optical, refrigerating, etc., carried out by the Institute's engineering staff. Throughout the whole work, he had enjoyed the constant advice amd co-operation of Prof. Svedberg. The total cost of the installation, including the new building, was about £7,000, of which sum the Rockefeller Foundation had most generously contributed £3,400 in defrayment of the cost of the new machines.

The new laboratory is specially designed and equipped for investigations into the physical nature of very small particles, particularly protein molecules, but it is hoped also to extend its use to the study of the less well-defined entities such as viruses phages and antibody complexes.

The ground floor is largely taken up by two ultracentrifuges and their auxiliary machinery. Both machines, which were made in the workshops of the University of Uppsala to the design of Prof. Svedberg, have optical arrangements which make it possible to observe and photograph the contents of the rotating cell.

The smaller of the two machines is called the equilibrium centrifuge and is used for the determination of absolute particle size or weight. It runs at speeds up to 18,000 r.p.m. and usually for several days and nights continuously. The particles have then ceased moving, and a state of sedimentation equilibrium is set up, which allows of the calculation of absolute size from the final photograph.

The larger machine generates much greater centrifugal forces, up to half a million times gravity, and serves to throw down even the smaller protein molecules completely in a few hours. It is used to measure the sedimentation velocity constant of pure proteins and of the components of a mixture. In the case of native protein mixtures, such as blood serum, it is possible to centrifuge these without previous chemical treatment and to determine from the photographs the concentrations in which the component proteins are present.

The machine comprises a chrome nickel steel rotor of 7 in. diameter rotating inside a massive steel housing from which the air is evacuated and into which hydrogen is conducted at low pressure. The rotor is driven by high-pressure oil on the turbine principle, and the oil is also used to maintain the rotor at a constant low temperature. The usual speed is 60,000–70,000 r.p.m., and elaborate underground foundations are necessary to prevent the transmission of vibrations to the optical system. Owing to the position of the Lister Institute on a reclaimed bank of the Thames, it was necessary to drive piles to a depth of 40 ft. to support these foundations. The centrifuge is entirely controlled from an adjacent room in which temperature, speed, oil pressure, vacuum pressure, hydrogen pressure, etc., are measured and regulated with great accuracy. Photographs are taken every ten minutes through a window in the wall of the control room. Monochromatic light isolated from the mercury arc is used and the wave-length is chosen to suit the light absorption of the protein.

On the upper floor a roomy laboratory is provided for general chemical and physical investigations. A smaller room which is maintained at a constant temperature is intended for measurements of pH, conductivity, refractive index and cataphoresis constants. For measurements of the latter an optical system is set up, similar to those on the centrifuges, and this enables photographs to be taken of charged particles migrating in the electric field at a rate which is proportional to their charge. Two modernly-equipped dark rooms are provided, and in another room examination of plates is carried out and calculations made incidental to the various techniques in use.

The rooms in the new laboratory are supplied with compressed air, distilled water and refrigerated water, and are all electrically linked to a central distribution board from which they may receive various electrical supplies, including constant voltage D.C. of low and high voltage, and A.C. of variable frequency. Any room can communicate electrically with another through the main distribution board, and in this way remote electrical measurements may be taken rapidly without the need for transporting complicated apparatus.

Science News a Century Ago

Clarke's Magneto-Electric Machine

IN the *Philosophical Magazine* of October 1836 is a letter to the Editor from E. M. Clarke, of 9 Agar Street, West Strand, London, in which he describes his magneto-electric machine. The letter begins: "From the time Dr. Faraday first discovered magnetic electricity to the present, my attention as a philosophical instrument maker, has been entirely devoted to that important branch of science, more especially to the construction of an efficacious magnetic electric machine, which after much anxious thought, labour and expense I now submit to your notice".

Clarke's machine was designed primarily for physiological purposes. It had a permanent magnet of six laminations mounted vertically and an armature with soft iron cores wound with insulated wire, which could be revolved rapidly past the sides of the magnet poles. With what he called his "intensity" armature, which was wound with 1,500 yards of fine insulated copper wire, the effect, he said, produced "in the nervous and muscular system is such, that no person out of the hundreds who have tried it, could possibly endure the intense agony it is capable of producing; it is capable also of electrifying the most nervous person without giving him the least uneasiness". With his "quantity" armature, which was wound with fifty yards of thick copper bell wire, he could make the various experiments performed with a single pair of voltaic plates and could produce large and brilliant sparks by the light of which a person could read small print.

The Aurora Borealis of October 11, 1836

ACCORDING to *The Times*, shortly after 8 o'clock of the evening of October 11, 1836, "the Metropolis and its suburbs for miles around was thrown into a state of the greatest excitement by the northern hemisphere assuming a most awful fiery appearance, which seemed to indicate the existence of some dreadful conflagration in the north portion of the Metropolis. . . . Many of the fire engines were put into motion, and after scouring the northern parts of the City and suburbs in search of the supposed fire, it was at last discovered that the appearance of the sky had been caused by one of the most splendid of those remarkable phenomena known as the *Aurora Borealis*, or Northern Lights.

"From persons who had the opportunity of witnessing the magnificent spectacle from elevated situations, we understand there first appeared a large luminous arch, extending nearly from north to south, from which streamers appeared, very low. . . . Suddenly the whole hemisphere was covered with them, when the intensity of the light, the prodigious number and the volatility of the beams, the grand intermixture of all the prismatic colours in their utmost splendour, variegating the glowing canopy with the most luxuriant and enchanting scenery, afforded an awful, but at the same time the most pleasing and sublime spectacle in nature. . . ."

Braithwaite's Steam Floating Fire Engine

ONE of the most active mechanical engineers of a century ago was John Braithwaite (1797–1870), who with Ericsson constructed the locomotive *Novelty* which competed at Rainhill with the *Rocket*, and who with Vignoles laid out the Eastern Counties Railway. With Ericsson he constructed the first steam fire engine. In the *Mechanics' Magazine* of October 15, 1836, he described his "Steam Floating Fire Engine" for use on the River Thames. Though the superiority of the steam fire engine over hand-worked engines had been demonstrated at several fires in London, the London Fire-Engine Establishment, supported by various insurance companies, still clung to hand-worked engines.

The fire float of Braithwaite was a wrought iron boat 80 feet long, 13 feet wide drawing about 2 feet of water. It was fitted with a boiler "on Braithwaite and Ericsson's patent principle" and an engine of 30 horse power giving the craft a speed of about 9 knots. The engine could be coupled by gearing to either the paddle shaft or to double-acting pumps capable of discharging 4–5 tons of water per minute. In his communication to the *Mechanics' Magazine*, Braithwaite said that in spite of the various demonstrations he had given, the insurance companies declined to adopt his engine and "as things at present are I am minus about £3,500 by my invention".

Societies and Academies

Paris

Academy of Sciences, September 7 (*C.R.*, 203, 505–524).

Edouard Chatton and Félix Villeneuve: The sexuality and evolutive cycle of *Siedleckia* based on the study of *S. Caulleryi*, hologametogenous and blastogametogenous Sporozoa.

N. A. Slioskine: The rotation of a cavity filled with a viscous liquid.

Paul Muller: The Paris-Strasbourg gravimetric relation.

André Boutillier: Study of the dilatometric anomalies due to external forces in copper aluminium alloys containing 7–16 per cent of aluminium.

Henry Gault and Louis André Germann: 2-Methylene-1-butanol-3-one.

Raymond Furon: The existence of a Ural axis determining the structure of the Iranian Plateau.

Jacques Risler: The antiseptic power, either immediate or after prolonged action, of essential oils. The bactericidal power of essential oils can be prolonged by the addition of substances named 'abiotaxines'. Thus the addition of benzoin to oil of thyme prolongs the antiseptic action from 28 days to four years.

André Lwoff and Mme. Marguerite Lwoff: The nature of the factor V.

Henri Berrier: The influence of fasting in the tadpole of *Discoglossus pictus* on the proportion of substances acting as plant auxins.

September 14 (*C.R.*, 203, 525–548).

Edouard Chatton and Mlle. Simone Brachon: A protistan, parasite of the ciliate *Fabrea salina*: *Gregarella fabrearum* and its evolution.

Alexandre Ghika: The development in series of orthogonal functions, of analytical functions of two complex variables.

Marcel Mendes: The rotation of the heterogeneous ellipsoid studied by means of Lamé functions.

Douchan Avsec: The formation of convection vortices, in a gaseous layer, with thicknesses of the order of some centimetres.

J. Valensi and J. Sobieski: Tubes with mercury vapour at high pressure for illuminating smoke in aerodynamical studies. Description of a tube which can replace advantageously a carbon arc lamp in certain classes of photography.

Théodore V. Ionescu: The properties of an electron which rolls without slip and the radius of which varies inversely as the velocity.

Jules Farineau: The *K* spectrum and conductivity electrons of solid and liquid aluminium.

Horia Hulubei: Measurements of the *L* spectrum of radium (88).

Jean Cheymol: Verbenalol, aglucone and verbenaloside.

Boris Ephrussi, C. W. Clancy and G. W. Beadle: The influence of the lymph on the colour of the *vermilion* eye in *Drosophila melanogaster*.

Maurice Mathis: The diagnosis of yellow fever by intracerebral inoculation of the blood of the patient into white mice. Inoculation into *Macacus rhesus* has hitherto been the only certain test for yellow fever, but these animals are becoming more difficult to obtain. It is now shown that the macacus can be replaced by white mice.

Brussels

Royal Academy (*Bull. Classe Sci.*, 22, No. 7; 1936).

P. Stroobant: Observation of the eclipse of the sun on June 19, 1936, at the Astronomical Institute of the University of Brussels.

L. Godeaux: Cyclic involutions of the third order belonging to an algebraic surface.

F. Swarts: (1) Substitution of fluorine for other halogens with the aid of mercurous fluoride and the iodide (preparation of methyl fluoride). (2) Decomposition of cyclohexyl bromide in the presence of mercuric bromide and the formation of polymers of cyclohexene.

F. H. Van den Dungen: *A propos* of a theorem in statics due to M. Giovanni Lampariello.

J. Mariani: The principle of subjectivity and the theory of gravitation.

J. Jaumotte: Variation of the wind with altitude.

P. Gillis: A class of partial differential equations.

P. Bourgeois and J. F. Cox: The conditions of observation of the minor planet (1936 *CA*) = Adonis.

P. Burniat: Note on some canonical surfaces and on the surfaces of genus one.

M. Linsman: The singularities of the elementary curves in finite geometry (2).

B. Rosen and F. Bouffioux: Contributions to the study of the molecular spectra of the sulphur group.

E. Migeotte and E. Hoge: Observation of the eclipse of the sun on June 19, 1936, made with the equatorial of the Cointe Observatory.

Moscow

Academy of Sciences (*C.R.*, 2, No. 7, 1936).

K. Mardžanišvili: Simultaneous dissolution of whole numbers into *m*-th and *n*-th potentials.

L. Sretenskij: Determination of resistance to rolling of a vessel moving on the surface of water of finite depth.

G. Čelincev: Organic derivatives of potassium and their role in organic synthesis.

D. Mirlis and D. Deribas: Synthesis of tanning substances from carbohydrates.

V. Derwies: Genesis of the magnetite deposits of the Gora-Blagodat in the northern Urals.

B. Astaurov: New data on artificial parthenogenesis in the silkworm (*Bombyx mori* L.). Individual capacity for parthenogenesis is a hereditary character, probably due to a small number of genes having specific action.

B. Isačenko: Corrosion of concrete. There is some evidence of microbiological action on submerged concrete due to fungi (*Oospora Candida* and *Sporotrichum*).

A. A. Richter: An absorber of carbon dioxide for currents of atmospheric air.

V. Katunskij: Movement of growth-promoting substance and the growth of plants in an electric field. (Contribution to the study of electro-cultivation of plants.) A negative potential inhibits the movement of growth-promoting substance in the basipetal direction, while a positive potential stimulates that movement.

N. Konstantinov: The vernalization of tree-cotton.

T. S. Rass: Types of fish-eggs and their bearing on the classification of fishes.

(*C.R.*, 2, No. 8, 1936).

A. P. Dietzmann and S. A. Cunikhin : Classes and centre of a finite group.

S. Nikolskij : Linear equations in metrical space.

P. A. Walter : A current through a hydraulic grid with rounded lobes of small curvature.

A. P. Ilyina : Stratigraphy and fauna of the tertiary sediments of the western coast of Kamchatka.

W. A. Engelhardt and M. N. Ljubimova : The double mechanism of adenosine triphosphate stabilization in cells. (1) Reticulocytes.

W. A. Engelhardt and A. A. Bajev : The double mechanism of adenosine triphosphate stabilization in cells. (2) Nucleated avian erythrocytes.

A. I. Grečušnikov : Toxins of rust (*Puccinia*). The active principle of the toxin consists of two simple compounds, namely, ammonia and urea.

I. A. Stefanovskij : Influence of environmental factors on immunity of wheat. Retardation of sowing date increases the incidence of brown-rust.

V. V. Popov : The potential ability of various cells for lens development.

I. A. Rubtzov : A new Simuliid species (*Simulium oligocenicum*, sp.n.) from amber.

(*C.R.*, 2, No. 9, 1936).

I. Vinogradov : New results concerning the distribution of fractional parts of a polynomial.

L. V. Kantorovič : The elements of the theory of functions of a real variable with values belonging to a semi-ordered linear space.

V. Gavrilenko : Distribution of communicated velocities in turbulent uniform currents of liquid.

N. T. Fedorov and V. I. Fedorova : The problem of the curve of the spectral sensitivity of the eye.

V. Rasumovskij : Polarity and tautomerism.

N. I. Kobosev, B. V. Jerufejev and V. M. Savina : Hydration of aluminium nitride by active hydrogen.

A. E. Fersman : Application of *VEK*'s in geochemistry.

V. A. Novikov : The influence of the intensity of illumination on the development of the cotton plant. Cotton possesses a very wide range of physiological plasticity as regards intensity of illumination.

A. Machotin : Reduction phenomena in the morphology of the adult moth *Operophthera brumata* L. Loss of wings in the female leads to a greater development of the musculature of extremities. Reduction of digestive tract in the male is accompanied by the transformation of the stomach into an aerostatic apparatus.

J. Iežikov : Some considerations on the types of development of Metazoa from the egg.

Vienna

Academy of Sciences, July 2.

Max Pestemer, Trude Langer and Friedrich Manchen : Influence of substituted radicals on the ultra-violet absorption of benzene chromophores, both simple and conjugated with double bonds.

K. W. F. Kohlrausch : Studies of the Raman effect (58). Raman spectrum of organic substances (nitrogenous substances : (1), simple amines).

L. Kahovec and K. W. F. Kohlrausch : Studies of the Raman effect (59). Raman spectrum of organic substances (nitrogenous substances : (2), amino- and oxyacetic acid and its esters).

Otto Redlich and Walter Stricks : Raman spectra and vibrations of di- and tetradeuterobenzene.

L. Kuchler and F. Patat : Photochemical conversion of *o*-nitrobenzaldehyde to *o*-nitrobenzoic acid.

Gabriele Rogenhofer : Action of growth-promoting substances on bark formation in woody shoots.

L. Portheim : Action of β-indolylacetic acid on plants (1).

Kurt Lohwag : (1) A useful method of macerating wood tissues. (2) Preservation of the colours of the ordinary wood reaction.

Josef Kisser and Yoshio Kondo : Microchemical test of divalent and trivalent phenols by means of spot reactions.

Josef Mattauch : Measurements with a new type of mass-spectrograph.

Elisabeth Rona and Elisabeth Neuninger : (1) Artificial radioactivity of thorium. An actinium isotope of 42 hours half-period is formed on bombarding thorium with neutrons. (2) Artificial radioactivity of thulium. $^{170}_{69}\mathrm{Tm}$, formed by bombarding thulium with slow neutrons, has a half-period of $4 \pm \frac{1}{2}$ months.

Stefanie Zila : Development of a photographic method for the study of proton beams. Methods of sensitizing plates for the registration of protons are described.

Ernst Schäfler : Effect of γ-rays on desensitized photographic plates.

Kasimir Graff : Observation of the total solar eclipse of June 19, 1936.

Robert Willheim : The Pasteur-Meyerhof reaction in cancer glycolysis.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, October 12

University College, London, W.C.1, at 5.0.—Dr. R. J. Lythgoe : "The Physiology of Vision" (succeeding lectures on October 19, 26, November 2, 9).*

Tuesday, October 13

Society for the Study of Inebriety and Drug Addiction (at the Friends' House, Euston Road) at 4.—Prof. D. K. Henderson : "Alcoholism and Psychiatry" (Norman Kerr Lecture).

University College, London, W.C.1, at 5.—Dr. C. Reid : "The Endocrine Organs in relation to Metabolism" (succeeding lectures on October 20, 27, November 3).*

Illuminating Engineering Society (at the Lighting Service Bureau, 2 Savoy Hill, W.C. 2), at 5.30.—A. Cunnington : Presidential Address.

Thursday, October 15

Institute of Fuel (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W.1).

At 2.30.—Sir Philip Dawson : Presidential Address.

At 3.30.—Prof. Franz Fischer : "Production of Synthetic Motor Spirit" (Melchett Lecture).

King's College, London, W.C.1, at 5.30.—Dr. S. J. Davies : "Injection and Combustion in Oil Engines" (succeeding lectures on October 15, 22, 29, November 5, 12, 19).*

British Institute of Radiology, at 8.—Prof. J. A. Crowther : "Physics and Radiology" (Presidential Address).

National Smoke Abatement Society, October 14–17. Annual Conference to be held in the Science Museum, South Kensington, London, S.W.7.

Society of Chemical Industry (at University College, London, W.C.1), October 15–16. Conference on Automatic Control in Industry.

The British School of Archæology at Athens

FOR a month—from October 14 until November 14—the British School of Archæology at Athens is marking the completion of its fiftieth year of existence by holding an exhibition illustrating its activities and achievement at the Royal Academy of Arts, Burlington House, London, W.1, which is also made the occasion of an appeal for funds to maintain the efficiency of the School. For the archæologist who lightly passes from one millennium to another in his exploration of the ages before our era, fifty years is but a brief span. Nevertheless, the fifty years of "the British School", as it is affectionately known to its intimates, relatively few though they may be, are not far from covering the whole period which has seen the development of archæological excavation on ancient sites as a scientific method of reconstructing the cultural history of the great civilizations of the past, of which, for the most part, all other record, if such there were, has vanished.

"Gone are the walls that were so good,
And corn now grows where once Troy stood."

Though this no longer will be true, thanks to the co-operation of the Turkish authorities in the work of archæologists from the United States at Hissarlik, it was only an inspired faith in the works of Homer that led Schliemann first to excavate there in 1866, and eleven years later to dig at Mycenæ on the mainland of Greece, thus initiating those explorations on the sites of long-forgotten and deserted cities, palaces and temples, which not merely have transformed previous conceptions of the pre-historic past in classical lands, but also have built them up anew.

Schliemann, however great his merits as a pioneer, was too intent on the more spectacular aspects of the results of his excavations to elaborate a technique that could be termed truly scientific. By his excavations at Troy, Tiryns, and more especially at Mycenæ, he established the existence of a great civilization of the bronze age. Yet notwithstanding the development in the methods of excavation which followed, especially under the influence of Dorpfeld, it was not until the work of the British School at Melos, and more especially on the site of Phylakopi, in the years 1895–99, that a stratified site in Greece proper was excavated on scientific lines.

The enthusiasm aroused in the world of scholarship by the discoveries of Schliemann and others led to the foundation of the British School at Athens in the autumn of 1886, following on an article written by Richard C. Jebb. His proposal that such a school should be instituted aroused the active interest of the Prince of Wales, afterwards King Edward VII, and among its most active supporters were Prof. Percy Gardner, J. E. Sandys, Sir Frederick Leighton, D. B. Monro (later Provost of Oriel) and James Gow, as well as Francis C. Penrose, who became the first director, George A. Macmillan, honorary secretary from 1886 until 1897 and chairman of the Committee of Management from 1903 until 1934, and Walter H. Leaf, treasurer from 1886 until 1906. To the generous devotion and benefactions of the two last named the School is indebted more than to any for its survival in days of stress.

The objects with which the British School was founded were sufficiently wide. It was intended to afford British students of the literature, art, architecture, archæology and history of Greece of all periods from the earliest times to Byzantine and modern days, adequate facilities for travel and research in Greece itself. How varied have been the interests for which it has provided may be gauged by the names of only a very few of its students, such as Ernest A. Gardner, archæologist, David G. Hogarth, archæologist and geographer, Marcus N. Todd, epigraphist, Montague R. James, whose recent death is deplored, R. Schultz Weir, Byzantine archæologist, John L. Myres, archæologist, geographer and historian, now chairman of the Committee of Management, Sir James Frazer, author of the monumental edition of Pausanias, and Sir Arthur Evans, the School's most distinguished and senior honorary student.

Of the academic side of the student's life at the School little is known to the outside world, nor indeed of the intense application, incidental to archæological study. Yet those who care to turn over the pages of the thirty-four volumes of the "Annual" of the School will be astounded at the range of exploratory work—topographical, linguistic and cultural—there recorded, and representing only part of the mass of information collected by the students in the extensive journeys they have been encouraged to make in Greece, the islands and Asia Minor in the course of their term of residence. Indeed it is no exaggeration to say that our campaign in the Eastern Mediterranean and the Balkans in the Great War ultimately came to a fortunate issue largely through the knowledge of local conditions and of the language, customs and mentality of the peoples, which was possessed by members of the School serving in the Forces.

It is an interesting and fascinating occupation for the visitor to the School's exhibition to follow catalogue in hand the excavations there illustrated, which have been conducted by its members, in their chronological succession and to mark how, with the development of scientific method—a development in which the School has taken no small part—the work gains in intensity, the results in breadth of application. Unfortunately, this development cannot be followed here in detail, though a word must be spared for one piece of early research shown, which stands outside the better known activities of the School. This is the Byzantine work of T. S. Weir in the early 'nineties, which was before its time.

Although the work of the School in prehistoric archæology may be not unknown to the public in general outline, it becomes impressive in detail with even a mere recapitulation of the names of some of the sites which have been excavated. Beginning with Phylakopi, and ignoring familiar names which went before, we have Minoan Palækastro in Crete, Sparta with its temple of Artemis Orthia, the epoch-making Mycenæ, sites in Thessaly, Macedonia, Lesbos—this last excavation which under Miss Winifred Lamb has recreated the background of Troy—and the important early Hellenic sanctuary of Perachora, near Corinth, upon which the School is still engaged.

Although comment upon the results which have been achieved by these excavations is not possible, a moment must be spared for a more general reflection on the influence of the School on archæological method. As already mentioned, Schliemann in his excavations achieved his object of establishing the existence of a great bronze age civilization, although as regards substantiating the works of Homer he raised more difficulties than he solved. Later work of other excavators aimed primarily at elucidating, with such scientific precision as was envisaged from time to time, the more or less complete history of the site upon which they were engaged. But even in early days, in the work of the School there may be discerned the first steps towards the ideal of the modern archæologist, the reconstruction of a complete culture complex and its contacts, such as that by which is now being built up gradually, for example, the cultural reconstruction as an integrated whole of pre- and protohistoric times from the Eastern Mediterranean to India and eastern Asia. The pioneers in this movement—speaking now only of members of the School—were Arthur Evans and J. L. Myres, the latter of whom as a young student in 1893 was the first British explorer of Crete, and whose identification of the Kamares ware, previously found by Flinders Petrie in Egypt, first demonstrated connexion between Egypt and the Greek world at a date earlier than the Eighteenth Dynasty. The full flower of this pioneer work is to be seen in the truly remarkable collection now at Burlington House illustrating Minoan culture from its earliest to its latest phase, and demonstrating its external relations with Egypt and the East, which has been staged by Sir Arthur Evans. It forms the *clou* of the exhibition. It illustrates an advanced but early culture in a manner such as has never been seen before, and probably will never be seen again.

Since the School at Athens was founded, similar British Schools have been established elsewhere. To them we could wish no better fortune than that when they complete their fiftieth year, the tale of their success may be as great as that of their prototype.

Plant Pathology in the Tropics

Diseases and Pests of the Rubber Tree
By Arnold Sharples. Pp. xvii+480+4 plates. (London: Macmillan and Co., Ltd., 1936.) 25*s*. net.

THIS is a most notable addition to books on the diseases of tropical crop plants. Since Petch's "The Diseases and Pests of the Rubber Tree" (1921) and Steinmann's "Diseases and Pests of *Hevea brasiliensis*" (1925) were published, there has been great activity in investigating, in a more detailed manner than was formerly possible, the major diseases to which the rubber tree in the Eastern plantations is prone. Nowhere has this activity been more pronounced or more productive of striking results than at the Rubber Research Institute of Malaya, to which the author of the present book was seconded as head of the Pathological Division in 1931, after being Government mycologist in the Department of Agriculture for many years.

The establishment of the rubber plantation industry, through the foresight of a former Director of the Royal Botanic Gardens, Kew, is one of the romances of commerce. At the present time, some millions of acres of land, formerly mostly under high forest, are devoted to the cultivation of *Hevea brasiliensis* in Malaya, Ceylon, the Dutch East Indies and other countries of south-eastern Asia. For example, in travelling by train from Penang to Singapore, one passes through an almost continuous rubber forest which stretches away for miles on either side of the railway track. Such large areas devoted to the cultivation of a single crop, under humidity and temperature conditions particularly favourable to the development of parasitic fungi, may seem to offer a terrifying prospect for the establishment of epidemic disease. Happily, the rubber plantation industry has never been seriously threatened in this way, and this has been largely due to the skill and foresight of the plant pathologists who have served the industry so well.

It is sometimes stated that disease in a crop plant is merely a symptom that cultivation is being carried on under unsuitable conditions. However true this may be with regard to certain crops, no one who has had experience of rubber cultivation can doubt that the incidence of disease is a serious factor even in trees which are growing with the maximum vigour. Again, it is sometimes claimed, and rightly so in some instances, that the menace of disease can be overcome by the utilization of disease-resistant varieties; unfortunately, there seems to be no prospect of amelioration along these lines as regards *Hevea brasiliensis*. So far, no strains of the rubber tree have been discovered which have the desirable properties of resistance to disease; furthermore, most of the fungi which attack this tree are not highly specialized parasites such as those against which the plant breeders have achieved certain notable successes. The price of security is unceasing vigilance, and as regards the rubber plantation industry, plant pathologists will have to continue to exercise this watchfulness without remission.

General considerations of this kind are emphasized in Mr. Sharples' book, which in fact can be looked upon as a general treatise on the principles of plant pathology with particular reference to rubber cultivation. For this reason the book will have a wide appeal to plant pathologists in general as well as to rubber planters, for whom in some respects the book has been primarily written. No better book could be placed in the hands of a young plant pathologist proceeding overseas for his first period of service in a tropical country.

The immense importance of environmental factors in determining the incidence of certain parasitic diseases is rightly stressed. For example, the author points out that pink disease, caused by *Corticium salmonicolor*, occurs seriously in Malaya only in the regions of highest rainfall and in the vicinity of large forest reserves. *Oidium Heveæ*, the powdery mildew of the rubber tree and a comparatively recent arrival in the plantations, only attacks under certain weather conditions the new foliage which develops after the 'wintering' or annual defoliation of the trees. *Ceratostomella fimbriata*, causing Mouldy rot of the tapped bark, becomes a menace only under extremely high atmospheric humidity. In connexion with this disease, the author sounds a note of warning in regard to the danger of encouraging dense semi-arborescent growths of other species among the rubber trees (following so-called forestry methods of rubber cultivation) because of the excessive humidity which they occasion.

One of the most interesting sections of the book is that dealing with the root diseases of the rubber tree, which in some ways are the most difficult to combat. Most of the rubber plantations have been established on land previously under high forest. After felling the trees, root parasites such as *Fomes* *lignosus* and *Ganoderma pseudoferreum*, which were kept under control in the natural forest, develop actively and become a menace to the newly established plantation. Thanks to investigations carried out recently, chiefly at the Rubber Research Institute of Malaya, much new light has been thrown on the biology of these root parasites, with the result that more rational methods of control can now be carried out than hitherto. With the replacement of worn-out stands of rubber by superior high-yielding strains of trees, the control of these root parasites has become all the more imperative.

Among other topics dealt with in this book are the damage to trees caused by lightning—a subject to which little attention has hitherto been paid in the tropics—the insect pests of rubber trees—fortunately not a formidable list—and the methods of cultivation now in vogue in rubber plantations. An appendix contains a list of fungi recorded on rubber trees in Malaya, most of which are saprophytes. The book is profusely illustrated and admirably printed.

All who take an interest in the cultivation of tropical crop plants will appreciate the value of this book, and the rubber plantation industry in particular should be under a deep debt of gratitude to the author for his enlightening and comprehensive survey of many of the major problems which concern their estates. The publication of Mr. Sharples' book is high testimony to the services of the scientific experts without whose aid this romantic industry could never have been established.

F. T. BROOKS.

Blood Pigments

Essai sur la biochimie générale et comparée des pigments respiratoires

Par Prof. Jean Roche. Pp. 170. (Paris : Masson et Cie., n.d.) 40 francs.

PROF. ROCHE'S monograph is the first book the reviewer has met which deals at length with the comparative properties of the four principal groups of blood pigments, the hæmoglobins, the hæmocyanins, the chlorocruorins and the hæmerythrins ; it fills a much-felt gap. The author has limited himself to those aspects of the subject on which he has been personally engaged, thereby excluding any extended treatment of that common property to which they owe their name, their oxygen-binding ability, so that the outstanding physiological function of these fundamentally important pigments receives only occasional incidental reference. This is a deliberate omission, which may have been wisely made, but which many of Prof. Roche's readers will regret.

The work contains a great mass of very useful material ; it is essentially a review of the author's own researches, supplemented by a fairly complete summary of the literature on these topics, which includes the elemental and amino acid compositions of the blood pigments, their ultra-violet absorption spectra, their isoelectric points, acid-base titration curves, and their molecular weights. As a reference work, however, the book would have been much improved if an index had been provided (an almost inexcusable omission in a book of this character), if each topic had been treated coherently instead of being broken up into subdivisions entitled "previous work" and "personal research", if the bibliography (itself excellent) had been provided with some key to the references in the text, and if the proof-reading had been a little less casual (to cite a single example, the table on p. 35 contains fourteen references of which three are incorrectly ascribed ; there are also at least two significant omissions).

The main theme of the book is the specificity of the blood pigments, the differences not only between the four main groups, but also between different species in the same group, and sometimes even between different individuals of the same species, and Prof. Roche provides enough evidence to convince even the most sceptical that blood pigments possess scarcely any properties which fail to display such differences, given sufficient accuracy of measurement. The correlation of these varying properties with the needs of the organism has scarcely been attempted up to the present ; the problem is one which will rightly challenge comparative biochemists and physiologists in the future.

The outstanding virtue of this very useful book is the author's first-hand experience with the substances about which he writes, for he has personally undertaken extensive and valuable experimental work on each branch covered. He is enabled thereby to speak with an authority and assurance which goes far to compensate for the exclusion from his survey of fields which still cry for adequate comparative treatment.

Medical Biography

(5) The Proceedings of the Charaka Club
Vol. 8. (Published for the Charaka Club.) Pp. xvi +202 +31 plates. (New York: Columbia University Press; London: Oxford University Press, 1935.) 25*s*. net.

(1) SIR WILLIAM HALE-WHITE is to be congratulated on having employed his leisure on retirement from practice by the compilation in an intimate and attractive style of the life and work of seventeen eminent British physicians and surgeons of the nineteenth century, with some of whom he was personally acquainted.

General medicine is represented by Richard Bright, William Stokes, Thomas Addison, Sir William Gull and Sir Samuel Wilks; surgery by Sir Astley Cooper, Sir James Paget and Lord Lister; neurology by Sir Charles Bell, Marshall Hale and Hughlings Jackson; tropical medicine by Sir Patrick Manson and Sir Ronald Ross; public health by Edward Jenner and Sir John Simon; ophthalmology by Sir William Bowman; and anæsthetics by Sir James Young Simpson.

An added interest is given to the work by the remarkable versatility of several of these doctors. Richard Bright, for example, who is described as better known than any physician since William Harvey, was also a geologist and traveller, linguist and writer. Sir Charles Bell, in addition to being an eminent anatomist and surgeon and a pioneer in neurology, was also a skilful artist. Sir John Simon was alike eminent as a surgeon, pathologist and sanitarian, having been at different times president of the Royal College of Surgeons and principal medical officer of the Local Government Board, as well as author of a classical work on English sanitary institutions and a text-book on general pathology. Sir Ronald Ross, whose discovery of the mosquito as the transmitter of malaria is known to all, was also a poet, mathematician, novelist, water colour painter and musician. Sir John Young Simpson, who introduced chloroform anæsthesia, was president of the Society of Antiquaries of Scotland and member of several other archæological societies. With the exception of Addison, one of the ablest clinicians of his time, whose name is attached to pernicious anæmia and disease of the suprarenals, and Sir James Young Simpson, all were fellows of the Royal Society.

Short sketches of the lives of distinguished contemporaries of the principal characters are included, such as Robert Graves, author of the famous "Clinical Lectures", William Farr and Southwood Smith, the sanitarians, Henry Hill Hickman, a pioneer on nitrous oxide anæsthesia, and Thomas Hodgkin and Hilton Fagge, well-known physicians and contemporaries of Addison and Sir William Gull respectively.

(2) In his work on Benjamin Rush, Dr. Nathan G. Goodman gives a richly documented account of a man who was equally illustrious as a physician, humanitarian and patriot. His activities as an American patriot consisted in being the only doctor of medicine who signed the Declaration of Independence and in serving as Physician-General to the Middle Department of the Army. He has left classical descriptions of the relation of disease of the teeth to joint infection, cholera infantum, dengue and the hygiene of troops as well as a remarkable account of the yellow fever epidemic at Philadelphia in 1793.

By the introduction at the Pennsylvania Hospital of humane and judicious treatment of the insane, for whom he provided bathing facilities and occupational therapy, and by a careful study of the causes, symptoms and treatment of insanity in his essay on diseases of the mind, Benjamin Rush deserves the title given him by Dr. Goodman of "the first American psychiatrist". His humanitarianism was also shown by his denunciation of slavery and its attendant evils, his protest against capital punishment, his interest in prison welfare and his campaign against alcoholism. Lastly, as educator, Rush was the foremost teacher of medicine in America in his time and took an active part in the foundation of Dickinson College at Carlisle, Pennsylvania.

In addition to brief notes on the text, a bibliography of twenty-seven pages including manuscript sources, a list of Rush's published works, contemporary newspapers and secondary works is appended. The text is interspersed, among other illustrations, with portraits of Rush and his wife, pictures of his birthplace and last residence and of the Pennsylvania hospital to which he was attached.

(3) In her sympathetic study of Franklin Paine Mall, professor of anatomy at Johns Hopkins University, his former student, Miss Florence Rena Sabin, relates the life and work of a man who, like Osler, Welch, Flexner and Halstead, transplanted to the United States modern scientific medicine from Europe, where Mall was the pupil of His in anatomy and embryology and of Karl Ludwig in physiology. Before the return of this small but influential band of men from Germany in the 'eighties, the United States possessed no laboratories, no equipment and no money for education, but within a decade these deficiencies were made good. In addition to the active part which he played in the organization of scientific societies such as the Association of Morphologists and the American Anatomical Association, Mall was responsible for the appearance in 1901–2 of the *American Journal of Anatomy*, of which he edited the first seven volumes, as well as the first volume of the *Anatomical Record.*

Though primarily an anatomist who founded a school of anatomy in the United States and trained men who carried his teaching to other laboratories, Mall had also a profound influence on medical education in general. Miss Sabin quotes in full the appreciation of his work which appeared in NATURE, 96, 205 (1916); 106, 179 (1920). A bibliography of his most important publications is appended, as well as the German text of letters received from His and Ludwig, with whom Mall corresponded for many years after leaving Germany.

(4) In the autobiography entitled "Those Were Good Days", Carl Ludwig Schleich, the versatile and eccentric surgeon who died in 1922, gives a vivid account of his childhood, student life and tempestuous maturity, together with a living picture of pre-War Germany. After acting as assistant to a number of distinguished chiefs, including Langenbeck and Bergmann, the surgeons, and Virchow, the pathologist, to each of whom a chapter is devoted, as well as to Senator, the physician, and Olshausen, the gynæcologist, he founded a private clinic for surgery and gynæcology, where he initiated the method of regional anæsthesia for which he is best known. The method at first met with a hostile reception, but ten years later Miculicz, a leading German surgeon, announced that he had performed thousands of completely painless operations by this means. A special chapter is devoted to Ehrlich, as man and scientific worker, whom Schleich used to visit frequently in his Biological Institute at Frankfort.

Schleich's activities were not confined to his profession. He was an intimate friend of August Strindberg, the novelist and playwright, and of Richard Dehmel, the poet, and was himself the author of numerous poems and plays, a musician and painter. An epilogue by his friend Wolfgang Goetz is appended to the autobiography.

(5) The eighth volume of the *Proceedings of the Charaka Club* (a select band of New York practitioners interested in the history of medicine) contains several papers on medical biography. The first of these is a sketch by Dr. Archibald Mallock of the life of James de Berty Trudeau, artist, soldier and physician, and father of the better known Edward Livingston Trudeau, pioneer in the sanatorium treatment of tuberculosis. In addition to being general commanding the Louisiana Legion at New Orleans in 1861 at the outbreak of civil war, and author of a treatise on the organization of the militia for the defence of the State of Louisiana, Trudeau wrote a book on "Woman and her Diseases", and was the designer of several caricatural statuettes of well-known medical men which are here reproduced.

Dr. Casey A. Wood contributes an instructive paper on "Johannes Baptista Porta (1540–1615), Neapolitan Oculist and Natural Philosopher". Porta was also the founder of the "Accademia degli oziosi" and "Accademia secretorum" at Naples, which recorded a number of scientific discoveries, a writer of plays, many of which were staged with remarkable success, and a collector of natural history specimens, with which he converted his house into a museum. Porta's chief claim to be remembered, however, is that he discovered and described several optical instruments, including the camera obscura. He was also the author of "Magia Naturalis" (1558), by which he intended to destroy some of the prevalent superstitious beliefs, "Phytognomonica" (1583), which is described as a herbal, an advanced text-book on botany, a treatise on comparative biology, and a compendium of surgery, anatomy, medicine and pharmacology, and "De humana physiognomia". in which he proved himself a predecessor of Lavater.

Dr. Karl M. Vogel's paper entitled "Sea Surgeons in the Days of Oak and Hemp" contains a brief account of John Esquemeling, surgeon, buccaneer and writer; Lionel Wafer, another medical man of prominence in buccaneering circles; Thomas Dover, the pirate, who gave his name to the well-known powder; Tobias Smollett, the novelist; John

Atkins, author of "The Navy Surgeon", which contains the first detailed description of African sleeping sickness as occurring in the natives of the Gold Coast in 1737; and Savigny, one of the survivors of the shipwreck of the *Medusa*, which he related with its appalling consequences. In his essay on "Doctors and Gardens", Dr. Frederick Peterson refers to Linnæus, the father of botany, who was professor of medicine at Uppsala before he became professor of botany there; Dahl, his pupil; Gaulthier, of Quebec; Pierre Magnol, professor of medicine at Montpellier; Lobel, of Lille, physician to James I; Leonard Fuchs, professor of medicine at Ingoldstadt, and many other doctors who have given their names to well-known plants.

Yeast

Die Bierhefe als Heil-, Nähr- und Futtermittel
Von Dr. Julius Schülein. (Technische Fortschrittsberichte: Fortschritte der chem. Technologie in Einzeldarstellungen, herausgegeben von Prof. Dr. B. Rassow, Band 35.) Pp. viii + 194. (Dresden und Leipzig: Theodor Steinkopff, 1935.) 9 gold marks.

WHEREAS bakers' yeast remains in the bread after it has done its useful work, brewers' yeast remains as a by-product of brewing and is sometimes a waste product. This is certainly improper, and a great deal of work is going on in all countries to find uses for it either in medicine, or as a food for man and animals. It is claimed that the craze for synthetic organic pharmaceuticals is abating and that the medical man should restudy the old-fashioned natural materials in the light of modern knowledge—above all, yeast.

In England, a material—marmite—made from brewers' yeast has found extensive use for some considerable time, and is freely referred to in books on nutrition. It is one of the two foodstuffs which are rich in vitamin B_1, the other being wheat germ: it was supplied to the Army in the East for the prevention of beriberi during the Great War. In Germany, up to 1914, brewers' yeast was disposed of locally; the value of a pot of yeast, so-called young beer, as a blood purifier was known to the peasants, but most of it was thrown away. During war needs, the under-nourished population took to it, but the demand did not persist.

A very thorough investigation of the vitamin content of brewers' yeast has been made by a number of workers, as well as that of certain amino acids and glutathion. It has been established that the dried material is very rich in vitamin B_1 and B_2 in comparison with the usual foods, and that brewers' yeast extracts properly prepared are far superior to the flesh extracts which are so largely used; indeed these are regarded by some as an unnecessary waste of the animal material.

The author has collected a great deal of information in regard to these points and in particular to the beneficial effects of yeast in cases of malnutrition; his book contains more than four hundred citations to the original literature.

Whereas brewers' yeast is grown in the mash tun along with the nutritive elements derived from the germinated and malted barley, bakers' yeast is produced in quite a different manner under conditions of high aeration from molasses and inorganic nitrogen, the object being to manufacture a product from a single pure culture which is absolutely regular in its character and activity, so that a dough made from a standard flour mixture is properly fermented in a standard number of minutes. It is the aim of the yeast-maker in competition to reduce this time.

Modern bakers' yeast may be described primarily as a gas-making machine. Such yeast dried is eminently palatable, which is scarcely the case with dried brewers' yeast, and successful attempts are now being made to manufacture a special yeast for nutritional purposes in which the vitamin and other therapeutic content of the yeast is enhanced. Apparently the cost of the protein in such yeast is higher than the equivalent quantity as beef or mutton, but the vitamin content is far superior.

It is probable that the public will in future be offered genuine valuable yeast preparations, though some safeguards will have to be discovered to guard them from spurious preparations of inferior or no vitamin content, which they themselves will be unable to recognize.

The sale of vitamin-rich foods containing the requisite accessory factors to our normal unsatisfactory diets is bound in time to present the problem of their supervision. Quick and satisfactory tests of a chemical nature for the vitamins will have to be found in substitution for the present laborious tests on animals, so that the proper public authority may take the control in hand.

Poisons Law

a Guide to the Provisions of the Pharmacy and Poisons Acts 1852 to 1933 and the Dangerous Drugs Acts 1920 to 1932 for the use of Pharmacists and others concerned with Transactions in Drugs and Poisons. By Hugh N. Linstead. With a Chapter upon the International Background of Dangerous Drugs Legislation, by Sir Malcolm Delevingne. Pp. vi+448. (London: The Pharmaceutical Press, 1936.) 5*s*. net.

THE Act of 1933 made drastic changes in poisons law, and the Poisons List and Poisons Rules, issued by the Secretary of State on the advice of the Poisons Board, have brought complications and liabilities to all concerned, in whatever way, with transactions in poisons. The List, excluding esters and salts, approaches 200 entries, some covering ranges or groups of substances; the rules number 33, and 12 schedules are appended. Fortunately, this review is not concerned with the List or Rules as such, but only with the way in which the author explains and amplifies them. They appear involved and interdependent and it is obviously desirable to have them co-ordinated and explained for the assistance of those who are primarily concerned with their practical application. No one is more fitted to do this than he who is the Secretary of the Society which has been concerned with the administration of each Act dealing with poisons in Great Britain, and who is a member of the Poisons Board set up under the latest Act. He has dealt with the subject from the practical point of view and after discussing the question of labelling, he shows the application of the rules to, respectively, retail pharmacy, listed sellers, laboratories, manufacturers and wholesalers, medical practitioners (including dentists and veterinary surgeons), hospitals and manufacturers of animal medicines. In spite of the complexity of the subject and of certain essential repetitions, he has been able to compress these aspects to, respectively, 14, 7, 2, 11, 5, 6 and 2 pages of conveniently large print.

Nothing but praise can be given for completeness, conciseness and clarity. A few *ex cathedra* interpretations are given, and since it may be assumed that these express the attitude of the Pharmaceutical Society, they will probably be acted upon and become standard practice. The paraphrase on p. 98 of the proviso to Rule 23 (2) must be criticized, since it appears to deny completely to a shelf a storage function which the proviso only conditionally restricts. The book concludes with a useful list of poisons and substances containing poisons, with an indication of the special restrictions applying to each. J. R. N.

Alternating-Current Machines

By A. F. Puchstein and Prof. T. C. Lloyd. Pp. viii+582. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 25*s*. net.

IN the preface the authors state that the time devoted in technical colleges to the study of alternating current machines varies between wide limits. It is stated that a definite text-book is chosen and the syllabus is constructed from it. Granting this, it is of great importance that the text-book be comprehensive and thorough. The present volume is a treatise which covers a very wide ground. The authors admit that only a fraction of the material in the book can be studied in the classroom.

We think that, from the training point of view, the treatise would have been much more useful if it had been cut down considerably. Considering the many subjects which electrical students have to study nowadays, and that only a small number of them will take up seriously machine design and operation in their profession, it would have been better for the greater number of students if the authors had discussed only a few typical machines. The treatment is on orthodox lines and will be easily understood by the technical student. Many examples are given, but it would have helped those who try them to have had the answers given and to have more of them worked out.

Die menschlichen Rassen:

eine popularwissenschaftliche Einfuhrung in die Grundprobleme der Rassentheorie. Von Dr. Rudolf Lämmel. Pp. xv+283+48 plates. (Zürich: Jean Christophe Verlag, 1936.) 7 francs.

THIS clearly written treatise on human races belongs to the polemical class of literature, being more concerned in rectifying the errors of German professors than in laying before its readers a scientific presentation of modern ethnology. Readers can best judge of its scientific worth by noting the classification applied to men of the European type. It is proposed to divide them into thirteen races: these are Nordic, Baltic, Alpine, Dinaric, Armenian, the "Faelischen", Turanians, Mediterraneans, Orientals, Indides, Veddahs, Ainos, Polynesians.

The first essential of a classification of objects of any kind is that its groups must be capable of identification and that there is some degree of unity in the total assemblage. The classification in this book breaks these elementary requirements. A. K.

Motivation of Behavior:

the Fundamental Determinants of Human and Animal Activity. By Prof. P. T. Young. Pp. xviii+562. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 20*s*. net.

THIS is a very interesting and sound psychological account of the mainsprings of conduct under the caption of the motivation of behaviour. The work is well developed and well balanced, the evidence clearly put and the argument logically advanced. The author gives his own position by stating that the mind and the brain are one and the same reality, and that motivation is a process of arousing movement by physical energy transformations which are concurrent with behaviour.

At the end of the book is a collection of questions on each chapter—to anyone who has the energy and time to answer these questions seriously they cannot fail to be a great boon. We wish it was a usual practice.

The Harvard Tercentenary Celebrations

HARVARD celebrated its tercentenary on September 18 by a ceremony which was as impressive in its setting as it was comprehensive in its conception.

The scene was set in the "Yard"; for those to whom Harvard is a name, albeit a great name, a word must be said about the actual terrain. The Yard at Harvard, which forms the nucleus of the University, is situated in the town of Cambridge much as Trinity College is situated in Dublin; the buildings are less regularly disposed than those of the colleges at Cambridge or Oxford, and being detached from one another the arrangement into definite 'Courts' or quadrangles is less defined. The quadrangles, in so far as they exist, however, differ from those in the English universities in that they are planted with trees as well as with grass and therefore shaded completely with foliage. Of these leafy areas in the 'Yard', that which most definitely resembles a quadrangle is one bounded by the Memorial Church on the north and by the Widener Library on the south, both noble buildings, each at the head of an imposing flight of steps, and facing one another one hundred and thirty yards apart.

In this court the ceremony took place. The steps of the Memorial Church formed a terraced stage, from the centre of which the addresses were given. In the centre sat also the President of the United States, an old Harvard graduate, and the diplomatic and civic representatives, including Mr. Curley, Governor of Massachusetts. To the right and left sat the recipients of honorary degrees, and in the tiers behind them the delegates from other universities and corporations, and also the representatives of the faculties at Harvard. As the number of delegates was in the region of five hundred, there cannot have been less than one thousand persons who faced the assembly. For it fourteen thousand chairs had been placed in the court. "In the court" is perhaps not a good phrase, for at the back on each side of the Widener Library there is a gap in the buildings, and the rows of chairs stretched out into these two gaps until they were lost to sight beneath the trees.

The actual proceedings lasted about three hours. Over the whole of this colourful assembly hung the menace of storm. The weather for the preceding days had been perfect; but a hurricane was known to be on its way, travelling up the Atlantic coast. Rain-drops fell at the commencement of the proceedings and from time to time during its continuance, but the President, with resolution amply justified by the event, refused to transfer the programme to an alternative one which had been arranged in the event of wet weather. All knew that it was a race with time. Ten minutes before the termination of the sitting the skies broke, but the torrent of rain which poured from the clouds was no more than a reminder of what might have been. To some indeed the conditions may have seemed in a sense an allegory. What better symbol could there be of the determined growth of a University through three centuries of difficulty and strife to its present magnificence than the resolution of its President in carrying the tercentenary celebration to its climax through three hours of menacing storm.

The proceedings opened with a prayer and closed with a benediction—a detailed account of them would perhaps be out of place. Items of particular interest to English readers would perhaps be: (1) The fact that shortly after the opening prayer the chimes of Southwark Cathedral, that in which John Harvard was baptized, were broadcast across the Atlantic and listened to by the audience. (2) The Poet Laureate of England, John Masefield, who travelled 3,000 miles to deliver his tribute in verse . . . which, referring to John Harvard, concluded:

"Would that his human eyes untimely dead,
Freed from that quiet where the generous are,
Might see this scene of living corn made bread,
This lamp of human hope become a star."

(3) The conferment of honorary degrees. The degree of doctor of science was conferred as follows:

Prof. E. B. Bailey—a British geologist whose skilful questioning of the Scottish highlands drew forth revealing answers, telling of the origin of mountain ranges and their evolution in the past.

Dr. Kiyoshi Shiga—the discoverer of the cause of epidemic dysentery, a valiant and effective fighter in the international struggle for the prevention of disease.

Prof. T. Levi-Civita—a mathematician great in accomplishment, an intellectual leader of the land we all revere, the birthplace of the art and science of the present day.

Sir Arthur Eddington—a student of the cosmos who peers within the atom and surveys the expanding universe, an expounder to the multitude of the poetry of modern science.

Prof. A. H. Compton—a physicist who forces light itself to illumine the dark secrets of its still mysterious nature.

Prof. L. Ruzicka—a chemist, daring in his attack, brilliant in his methods, successful in his interpretations of the architecture of Nature's baffling compounds.

Prof. B. A. Houssay—a physiologist noted for his studies of the ductless glands, a leader of science in the new world to the south.

Sir Joseph Barcroft—an investigator of many phases of the respiration of higher animals, a beloved guide to younger men on both sides of the Atlantic.

Prof. C. Gini—a versatile sociologist and statistician who early turned his attention to that most vital problem, the growth of populations.

Prof. B. Malinowski—an anthropological explorer who initiated a new movement for the study of the gregarious habits of the human race.

Prof. J. Hjort—the naturalist of the northern sea, whose studies and explorations have benefited alike the science of biology and the fisheries of his native land.

Dr. F. Bergius—a modern magician, his knowing touch transforms coal to oil.

Dr. N. L. Bowen—a scientific Vulcan, in his laboratory furnaces he measures those forces which once formed our igneous rocks.

Prof. E. D. Adrian—a physiologist whose brilliant experimentation established new principles concerning nerve impulses and the action of sense organs.

Prof. P. M. F. Janet—a pioneer in studying the multifarious phenomena of mental pathology, his systematic analysis founded a branch of psychology.

Prof. J. B. Collip—a skilful biochemist, a bold explorer among the tangled complexities of the internal secretions.

Prof. A. Pannekoek—an astronomer who has gauged the distances of the dark nebulae, an astrophysicist who has assayed the stellar atmospheres.

Prof. E. J. Cartan—a versatile investigator in the realm of pure thought, a mathematician who has advanced his science on many fronts.

Prof. P. Debye—a large-hearted physicist who gladly lends the chemist a helping hand by elucidating the electrical properties of matter.

Prof. The Svedberg—a man who sees beyond the microscope, at his bidding centrifugal forces make giant molecules reveal their size.

Prof. H. Spemann—a biologist who experimented with embryonic tissue and discovered a new approach to those agents which determine organic form.

Prof. C. G. Jung—a philosopher who has examined the unconscious mind, a mental physician whose wisdom and understanding have brought relief to many in distress.

Prof. L. E. Dickson—a fruitful speculator on the significance of numbers, an algebraist noted for his stimulating work.

Prof. R. G. Harrison—an embryologist whose method of transplantation yields new insight into the process of development.

Prof. R. A. Fisher—a student of heredity, who has improved statistical methods and assisted agriculture by the application of his science.

Prof. S. A. S. Krogh—a physiologist for ever probing with new instruments the unknown mechanism of life processes.

Dr. K. Landsteiner—the master of the science of immunology, the discoverer of those fundamental principles which made blood transfusion possible, saving countless lives.

Prof. G. H. Hardy—a British mathematician who has led the advance to heights deemed inaccessible by previous generations.

Prof. A. C. Lawson—a geologist who has ranged widely both in time and space.

Dr. J. H. Northrop—a chemist turned biologist, a skilled manipulator of those catalysts on which life depends.

Dr. F. Silvestri—a brilliant entomologist who has searched many continents to find those parasites which guard our crops.

Prof. H. Fischer—a master builder of molecular structure whose labours tell us why grass is green and blood is red.

Prof. R. Carnap—a philosopher of penetrating insight who lights the way for those who seek through logic the unity of the world.

Sir Frederick Gowland Hopkins—the discoverer of the vitamins, a pioneer in many fields, whose work stands as a symbol of the ceaseless adventure of the human mind.

Among the other awards, the honorary degree of doctor of letters was conferred on the following, among others:

Prof. J. Piaget—a deft inquirer into the growth of those mental processes which mark the gradual development of the normal child.

Prof. V. Gordon Childe—a far-seeing archæologist whose writings allow us to behold the dawn of civilization in Central Europe.

Prof. R. Maunier—a contributor to our understanding of the functioning of social institutions, the director of research into the laws of simpler peoples in the colonies of France.

Prof. P. Pelliot—an intrepid explorer whose examination of the manuscripts and art of central Asia enhances our appreciation of a group of ancient cultures.

Dr. R. M. MacIver—an inquirer into the structure of society, a learned systematizer of our social theories.

Prof. M. I. Rostovtzeff—the social and economic historian of the Roman empire, whose fruitful study of antiquity accumulates for all who read centuries of rich experience.

(4) The most interesting feature of all was the oration of President Conant, a man, be it remembered, of less than forty-five years of age and until two years ago professor of chemistry, the courage and eloquence of which cannot be conveyed in a few words. Starting with the President's conception of the proper ordering of a university, the oration developed into a plea for citizenship based upon the search for truth in all departments of intellectual activity. To the man of science it was interesting to observe that to President Conant the health of a university depends upon the maintenance of a correct balance between four components: student life, the teaching of abstract subjects, professional training, and the search for new knowledge. Typical of the later part of the speech was the demand for "absolute freedom of discussion, absolutely unmolested

enquiry". This note of freedom was struck also by the President of the United States in his speech to the alumni of Harvard the same afternoon. "In this day of modern witch-burning, when freedom of thought has been exiled from many lands which were once its home, it is the part of Harvard and America to stand for the freedom of the human mind and to carry the torch of truth."

So much for the eighteenth of September, but it was only the climax. The proceedings of the two days previous may be passed over, though either of them would furnish matter for an interesting article. Rather would we go back to events still earlier and to a phase of the celebrations which possibly is without precedent.

Harvard determined if possible to make its celebration primarily an intellectual one. Before inviting universities and other corporations to send delegates, it drew out a list "of leading scholars in different parts of the world to a number which we trust will bring to the proposed conference some sixty or seventy men of high distinction from the whole field of learning". These received invitation to take part in a conference the intention of which was expressed in the following words: "It is hoped that we shall succeed in finding a meeting ground on which it will be possible not only for the results of research in detail to be communicated by scholars, to one another, but also for problems which concern a variety of disciplines to be the object of common attack."

The event proved overwhelmingly successful, so far, at least, as the present writer was able to judge from the proceedings kindred to his own subject, and from what he was told concerning others.

These 'proceedings', as indicated in the above quotation from the letter of invitation, fell into several forms. There were addresses on the general aspect of one broad subject such as that by Sir Frederick Hopkins on "The Influence of Chemical Thought on Biology"; "Diabetes as a Disturbance of Endocrine Equilibrium", by Prof. Bernardo Alberto Houssay; "Insect Polyembryony and its General Biological Aspects", by Prof. Filippo Silvestri; "Plants and Civilisations", by Prof. Elmer Drew Merrill. There were sittings devoted to a group of kindred subjects such as that on the "Applications of Chemistry to Biology" in which the individual papers were: (1) "The Use of Isotopes as Indicators in Biological Research", by Prof. August Krogh; (2) "The Formation of Enzymes", by Dr. John Howard Northrop; (3) "Protein Molecules", by Prof. The Svedberg.

There was no possibility of discussion on the great scale, but the effective 'meeting ground' was found in another way—after the communications, groups of those interested in the subject met and thrashed the matter out, or tried to do so. To take an example, after a communication on "The Fundamental Nature of the Respiratory Rhythm", a group consisting of two experimental psychologists, two pharmacologists, one physiologist and three anatomists had a most fruitful discussion on the initiation of neuro-muscular function in the fœtus, and one which will probably clear up many existing divergences of opinion. Such in its small measure admirably fulfilled the desire of Harvard "for problems which concern a variety of disciplines to be the object of common attack".

On this great scale, the same object was attained by the institution of symposia. These were classified as follows (Nos. 4 and 5 really were not symposia in the same ordered sense as 1, 2 and 3; they were groups of communications of the type of and including those already discussed):

(1) Factors determining Human Behaviour.

(2) Authority and the Individual.

The State and Economic Enterprise; Stability and Social Change; The Place and Functions of Authority; Classicism and Romanticism.

(3) Independence, Convergence and Borrowing in Institutions, Thought and Art.

Europe and the Near East; The Middle Ages; East and West.

(4) Biological Sciences.

Various Aspects of Biology; Experimental Morphology; Parasitism; The Applications of Physical Chemistry to Biology.

(5) Physical Sciences.

Mathematics, Astrophysics, Cosmogony (Sessions of the American Mathematical Society and the American Astronomical Society); Theoretical Physics; Cosmic Radiation; Nuclear Physics; Geology and Geophysics; Chemistry; Industrial Chemistry; Communication Engineering.

The first of the above symposia was attended by the complete conference in joint session and was indeed the inaugural meeting. The remaining four represented the four divisions into which learning was divided for purposes of convenience—human relations, arts and letters, biological sciences, and physical sciences.

As an example of how the plan worked in detail, the first symposium may be taken. The intention was to sample various aspects of the activity of the human nervous system, from the most simple to the most complex. The opening paper was by Prof. E. D. Adrian on the objective physiology of "The Nervous System". This was followed by papers on "Hormones in Relation to Human Behaviour", by Prof. J. B. Collip, "Les principaux facteurs determinant l'évolution intellectuelle de l'enfance à l'âge adulte et de la genese des principes de conservation", by Prof. Jean Piaget, "Psychological Factors determining Human Behaviour", by Prof. Charles Gustav Jung, "La force et la faiblesse psychologique", by Prof. Pierre Marie Félix Janet, "Logic", by Prof. Rudolf Carnap, "An Example from the Evidence of History", by President Emeritus Abbott Lawrence Lowell, and finally "Culture as a Determinant of Behaviour", by Prof. Bronislaw Malinowski.

The last of these took the form of an evening lecture. Other public lectures treating of subjects of general interest were by Frank Baldwin Jewett, of the Bell Telephone Laboratories in New York, on "The Social Implications of Scientific Research in Electrical Communication"; by Prof. Wm. Berryman Scott, on "The Laws of Mammalian Evolution"; by Sir Arthur Stanley Eddington, on the "Constitution of the Stars"; by Prof. G. H. Hardy, on "The Indian Mathematician, Ramanujan"; by Prof. E. J. Dent, on "The Historical Approach to Music"; by Prof. Corrado Gini, on "Authority and the Individual during the Different Stages of Evolution of the Nations"; by Prof. John Dewey, on "Authority and Resistance to Social Change"; by Prof. W. E. Rappard, on "Economic Nationalism"; and by Prof. Johan Hjort, on the "Biology of Whales".

Reviewing the activities of the congress, or such of them as fall within the scope of a biologist, it can only be said that the event far exceeded what might have been expected of it. It may be doubted whether any congress covering so wide a field has ever succeeded in at once reaching a level so sustained in matter, and in manner so intelligible to those not acquainted with the particular and specialized techniques of those who rose to so high a level.

Lastly, a word as to the hospitality poured with both hands upon the members of the congress. It is difficult to know where to begin or end in treating of it. American hospitality is the high water mark; to say that it reached the highest level of American hospitality is no less than the truth. One item, however, must be mentioned specifically, namely, the orchestral concerts, three in number, given by the Boston Symphony Orchestra. Two were instrumental, in the third the orchestra combined with the chorus of Harvard University and Radcliffe College. All were a sheer delight. At the close of the last concert, just before "Fair Harvard" was sung, President Conant walked up the hall, ascended the platform, shook hands with Dr. S. Koussevitzky, whose skill and enthusiasm as a conductor had been so largely responsible for this feast of pleasure. Dr. Conant said a few words, ending as follows: "I wish to say just two words 'Thank you'." A fitting ending, for there is no delegate who can have left Harvard with any other thought in his mind. Harvard—Thank you!

The Patterns of Experience*

By A. W. Wolters

SUMMING up his important contributions to the psychology of perception, Prof. E. Rubin demonstrated, in a paper devoted to the 'ways of seeing' read before Section J of the British Association at Norwich last year, that perceptual cognition is shot through with suggestions of movement and direction which are not reducible to the geometry of the object. The mind contributes structural principles to its own experience.

Like many scientific theories, this was not new. Many besides Rubin, and many earlier than he, have suggested that the mind, at least in part, makes its own experience. The value of his contribution lies in the beauty of his experimental development of the theme, and in the detailed application of it. But at least one of his demonstrations at Norwich was so new as to be thrilling. Those who were present will remember vividly how we were brought to recognize that pictures in European art have a definite left-to-right character, upon which their meaning and æsthetic appeal largely depend. I reported this to Mr. Betts, the head of the School of Art in the University of Reading. We went through his stock of lantern slides, and found that in nearly every case Rubin was clearly right. But our most exciting moment was that in which we discovered a drawing in which Rembrandt had gone astray. My colleague suggests that Rembrandt made his sketch from a mirror, a quite usual method, so that having posed his model correctly—that is, as Rubin would have had him do—and being absorbed by the technical problems of his sketch, he overlooked the extraordinary and unpredictable effect of the lateral inversion.

---

* From the presidential address to Section J (Psychology) of the British Association, delivered at Blackpool on September 11.

It seems clear that there are pre-established manners of seeing, and we must expect the same to hold in the other modalities of sense. It appears that perception can be shaped by factors extrinsic to the material experienced. Under their influence the mind is creating, is actively patterning its experience, so that in some sense and to some degree (the limits being determinable by experiment) the mind makes the world it knows. To speak a little dogmatically, I hold that the mind informs its sensory material, making the percept consistent with certain subjective principles. This implies that the patterns of experience are in some sense already latent in the subject's mind as he confronts the world. Can we say how ?

Alas, not very well. We must be content for the present with a small but useful advance to be made along the following path. If one says that perceiving is a response of the organism, meaning what one says, it follows that the distinction between cognition and conation is not an ultimate one. The general utility of the traditional division is not in question, but in the end we have to recognize that the process of coming to know is an activity, a piece of behaviour linked up with and subordinated to other behaviour. Conation *must* be the fundamental concept, because the first duty of every organism is to remain alive, and it needs to manage and control its environment to that end. Let us look for a moment at other forms of behaviour.

It is agreed that behaviour exhibits certain regularities of sequence which entitle us to formulate laws. In describing the phenomena, the phrase which comes most readily to the tongue is that they exhibit patterns. The word has of recent years been very freely used. It requires no technical knowledge to understand the statement that a man's business activities show a constant pattern, no matter how varied the details with which he has to deal at different times. Our insight into the character of acquaintances mainly rests upon the observation of their behaviour patterns. It is very difficult to describe them, and still more difficult to analyse them, but they are easily recognizable. They are, in fact, the constancies without which social life would be impossible.

The outstanding example of patterns of behaviour is presented by the instincts. In them we have themes which can be recognized as essentially the same while the details of the activity vary thoroughly, just as the theme of a symphony can be recognized through its development. But to say this is to apply the term 'pattern' as an objective description, and not as an explanation. Whether in this field you prefer to speak of urges and drives, or of fields of force and closure, is indifferent to the present argument, which requires only two points conceded to it : first, that these patterns of behaviour are observable, it being in virtue of them that the adjective 'instinctive' is applied, and, secondly, that the character of the organism is among the causes which produce them. We note that the behaviour of the human individual displays patterns which are similar in their outline to those of animals, and which, arguing from them, we must assert to depend upon the connate character of the organism.

To argue the obvious a little more fully, if a pattern is observable in behaviour, it must be dependent either upon the detailed events themselves, or upon the organism. In many cases, such as the behaviour of insects or nest-building in birds, there seems to be no sense in the first alternative, and consequently we take the patterns to be determined by the nature of the organism. This is to assert that the pattern is latent in the organism ; but not after the manner of a 'blue-print'. The latent pattern is not open to inspection. It exists, to use an old and respectable term, formally. There is a character of the organism which gives a distinctive pattern to its reactions. But there are also patterns observable in acquired activities, and in this case we have an everyday term to designate the quality of the agent which produces it. We call it a skill, and regard it as inherent in the subject whether he is or is not engaged in the activity at the moment. But once more it is not inspectable as the pattern of the activity is. All we can observe is that A by economical and coherent actions consistently achieves success in a given field, while B as consistently fails in it. Believing that all phenomena have a cause, we ascribe to A a skill which B lacks. So far as language goes, we can say either that A is skilled, or that he possesses a skill. Both expressions are admissible, but I would suggest that the former is better in psychology, since we can neither observe, nor by deduction describe, a skill in itself. When we attempt to do so we usually find ourselves describing again the pattern of the activity. Let us take a skill to be a character of the individual, a manner in which he has been psychologically shaped by racial or individual experience. To say that a person is skilled means that he is prepared to deal adequately with situations of a particular kind, but prepared in an outline, flexible manner which is sensitive to the varying details of the moment. Skill is in this respect on a higher plane than tropism, reflex or habit. The organism's skill is displayed in controlling and organizing material on the way to achieving a goal.

Now we can return to our original problem of perception. No present-day psychologist can be content to regard perceiving as no more than reflecting the material world, or as a process to be studied in isolation. It is a preparatory reaction, prior to more far-reaching activities, its immediate goal being the organization of sensory data into manageable forms. So we come to the conclusion that the predetermined 'ways of seeing' of which Rubin spoke belong to the vast family of skills, and can be treated with the others. The range of processes in which the pattern of behaviour, and the pattern resulting from the behaviour, depend upon the mental characteristics of the agent would appear to cover the whole extent of human life.

At the London meeting of the British Association in 1931 I read a paper advancing the hypothesis that what is termed conceptual thinking can be dealt with in terms of skill, saying that what are termed concepts are best considered as outline preparations for response, and not as mental entities. I endeavoured to show that the behaviour of animals displays patterns parallel with those of a higher grade in human beings. I introduced the term schematic preparation, or more shortly 'schema', as a name for this subjective character. Five years later, fortified by the parallel advance of Prof. F. C. Bartlett in another part of the field, I am bold enough to claim that our conception will cover all parts of animal and human psychology, pulling together into a system many heterogeneous results.

Can we apply the outcome of this discussion in the field of social psychology ? The term 'social pattern' is in common use, and perhaps is employed with dangerous facility. In the first place, it appears to mean an observable system of relationships between individuals and their activities, constituting a unity of a higher order of complexity than that of any one of its members. Secondly, the social group is a part of the environment of each of its members and of persons who make contact with it from outside. It is a system of facts to which individuals have to adapt their behaviour. In this it is parallel to the inanimate environment, and since the principles of behaviour will resemble those already encountered, the matter may be left for a moment at that level. Thirdly, social groupings present a puzzling combination of determinacy and flux. To live in society is rather like rowing in rough water. Within a quite characteristic pattern of the whole there is an inconvenient mobility of the elements, which requires continual variability of response. The patterns of society are determinate but dynamic, and to react successfully to them demands skill.

To deal with this problem in a little more detail I turn to another paper read before Section J at Norwich, one by Prof. T. North Whitehead, since published in *The Human Factor*, 9, 381. A group of five girls working at the same tasks came in time to form a real social group with a complex but readily discernible pattern. An objective record of it was obtained by studying the relations between the output of individuals, and the investigator was able to reduce these to a clear diagrammatic form. Since conversation is the chief instrument of social relationship, the seating arrangements proved largely decisive for the pattern. When an experimental change was made in the seating order, the social and psychological pattern was broken and a new one had to be formed, output being adversely affected during the process.

Prof. Whitehead's interesting report is concerned mainly with the objective study of the group. There are, however, important implications on the subjective side. In the first place, like everything else, society is only apprehended by individuals, whose perception will be shaped in ways analogous to those revealed by Rubin in simpler material. This is the common handicap of all science, and no more need be said of it than to remind ourselves that each person must react to society as *he* sees it. A more important matter is that society, whose dominating influence we realize more and more, has proper significance for psychology only in its impact upon individua lives. It is, indeed, only actualized in those moments. Its components are individuals acting and their behaviour is informed by the principles studied earlier. Yet their activities form a system and we have to reconcile that with individua psychology.

A group only exists in virtue of conative tendencies developed by individuals in the course o accommodating their behaviour to each other's It requires skill to live socially, and I see no reason why we should not treat this as we did others Social skills are predetermined schematic preparations for adaptive responses to situations presented by the presence of other persons, whose behaviou forms a reciprocally interacting system, and so i is the psychological character of individuals which chiefly determines the social pattern. I should like to adapt a famous conclusion of Rousseau, and say that society becomes a topic for psychology jus because it exists immanently in the minds of it members. Whitehead's subjects did not build up a real unified group merely through the seating arrangements. The effects of the removal of th one who had become the leader show this. Th unity of the group broke up, and though he successor became even more popular it was neve fully reconstituted. So, at least, the writer maintains. But I venture to think that there wa formed a new and firmly integrated pattern of kind too subtle and intimate to be revealed by the test of correlative fluctuations of output. How otherwise can we account for the odd fact that when the former leader came back to replace her temporary successor the group was entirely broken up through the newly developed hostility to her, formerly the outstanding member of the group ?

What the experiment depicts is the gradual orientation of individuals to each other—in other words, their learning ways of living with each other. When the social environment is changed, a new set of behaviour tendencies has to be established, until in the final setting an environment was found to which the girls could not react successfully. But they had done so at an earlier stage, and we must conclude that in the intervening period some change had occurred in the other girls. The earlier objective conditions were repeated, but there was no unity. Can we avoid the conclusion that the unity had existed in the minds of the members, and those minds had changed to such an extent that the old reactions had become impossible ? An objectively observable group pattern is a product of the skill-characters, or behaviour schemata, of the constituent members. So a problem of group psychology reduces itself to one of individual psychology.

Social patterns are largely manifested in institutions and current ideas, and often in combinations of the two. The English Common Law provides an excellent example of the last. This remarkable invention of our race has been maliciously described as consisting of a vast body of decisions and pronouncements, all readily deducible from a very few simple and universally accepted principles, though no one knows what they are. I cannot say whether this description is true, but there is no psychological difficulty in it. Common Law principles are the ways of living together developed by English people, and like all skills (for skills they are) they were developed in pursuit of ends which did not include the purpose of inspection.

Pursuing a purpose and thinking about the pursuit are quite different processes. So for a long time, possibly always, they would not be amenable to analysis or description. To describe them necessitates the development of a new skill directed to the material provided by the prior one. This is in essence Bartlett's illuminating distinction between schemata as the instruments of reaction and schemata as objects to which reaction is directed. The Common Law is the expression of the directive tendencies of citizens bent on living together along determinate lines, though they may have never reflected upon them. Probably the majority of Englishmen have never heard of the Common Law, though it governs their lives in so fundamental a manner. It is quite usual to find that people who evince a great determinateness of behaviour are unaware of the principles which govern them. Why should they pause in the process of achieving their ends, if all is going well, to 'turn round upon the schemata' which are serving them ?

There is a danger in any form of expression which suggests an opposition between social psychology and individual psychology. The field marked out by the former term is one proper for the specialist, but it remains the study of individuals acting socially. It would avoid the risk of over-abstraction, with possibly something of mysticism arising from it, if we were satisfied to speak of the psychology of social behaviour. At bottom it is the study of the development and nature of schemata employed in orientation to other behaving organisms. They, too, act from schemata, and if they are to live together they must effect a considerable degree of uniformity. So the social pressure upon individuals is intensified by the establishment of institutions which are the outward patterns resulting from the psychological characteristics of the members of the group, and in return a potent means of shaping the next generation. Here the vital problem of society resembles that of the individuals (as must be the case) ; it is that of keeping the outline preparations for adaptive behaviour sufficiently fluid to be sensitive to variations in the problems presented. The Hegelian limit of efficiency is inflexible specific habit, which is a skill so perfectly developed as to become a hindrance.

Now to summarize briefly the thread of this discussion. The subject-matter of psychology is taken to be the activities of the individual organism striving to maintain its full integrity in the universe in which it lives. To obtain control it must organize the presented material of experience into patterns manageable by it, and to this end it develops skills in its activities. Naming these skills by a word not inconvenienced by overmuch usage, we have called them schemata, and the system of a person's schemata embodies all his experience up to the present moment, and determines the direction of his future experiencing. The patterns of experience are formed by them, though not independently of objective conditions. Thus in outline the 'ways of seeing' and the 'ways of living'—whether socially or otherwise—are reducible to a common psychological genus.

The value of this view to me lies in its providing a unitary point of view from which, it is hopefully claimed, one can survey the whole extent of psychological study. At least it may prevent a born eclectic like myself from degenerating into a kind of scientific jackdaw. So I invite you to regard experience, in the fullest sense of that word, as formed in a complex of patterns largely made by the experiencer, patterns in some cases interlacing, in others forming a hierarchy of increasing generality. Or, to start from the other end, let us take our science to be the study of all the detailed embroideries upon that most common and most comprehensive of patterns, the formula of which runs: He was born, and strove to master his world for his own safety; he mated, fought for his offspring, and died.

Campbell Swinton and Television

By Dr. J. D. McGee

THE successful inauguration by the British Broadcasting Corporation of the high-definition television transmitting station at Alexandra Palace has focused the attention of the technical world on the successful development of the all-electric, instantaneous system of transmission. The degree of success achieved shows that the cathode ray transmitting tube has at last emerged from the research laboratory to take its place as the complement of the receiving cathode ray tube. The latter is well known, and has been recognized for some years as the most effective means for picture reception, and is now a highly developed commercial product. Modern television technique, which will withstand the criterion of the flickerless talking picture, both from the producing and reception points of view, has only been made possible by the development of the receiving and transmitting cathode ray tubes. This development is the result of improvement in technique brought about by the work of many scientific investigators in research laboratories throughout the world.

The manufacture of the modern cathode ray tube for picture reception has evolved slowly as improvements in vacuum technique, glass manufacture, fluorescent materials have been made, while the transmitting tube inherits also the wealth of developments in photo-electric technique. Besides these key units, the whole television equipment—amplifiers, scanning oscillators, pulse generators, cables, radio transmitters, etc.—have each been improved to a stage where they are capable of dealing with the enormous frequency bands, exacting phase conditions, etc., which are necessary for the production of high-definition flickerless picture. This has been achieved by improvement in valve and circuit technique spread over the last twenty years.

The object of this article is to pay a tribute to the memory of a man who probably thought more deeply, clearly and disinterestedly about television than any other of his time and who, had he but lived six years longer, would, I believe, have agreed that his life-long dream had at last come true.

The late Mr. A. A. Campbell Swinton was the first to propose[1] an all-electric system of television in 1908, and continued to urge its claims[2] up until the time of his death in 1930. Sir Richard Gregory has recently reminded us of Campbell Swinton's early suggestions in connexion with television[3], but it might not be redundant to show how Campbell Swinton continued to develop his ideas as technical methods advanced during the remaining twenty years of his life. He first suggested the idea in a short letter to NATURE in 1908[1], later explaining and amplifying it in his presidential address to the Röntgen Society on November 7, 1911[4]. This plan of twenty-eight years ago only required the application of modern technique to become the non-mechanical system now installed at Alexandra Palace, and still in course of development in Germany and America.

It is worth while quoting at some length from the published papers of Campbell Swinton in order to emphasize not only the remarkable accuracy with which he visualized his scheme, but also the kindly unassuming manner in which he presented it to the world.

Campbell Swinton's definition of television is worth noting when considering modern developments, in order to appreciate the difference between television proper and telekinematography. He defines television thus[5]: "If you point a photographic camera at any view or object, whatever is in front of the lens is depicted on the ground glass screen, and what I mean by television is some method whereby what is depicted on such a screen, with any motions or other changes that may be taking place, is electrically transmitted to a distance and made reappear instantaneously on a similar screen at the distant station." This conception of television is implicit in all his early publications.

Referring to a letter from Mr. Shelford Bidwell in NATURE of June 4, 1908[6], in which the difficulty of obtaining synchronism with mechanical television systems was discussed, Campbell Swinton observed[1]:

> ". . . this part of the problem of obtaining distant electric vision can probably be solved by the employment of two beams of kathode rays (one at the transmitting and one at the receiving station) synchronously deflected by the varying fields of two electromagnets placed at right angles to one another and energised by two alternating electric currents of widely different frequencies, so that the moving extremities of the two beams are caused to sweep synchronously over the whole of the required surfaces within the one-tenth of a second necessary to take advantage of visual persistence.
>
> "Indeed, so far as the receiving apparatus is concerned, the moving kathode beam has only to be arranged to impinge on a sufficiently sensitive fluorescent screen, and given suitable variations in its intensity, to obtain the desired result.
>
> "The real difficulties lie in devising an efficient transmitter which, under the influence of light and shade, shall sufficiently vary the transmitted electric current so as to produce the necessary alterations in the intensity of the kathode beam of the receiver, and further in making this transmitter sufficiently rapid in its action to respond to the 160,000 variations per second that are necessary as a minimum.
>
> "Possibly, no photoelectric phenomenon at present known will provide what is required in this respect, but should something suitable be discovered, distant electric vision will, I think, come within the region of possibility."

This 1908 statement is, undoubtedly, the first published suggestion of a television system which has now been developed on a commercial basis to produce pictures of even higher order of definition than the inventor then proposed as a satisfactory minimum. In the elaborated account of this suggestion in his lecture to the Röntgen Society in 1911, Campbell Swinton gives more details of his proposed transmitting tube, and while it is crude in comparison with a modern transmitting tube, anyone who is familiar with the development of the subject will agree that it was an enormous step in the right direction. It is characteristic of the man that, in proposing his suggestion, he emphasized that[4]:

> "it is an idea only, and the apparatus has never been constructed. Furthermore, I would explain that I do not for a moment suppose it could be got to work without a great deal of experiment and probably much modification. It is, indeed, only an effort of my imagination, and can be useful merely as a suggestion of a direction in which experiment might possibly secure what is wanted. What, however, is claimed is that, so far as I am aware, it is the first suggested solution of the problem of distant electric vision in which the difficulty of securing the required extreme rapidity and accuracy of motion of the parts is got over by employing for these parts things of the extreme tenuity and weightlessness of cathode rays".

What must astonish the modern television engineer is the accuracy of Campbell Swinton's idea, when he reflects that, at the time it was suggested, radio communication was in its infancy, radio valves practically unknown, vacuum technique very primitive, photo-electric cells very inefficient.

In the period following the Great War, much time and money was spent in developing mechanical systems of television to the present high limits of mechanical efficiency, but the all-electric system has proved, after a comparatively short period of development work, to be much more powerful.

Campbell Swinton repeatedly pointed out the limitations of the mechanical methods, and repeatedly urged that the development of the all-electric system should be taken up seriously by some large industrial research laboratory. "There are, at any rate," he wrote[7], "no theoretical objections to the scheme, and it is now for some ingenious experimenter to work out the details of the apparatus and to give the world some form of television by this means."

It may justly be asked—"Why did not Campbell Swinton develop his own scheme ?" The answer is twofold—first, that he did carry out experiments along lines which have recently proved successful, and second, that physical technique was at that time quite inadequate to deal with the problem. In a letter to NATURE of October 23, 1926[8], Campbell Swinton wrote :

> "I actually tried some not very successful experiments in the matter of getting an electrical effect from the combined action of light and cathode rays incident upon a selenium-coated surface. . . . The transmitting apparatus consisted of a home-made Braun oscillograph in which a metal plate coated with selenium was substituted for the usual fluorescent screen, the image to be transmitted being thrown by a lens upon the selenium surface, and the end of the cathode ray beam being caused electromagnetically to traverse the projected image. Experiments were also tried in receiving with a Braun tube which I purchased in Germany, but in its then 'hard' form it proved very intractable."

It is interesting to note that this actual experiment has been repeated recently in the Research Laboratories of Electric and Musical Industries Ltd., under the direction of the present writer, and has proved successful. Two important features of the modern transmitting tube are described in this short note, namely, the use of a 'signal plate' and the projection of the optical image on to the same surface as is scanned by the electron beam—another step in the right direction.

This solution of the problem of high-definition television was not a 'one-man-job', as Campbell

Swinton saw clearly[9], but one which could only be solved by the close co-operation of a large band of research workers having at their disposal the facilities of a well-equipped research laboratory. The problem has been attacked during the last decade in many of the large industrial research laboratories in America, Germany and Great Britain, and the progress in many of these organizations has been roughly parallel, but it is fitting that Great Britain should be the first to inaugurate a public television service employing the system which was first outlined twenty-eight years ago by a distinguished British scientist.

Stratosphere Flight

THE recent world's height record, for aeroplanes, of 49,967 ft., set up by Squadron-Leader F. R. D. Swain, R.A.F., piloting a Bristol monoplane fitted with a special type Bristol Pegasus engine, has served to focus a certain attention upon the question of flights at great altitudes, and the possible advantages to be derived therefrom.

The most obvious gain comes from the reduction of the resistance to the aircraft's motion as the density of the air to be displaced decreases, which, if other conditions remained the same, would result in increases of speed of a valuable order. For example, in round figures, an aeroplane of maximum speed 180 miles per hour at sea-level would travel at 550 miles per hour at a height of a little more than ten miles. This is equivalent to London to New York (3,000 miles) in 5½ hours, neglecting the time taken to climb to and descend from that altitude.

Other probable advantages are a relative wind in a direction opposite to the rotation of the earth, if a shear effect in the belt of atmosphere rotating with the earth may be assumed; the absence of meteorological and electrical disturbances with their effect upon accurate navigation, that would also allow routes to follow the shortest line from point to point irrespective of the conditions upon the earth's surface, as for example across the polar regions; and the psychological effect of constant sunshine, lack of clouds and equable temperature conditions are possibly not to be ignored.

The principles upon which the flight of the present-day heavier-than-air machine are based, however, make use of the density of the atmosphere in several ways in which its rarefaction at great heights would be a definite disadvantage, and may possibly set a limit upon entering the stratosphere which will make it not worth while, at least as a commercial transport proposition. The importance of doing so for the purpose of research into the physical conditions comes within a different category.

The power plant gives the machine a forward motion through the medium of an airscrew, this being required in order that the circulation of air around the lifting surfaces may be set up, resulting in the necessary lift and control. A reduction in air density will lessen this thrust and thus reduce the lift indirectly by reducing the speed, in addition to the direct loss of lift. Further, use of full power would result in excessive rotational speed of the airscrew due to the thinness of the air. Variable pitch propellers, already a practicable proposition to a limited extent, will help in this respect.

The internal combustion engine, the present-day power plant, requires a definite weight of oxygen for the proper combustion of its fuel. The rarefied and poor quality air can be forced into the engine, up to a certain limit, by super-chargers, and after this it does not appear to be impossible to carry a supply of oxygen under pressure to make up this deficiency, more especially as a supply will probably have to be carried for the occupants of the aeroplane. The physiological requirements of the passengers and crew will call for extra size and weight of the cabin, which will have to be of sufficient capacity for the required change of air, to carry apparatus for storing the oxygen and for absorption of the carbon dioxide and moisture exhaled, and will almost certainly have to be heat insulated. This may be against the low temperature of the surrounding atmosphere, or against heat generated by the friction set up by the rubbing of the air at these high speeds. Which will predominate, and how far one will balance the other, will depend upon the heights and speeds attained.

This state of affairs is already partly achieved, and its consummation does not appear to be beyond the bounds of possibility, at least, as a scientific experiment. As an everyday transport proposition, experiment alone can settle whether the balance between total loads carried, and the part left for useful carrying capacity, after the elaborate equipment is installed, and the effect of the artificial conditions, accelerations and such discomforts upon the passengers, will make it worth while. It has been suggested that under these conditions, and with existing materials and aerodynamic design as now accepted, there are theoretical reasons for thinking that a limit will occur upon speeds at about 650 miles per hour.

To travel without this limit in the higher regions of the stratosphere will necessitate the use of some new method of propulsion, not dependent upon the presence of air for its functioning or the application of its tractive effort. The obvious solution that comes to the mind in this case is rocket propulsion. A certain amount of experiment has already been carried out in this respect; one quite serious proposal was made not long ago to fire mails from France to England across the Straits of Dover. The principal problem to be solved is that of control of the orientation of the machine while in flight. If this calls for the presence of the human element, the effect of the terrific accelerations at the start and finish cannot be ignored. Should this prove insuperable, automatic control of some kind does not appear impossible, but it will necessarily exclude passenger traffic.

A possible midway step between the two that has often been suggested is reported to be under construction and nearing completion in Soviet Russia. An aeroplane fitted with the usual internal combustion engine and propeller also carries rocket tubes. These will continue to give the necessary forward movement by reaction propulsion after the normal tractive effort has become negligible by reason of the reduction of the density of the air. This is not the complete rocket propulsion, and its efficiency would still appear to be largely dependent upon the air density for its reactive effort.

With regard to flight in the stratosphere by lighter-than-air craft, this is a much simpler problem. It becomes a matter of calculation as to the displacements of the balloon at the anticipated air density at the maximum height proposed, and the design of the envelope and the passengers' car to withstand the pressure differences. Such flights are of importance for the investigation of conditions in the upper air, and the perfection of such meteorological information will be of importance in the development of heavier-than-air craft under similar conditions. There does not appear to be any direct value in them from the point of view of controlled air travel. The height record for free balloon travel in the stratosphere is 72,395 ft., reached by Captains Stevens and Anderson, United States Air Corps, in the balloon *Explorer II* on November 11, 1935.

Obituary

Mr. J. W. Gordon, K.C.

MR. JOHN WILLIAM GORDON, K.C., who died in his eighty-third year on September 21 last, was the son of Mr. John Lewis Gordon, and was called to the Bar in 1884. He was a well-known Patent Law expert and was always strongly attracted to scientific and technical investigations. He was a member of the Commission appointed to inquire into the pitch industry of Trinidad; assisted in drafting the Patent Act of 1907; was formerly honorary secretary of the Royal Microscopical Society; received the gold medal of the Society of Engineers for his work on railway surveying by photography; and throughout his long life he never lost his interest in optical and allied subjects. It is, perhaps, by his work in connexion with microscopic resolution that he will be best remembered in the future.

Mr. Gordon also did some interesting and valuable work with regard to the plotting of surveys from air-photographs, and in his book "Generalised Linear Perspective", which was published in 1922, he describes how he rediscovered a method originally devised by Brook Taylor (of Taylor's theorem) two hundred years ago. Briefly, the method is this; if there are three points in a line in the cartographic field and the real lengths of the two segments are known, then it is easy to calculate the position of the point where the given line cuts the horizon; and if there is available a second similarly divided line, the horizon can be drawn.

The system is essentially a point-by-point method of plotting, and there are cases in which it may be of value, especially when the photographic plate is considerably tilted. But Mr. Gordon was inclined to claim somewhat too much for this method, which, after all, is only one of many. Nowadays we are in the more intricate region of stereoscopic air-photography and of mechanical plotters, and, except in very simple cases, we have left point-by-point methods behind us. But Mr. Gordon's book has its own place in the history of the subject, and perhaps that is as much as it will be possible to say of the writings of most of us.

Mr. A. E. Clarence Smith

It would be difficult to over-estimate the contribution made by the late Capt. Alton Clarence Smith, who died on September 16 at the age of forty-nine years, to the development of the Department of Chemistry at University College, Southampton, during the seventeen years in which he was responsible for the teaching of physical chemistry.

Mr. Clarence Smith was a man of wide culture, interested in biology as well as in physical science. He had also an unusual degree of mechanical skill and a marked taste for architectural design, gifts strikingly shown in the planning and equipment of the laboratories which he designed for the use of his students. His research work lay chiefly in the domain of photomicrography, on which he was an acknowledged authority, and his papers on this subject in the *Journal of the Quekett Club* and similar publications led to his being frequently consulted by biologists and others interested in the use and construction of microscopes.

But Clarence Smith was in the first instance a teacher, and it is as a great teacher of physical chemistry that he will be remembered by the students who in successive years listened to the extraordinarily clear discourses with which he illuminated the difficult field of study embraced in physical chemistry. He took infinite pains in the presentation of his subject; the notes which he prepared for his lectures were models of clear thinking and accurate expression. He was genial and sympathetic with his students, appreciating fully their difficulties, and he had in full measure their affection and respect. His knowledge, experience and that critical judgment which was one of his outstanding characteristics, were always at the service of his colleagues; the research work of the Chemistry Department at Southampton owes a great debt to him for the interest, the counsel and the generous help which he gave so freely.

The loss which the death of Clarence Smith brings to the teaching strength at University College, Southampton, is very great; but, above all, he will be missed for the charm of his personality, from which there radiated always the virtues of sincerity, courage and goodwill. D. R. B.

We regret to announce the following deaths:

Mr. Alan Blakeway, director of the British School of Archæology at Athens, on October 9, aged thirty-eight years.

Sir George Buchanan, formerly senior medical officer in the Ministry of Health, on October 11, aged sixty-seven years.

Prof. W. E. Praeger, emeritus professor of biology in Kalamazoo College, Michigan, known for his work in ecology, on August 13, aged seventy-two years.

Prof. Camille Sauvageau, formerly professor of botany in the University of Bordeaux, aged seventy-five years.

News and Views

International Relations promoted by Broadcasting

An international convention on the use of broadcasting in the cause of peace was adopted at a Conference at Geneva on September 23 and signed by representatives of eighteen countries. Soviet Russia signed with some reservations, but Hungary did not sign the convention although the Hungarian delegation had taken part in the proceedings throughout. The Italian delegation, which had also followed the proceedings with close interest, had previously been instructed to withdraw from the conference, and left expressing good wishes for its success. The text of the convention does not differ essentially from that prepared by the International Institute of Intellectual Co-operation at the request of the Assembly of the League of Nations. There are fifteen articles, of which six deal with matters of substance. The purpose of the convention is to ensure that broadcasting is never used in a manner prejudicial to good international understanding. A distinction is made between messages in the nature of a direct appeal to the inhabitants of another country and those designed primarily for national listeners. The former are prohibited in so far as they incite to acts incompatible with the internal peace or security of the territory of another party. States are bound under the convention to prohibit any broadcast likely to prejudice good international understanding by statements the incorrectness of which is, or ought to be, known to those responsible for the broadcast and to ensure that such statements are rectified immediately. Under a special provision, Governments agree, especially in time of crisis, to ensure the accuracy of the information concerning international relations broadcast within their territories. Provision is also made for the exchange of information calculated to promote a better knowledge of civilization and the conditions of life in the countries concerned and also for arbitration and conciliation procedure in the event of a dispute.

Co-operation between Oxford and Cambridge

In Convocation at Oxford on October 7, the Vice-Chancellor announced a scheme for co-operation in academic work which has been discussed by the governing bodies of the Universities of Oxford and Cambridge. It is proposed to promote legislation to allow students, whether undergraduate or post-graduate, from either university to go to the other for special courses of study and to keep residence while doing so. Facilities available at one of the universities only may thus be made available for common use, and studies of insufficient general interest to make it worth while for each university to have its own department need not be duplicated; it is possible that some existing duplication can be eliminated and the funds thus set free used for urgent needs. At first sight, this proposed innovation seems a great break with the traditions of the older universities; but there is no doubt of its excellence in principle. The college authorities, it is expected, will be less in favour of it than the university, but this is probably all to the good. They will see to it that the proposed freedom to migrate for a term or more will not be abused; that, in fact, only those who will greatly benefit by the change will be encouraged to enjoy it. With respect to facilities for instruction and research in science, it is likely that Oxford students will benefit more than Cambridge from the new proposal, at least at the undergraduate stage. The honours man at Oxford in science has generally but one subject to specialize in and consequently has time to take extra courses elsewhere; at Cambridge he is partly occupied with other subjects: and, of course, at Cambridge facilities for work in science are on a much more generous scale than at Oxford.

Research in Social Studies

THE Vice-Chancellor also spoke encouragingly of the scheme for research in social studies at Oxford made possible by the five-year grant from the Rockefeller Foundation which has now been in operation for a year. An institute of statistics has been started, several research lecturers have been appointed, and promising schemes of combined research in Colonial Government, in politics, in social services, and in economics have been begun. The first year of the experiment has been a great success. Research activity in other humane studies is also increasing remarkably. Since 1931 the number of those working for research degrees in the humane faculties has risen from 145 to 256.

Rhodes Memorial Lectures: Dr. E. Hubble

THE Rhodes Memorial Lectures at Oxford will be delivered during the Michaelmas Term by Dr. Edwin Hubble, of the Mount Wilson Observatory. They will be given at 5 p.m. on October 29, November 12 and November 26 in the Milner Hall of Rhodes House, Oxford. The lectures will bear the general title of "The Observational Approach to Cosmology", and will deal in turn with the observational characteristics of that region of the universe accessible to telescopes now in operation, secondly with empirical tests of the physical nature of the spectroscopic 'red-shift', and finally in the third lecture with the possible models of the universe which follow from the previously established interpretation of 'red-shift'. Dr. Hubble, who is himself a former Rhodes scholar, is well known in England. As a result of his discovery of Cepheid variables in the extra galactic nebulæ, and his determination of their periods, nebulæ such as those in Andromeda were first definitely revealed as systems of stars comparable in dimensions with the huge galactic system of which our sun is a part. Working out from the nearer of these objects, and using his own determinations of their apparent luminosities, Hubble was enabled by statistical methods to find the distances of these objects in a volume of space of 300 million light years radius; from these distances and the velocity determinations of Slipher and Humason, he first established in 1929 the existence of a linear relation between distance and velocity (assuming the observed spectroscopic 'red-shift' to be due to Doppler effect).

HUBBLE'S law, it need scarcely be added, is basic to all discussions of the expanding universe, whether in the relativistic form of Lemaître, Eddington and de Sitter, or in the kinematic form of Milne. As clearly set out in his Halley Lecture at Oxford in 1934, Hubble himself, however, has been led to seek whether there do not exist observational methods of determining whether this 'red-shift' is due to a velocity of recession, or to some other, as yet unspecified, physical cause. There will, therefore, be a widespread interest in his Rhodes Memorial Lectures, not only because they will reveal the conclusions which he has reached in this matter, but also because they may be expected to show the results of the furthermost exploration of the universe which can be carried out with the existing instrumental equipment.

Radcliffe Travelling Fellowship in Astronomy

THE Board of Visitors of the University Observatory, Oxford, is inviting applications for the Radcliffe travelling fellowship in astronomy. This new fellowship in observational astrophysics, open to all suitably qualified astronomers irrespective of nationality, carries an annual salary not in excess of £700, the exact amount of which is fixed by the Board. The fellow will divide his time approximately equally between the new Radcliffe Observatory in Pretoria with its 74-inch reflecting telescope, and the University Observatory, Oxford, with its new solar equipment, and will work on problems of his own choosing in observational astrophysics. The tenure of the fellowship is normally three years, but this period may be extended (or shortened) if this seems desirable in the case of a successful candidate. The fellowship therefore represents a stage in restoring the balance between observational and theoretical astronomy in England, now overweighted in favour of the latter, and at the same time marks the beginning of a new period of friendly and close collaboration between the two observatories concerned. The fellowship is being financed by the Radcliffe trustees, as an earnest of their interest in the study of astronomy in Oxford, while the nomination to and the emoluments of the fellowship are in the hands of the University.

The Harvard Tercentenary Celebrations

ELSEWHERE in this issue (p. 667) we print an account of the impressive functions by which the tercentenary of the foundation of Harvard University at Cambridge, Massachusetts, was celebrated as an outstanding event in the history of knowledge by a great gathering representative of all branches of learning and drawn from all parts of the world. A tribute of a different character came from six of the industrial leaders of the United States, in the form of a letter to President Conant directing attention to the indebtedness of American industry to the universities. They pointed to the large and increasing number of university trained men in industry and business as evidence of the influence of university education on industrial progress, and stated that, having caught the spirit of research from the universities, industry has applied its methods successfully and with noteworthy results. During the past twenty-five years, the number of industrial research laboratories in the United States has grown from a handful to more than 1500, and is rapidly increasing. "From the universities also flows much of the basic knowledge of science on which modern technical industry has built and will build in the future." The letter is signed by Walter S. Gifford, president of the American Telephone and Telegraph Company ; Alfred P. Sloan, jun., president of the General Motors Corporation ; Thomas G. Watson, president of the International Business Machines Corporation ; Pierre S. du Pont, chairman of the board of E. I. du Pont de Nemours and Company ; Owen D. Young, chairman of the board of the General Electric Company; and Walter C. Teagle, president of the Standard Oil Company of New Jersey. It is a striking tribute to the significance of university institutions in industrial progress.

African Problems

A wide and varied field was covered in the discussions which engaged the attention of the twenty-third biennial session of the International Colonial Institute held in London on October 6–8. As Mr. Ormsby-Gore pointed out in a speech at the banquet at which the delegates were entertained by the British Government, the Colonial Powers are all confronted with a number of problems, human, political and social, which have to be studied objectively in common. To this end the mere interchange of views and experience is useful, even though no very decisive conclusion may appear to emerge. In this respect, the pooling of experience and discussion of methods of meeting the new problems raised by the introduction of newspapers, broadcasting and the cinema are highly instructive. This, too, is perhaps the most beneficial outcome it is legitimate to expect from the discussion of the detribalized native, which was opened by Lord Lugard and occupied a considerable part of the session. It was evident, as might have been anticipated, that measures applicable to one area may not be possible in another. Thus the conclusion put forward by Father Charles, that tribalism can be revived successfully only under rule on tribal lines and by the use of native courts, may be accepted as a general proposition. Clearly, however, it cannot meet transitional cases, such as those to which Mr. Ormsby-Gore referred, when he spoke of the product emerging under missionary influence, for example, in the towns of the west coast, which it is difficult to fit into the evolution and progress of tribal life and the social organism. On the other hand, Prof. Basil Williams, while expressing approval of the system in the Belgian Congo, under which the mine-workers are encouraged to bring their wives, admitted that it has been impressed upon him that such a system would not be practical on the Rand, where mine-workers number a quarter of a million.

Natural Resources Conservation

One of the important questions discussed at the recent World Power Conference was the conservation of natural resources. Science Service, of Washington, D.C., has issued reports of papers, dealing with this subject, which formed the basis of a discussion at the Conference. It is stated that whether the business systems are capitalist or socialist or a combination of the two, we must organize our activities to meet the demands of natural law, and all civilized nations are struggling towards this end each in its own way. The principles laid down for 'resource planning' by the writer of the reports are to keep soil, water, forest and grass as at present, but to economize by every possible means in the use of irreplaceable minerals. Nature lays down the terms, and we must either obey or suffer. We can come to terms with Nature in regard to the self-renewing resources by using them only as fast as they are replaced. With regard to the non-replaceable minerals, we can come to terms only by finding new and abundant substitutes faster than we use up the older materials. It is a race between technology and waste. Face to face with the inexorable demands of Nature, we suffer from human weakness. The consent of the people has to be obtained in spite of the propaganda issued by those whose interests are opposed to the public welfare. The laws of a federal union of sovereign States are a tangle of inconsistent rights and powers that hampers the action of the nation. The United States are now struggling to acquire legal and political powers commensurate with their necessities. If it fails, we are threatened by a crisis when essential materials are exhausted and it becomes necessary to reduce the population.

British Chemical Manufacturers

Reporting on its activities during the year ended May 31, 1936, the Association of British Chemical Manufacturers justly claims to have rendered substantial assistance to an industry which is one of our most important national assets. It is concerned with the organization of displays of British goods, such as that provided by the British Industries Fair, with legislation and the incidence of taxation, with commercial treaties with foreign countries, with the Ottawa agreements and means for stimulating trade within the Empire, with transport, safety precautions, and in fact with any problem relating to the industry other than questions involving wages, hours and conditions of work. There is, however, much still to be done, and the Association is anxious to realize that expansion of services which would be rendered possible by an increase in its membership to include every chemical manufacturer in Great Britain. In his speech at the annual general meeting held on October 8, the chairman referred to the successful outcome of many of the enterprises which the Association has undertaken in the interests of its members, including in his survey a reference to the measures which are being undertaken to protect our factories against air attacks in the unfortunate event of war. The Association has also participated in investigations concerning the detection of toxic gases in industry. It is announced that the first pamphlet of the series, that dealing with hydrogen sulphide, will shortly be published by the Department of Scientific and Industrial Research. Dr. E. F. Armstrong was re-elected president for the coming year.

The Velocity of Light

FROM time to time, Mr. M. E. J. Gheury de Bray has published in the columns of NATURE communications on this subject. He has now brought together the results of his investigations in an article published in *Isis* (25, 2; September 1936), entitled "The Velocity of Light: History of its Determination from 1849 to 1933". Reprints of the article have been prepared and can be obtained from Mr. Gheury de Bray, Imperial Patent Service, First Avenue House, High Holborn, W.C.1 (price 1*s*.).

Pavlov Institute of Aviation Medicine

As successful flying over long distances or to high altitudes depends not only on the efficiency of the aeroplane and the skill of the pilot but also to some extent on such minor details as the clothing and diet of the pilot, the structure of the cabin, etc., an Institute of Aviation Medicine dedicated to Prof. I. P. Pavlov was organized about a year ago in Soviet Russia. The laboratories of the Institute make tests of clothing, oxygen apparatus and anti-noise helmets, and study the problem of producing light, warm and comfortable clothing for airmen. Oxygen apparatus used in flights is produced under the direct supervision of the Institute, and the fitness of airmen wishing to ascend to high altitudes is tested in the Institute's barometric chamber.

Early Photographic Instruments

SOME of the earliest instruments in the history of photography have just been acquired by the Science Museum, South Kensington, on loan from the Royal Photographic Society of Great Britain. They include three instruments used by Fox Talbot, the inventor of the first paper photographic process: (1) A camera lucida, the use of which on the shores of Lake Como in 1833 first suggested to him that the invention of a sensitive paper would record such scenes more perfectly than sketches made by hand. This is the instrument mentioned in his "Pencil of Nature", published in 1844. (2) Fox Talbot's solar microscope, with which the earliest photomicrographs on paper were produced. (3) A Culpepper type microscope, *c*. 1820. With other instruments and specimens which have recently been acquired and are in course of classification prior to exhibition, the representation of Fox Talbot's work in photography bids fair to be complete.

"Annual Tables of Constants and Numerical Data"

THE publication of the "Annual Tables" having lagged behind schedule since vol. 10 (1930), the new managing committee (Institut de Chemie, 11 Rue Pierre Curie, Paris, 5^{e}) proposes to make up for it by publishing the data for 1931–36 in a more condensed form and more critically edited, in separate fascicules by subjects, partly separately for 1931–34 and 1935–36 and partly for the whole period 1931–36. The set of these fascicules will form vols. 11 and 12 of the "Annual Tables". This programme is to be completed in 1937: the numerical material published in the "Annual Tables" will then be brought up to date. In addition, an index volume by substances for vols. 6–10 (1923–30), like that published for vols. 1–5 (1910–22), is to appear towards the end of this year. A new index volume by substances will be prepared for vols. 11 and 12, to be published in 1937. The Committee would welcome inquiries about the "Tables", and state that the back numbers have now been greatly reduced in price. The new fascicules are being issued at a very modest price, which will place them at the disposal of all scientific workers likely to need them in their investigations. The preparation of the "Annual Tables", which is a purely scientific and non-profit-making undertaking, is a worthy task deserving the active support of men of science in securing their prompt publication.

Dr. A. H. Mackenzie

IN announcing the death of Dr. A. H. Mackenzie, in NATURE of October 10, he was described, following "Who's Who", as "Pro-Vice-Chancellor of the Osmania University, Hyderabad". Prof. M. S. Ahmed writes to say that the correct official title is "Pro-Vice-Chancellor of and Special Propagandist for the Osmania University of Hyderabad". He adds: "Dr. Mackenzie was appointed to the position of Pro-Vice-Chancellor of the Osmania University in which capacity he had to work six months in the year at Hyderabad, and the remaining six months he had to spend in Great Britain in doing special propaganda in the British Universities on behalf of the Osmania University".

A Nova in Sagittarius

THE discovery of a nova on October 6 (the third to be discovered since last June) has been announced by telegram from the International Astronomical Union's Bureau at Copenhagen. The position is given as R.A. $18^{h}\ 4{\cdot}5^{m}$: Dec. 34° 21′ south: magnitude 6 on Oct. $6^{d}\ 0^{h}$ U.T. This position places the nova in the constellation of Sagittarius and roughly midway between the 3rd magnitude stars, γ Sagittarii and η Sagittarii. The discoverer is Mr. C. Jackson, of the Union Observatory, Johannesburg, who less than a month ago discovered a faint comet (1936 c). Owing to its southern declination of −34°, it will not be possible to observe the nova from the latitude of Greenwich, and further news of its behaviour must be awaited from southern observatories.

Announcements

The Royal Society of New Zealand has awarded the T. K. Sidey Summer-Time Memorial Medal and Prize for 1936 to Sir Leonard Hill. This award, which consists of a gold medal and £100 in New Zealand currency, is made to the person who in the opinion of the Council of the Society has made a valuable contribution to human knowledge by original research into the effect of light and solar radiations on human comfort.

The Huxley Memorial Lecture of the Royal Anthropological Institute will be delivered in the rooms of the Royal Society on October 27 by Prof. E. Westermarck, who will take as his subject "Methods in Social Anthropology".

The following appointments and promotions in the Colonial Service have been made: H. M. James, to be agricultural superintendent, Cyprus; C. H. F. Walker, to be agricultural officer, Nigeria; J. M. Waterson, to be plant pathologist, Agricultural Department, Bermuda; C. J. Taylor, to be assistant conservator of forests, Gold Coast; J. A. Allan, to be lecturer in botany, chemistry and physics, Department of Science and Agriculture, Barbados; L. P. Henderson (late agricultural officer), to be agricultural officer, Nigeria; Capt. J. R. Mackie (assistant director of agriculture), to be director of agriculture, Nigeria; F. B. Notley (entomologist, Kenya), to be entomologist, Agricultural Department, Tanganyika; D. F. Chesters (senior assistant conservator of forests), to be conservator of forests, Nigeria; Dr. J. C. Tull (Government pathologist and professor of pathology, Straits Settlements), to be pathologist, Cyprus; S. G. Willimott (Government analyst, Cyprus), to be assistant Government analyst, Straits Settlements.

The Institute of Hygiene of Czechoslovakia is carrying out important studies in connexion with vitamins in the diet of the poor, especially in winter, when most of their food contains only a very small quantity of antiscorbutic principles.

The central administration of the perfumery and cosmetics industry of the U.S.S.R. is to open an Institute of Cosmetics and Hygiene at Moscow in November. The Institute will consist of three departments devoted respectively to cosmetics, physiotherapy and plastic-therapeutic gymnastics, with a staff of specialists in dermatology and physical therapy.

We are asked to state that the address of the publisher of "The Way to Happiness for Humanity" noticed in Nature of October 10 (p. 636) is 93 Braybrook Street, London, W.12.

Messrs. Willibald Keller, Hindenburgstr. 94, Leipzig, are issuing shortly a new edition of the classical work "Die Alpen im Eiszeitalter" by Albrecht Penck and Ed. Brückner. The new edition will contain an additional chapter in which Albrecht Penck has given a survey of the present development of knowledge of the glacial period and the progress since the publication of the first edition. The subscription price of the work, consisting of three volumes, is 66 gold marks until November 30.

Applications are invited for the following appointments, on or before the dates mentioned:

One resident engineer, two senior engineers and one junior engineer for airport construction—Secretary, Office of Public Works, Dublin (October 21).

An assistant engineer in the Ministry of Transport—Establishment Officer (October 21).

A records officer in the office of the Industrial Research Council of the Department of Industry and Commerce, I.F.S.—The Secretary, Civil Service Commission, 45 Upper O'Connell Street, Dublin, C.8 (October 22).

A junior assistant in the Department of Civil Engineering, Queen's University, Belfast—Prof. Hummel (October 23).

A teacher in engineering and an engineering workshop instructor at the Kenrick Technical College, West Bromwich—Director of Education (October 23).

A technical assistant (electrical, mechanical and civil engineering industries) for a War Department inspection establishment at Woolwich—Under-Secretary of State (C. 5), War Office, London, S.W.1 (October 24), quoting "Appts./1".

An assistant director of horticultural education and an agricultural advisory officer to the Norfolk County Council—The Clerk, The Shirehouse, Norwich (October 24).

Two assistant drainage engineers in the Ministry of Agriculture and Fisheries—Secretary (October 26).

A public analyst to the Metropolitan Borough of Chelsea—Town Clerk (October 29).

A professor of philosophy and a lecturer in the Department of Education and Philosophy, Canterbury University College, Christchurch, New Zealand—Secretary, Universities' Bureau, 88A Gower Street, London, W.C.1 (October 31).

A lecturer in the Department of Pathology, University, Birmingham—Secretary (October 31).

A head of the Science Department, West Ham Municipal College—Town Clerk and Education Officer, West Ham (November 6).

An assistant curator (male) at Somerset County Museum, Taunton Castle—The Curator.

A civil engineer for the Public Works Department, Government of North Borneo—Secretary, British North Borneo (Chartered) Company, Staple Hall, Stone House Court, Bishopsgate, London, E.C.3.

Civil engineering and architectural assistants in the Drawing Office, H.M. Dockyard, Portsmouth—Civil Engineer-in-Chief, marked "D.O. Assts., Portsmouth".

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 688.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Calculation of Structure Factors and Summations of Fourier Series in Crystal Analysis: Non-centrosymmetrical Projections

Two useful methods for carrying out these operations have recently been described in NATURE. The Fourier synthesis reduces to summing series of the type

$$\Sigma\Sigma A \cos h\theta_1 \cos k\theta_2 \text{ and } \Sigma\Sigma A \sin k\theta_1 \sin k\theta_2,$$

θ_1 and θ_2 being co-ordinates in a projection of the structure, expressed as fractions of the cell sides. In the method described by C. A. Beevers and H. Lipson[1], strips of numbers are printed giving all the values of $A \cos h\theta_1$ from $A = +99$ to $A = -99$, $h = 0$ to $h = 20$, and θ_1 at 6° intervals from 0° to 90°, the latter 15 numbers being printed in a row along the strip. The synthesis then reduces to selecting the correct strips, placing them over each other, and adding up the columns of numbers.

In the calculation of structure factors a similar summation is involved, but in this case θ_1 and θ_2 are the co-ordinates of the atoms in the unit cell, and the coefficients A depend upon their scattering power. In the method described by W. L. Bragg[2], contoured graphs of the function are prepared for different combinations of the indices h and k, from which component terms in the structure factor can be read off.

The object of this note is to point out that a numerical method which I described some time ago[3] for the summation of Fourier series can be applied equally well to the calculation of structure factors. The method is similar to that of Beevers and Lipson, but the strips of cosine factors are prepared for different values of A only, the different values of h being obtained by moving the strip along an appropriate scale, graduated in terms of θ_1, when the required result appears under a fixed column. The method may not be quite so fast as that of Beevers and Lipson, as the strips have to be moved along the scales for each successive value of θ_1, but this loss is partly balanced by the greater ease of selection of the strip, only 100 being required instead of about 4,000 in the method of Beevers and Lipson.

In order to use the method for the addition of structure factors, we note that the co-ordinate θ_1 now refers to the position of an atom in the unit cell, and may therefore have any value. If the given values are restricted to multiples of 6°, then there is a maximum possible error of 3° in assigning the position of the atom. This is not important if the value of the index h is 1, but for high values of the index the error is serious. This difficulty is overcome by extending the set of *scales* to cover all values of θ_1, from 0° to 180°, at one degree intervals (or half-degree intervals, if still greater accuracy is required). The same strips of cosine factors are used as before, with the same sorting board and fixed columns, but the new scales prevent the error of position of any atom ever exceeding the maximum of 3° no matter how high the index of the plane may be. Some examples of the new scales are shown in Fig. 1, from which their construction and use will be clear, on reference to the previous description[3]. The numbers are written on strips of cardboard with V ends, for easy attachment to the sorting board. The scales for $\theta = 6°$, 12°, 18°, etc., are identical with the scales for $h = 1, 2, 3$, etc., used for Fourier synthesis. For Fourier summations, the numbers on the scales represent successive values of the co-ordinate θ_1, in steps of

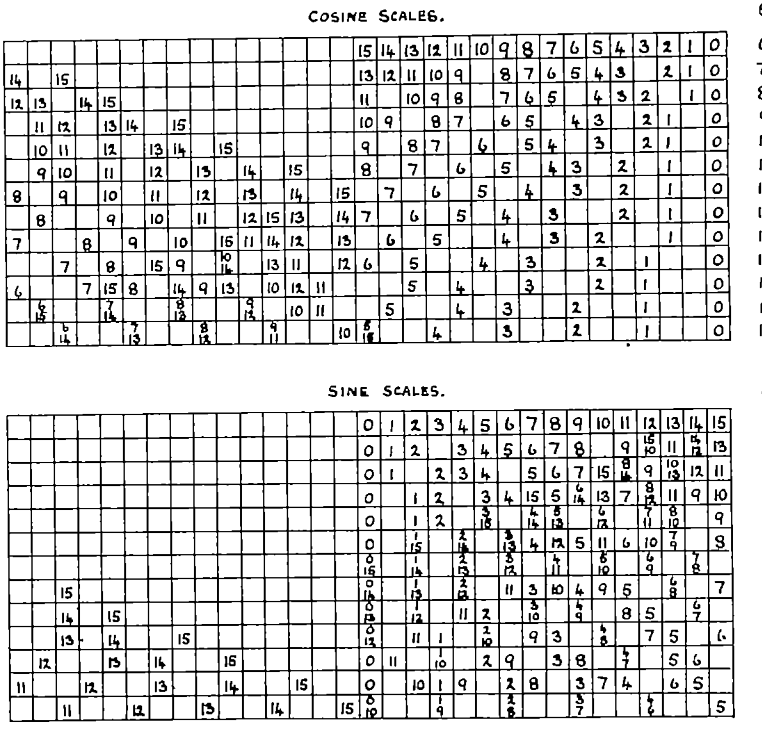

FIG. 1.

6°, and a separate scale is used for every different value of the index h. For structure factor summations, the numbers on the scales represent successive values of the index h, and a separate scale is used for every different value of the co-ordinate θ_1, the number of scales required being equal to the number of atoms in the asymmetric unit.

In practice, the calculation of a number of structure factors can be made with the same facility as the calculation of the electron density at the same number of points on a projection of the structure. The first factor, $A \cos h\theta_1$, is evaluated for a number of values of h, and these results are used as coefficients for the final summations. The method is particularly useful for structures containing large numbers of atoms of rather similar scattering power, such as occur in organic compounds, where sufficient accuracy can be obtained by using the same atomic f-curve for all the atoms, but weighting the coefficients in proportion to the atomic numbers.

As a further supplement to my previous paper[2], I should like to point out that the Fourier synthesis of non-centrosymmetrical projections can be carried out very easily either by my method or that of Beevers and Lipson if the arbitrary phase constant, α, is first combined with the measured F values. The series

$$\Sigma\Sigma\ F \cos (h\theta_1 + k\theta_2 - \alpha)$$

may be written

$$\Sigma\Sigma\ [(F' \cos h\theta_1 + F'' \sin h\theta_1) \cos k\theta_2 - (F' \sin h\theta_1 - F'' \cos h\theta_1) \sin k\theta_2]$$

where $F' = F \cos \alpha$ and $F'' = F \sin \alpha$.

Examples of such projections are given in a recent paper on the structure of resorcinol[4]. Further simplification of the formulæ often follows from relations between the phase constants in the different quadrants of the reciprocal lattice. These relations are summarized for the different space groups in a recent book by Dr. Lonsdale[5].

Self-Interaction of Neutrons and Protons

IT is known that, starting with Fermi's expression for the coupling between a heavy nuclear particle and the field of electrons and neutrinos, we get in the second approximation the law for interaction between proton and neutron[1]. This law:

$$\sim \frac{g^2}{hc} \frac{(h/mc)^{2s}}{r^{5+2s}}$$

(g is Fermi's constant, the best choice for s is 3) gives a divergent result at $r \to 0$, which shows the impossibility of constructing a point model of a heavy particle, just as the classical and quantum electrodynamics both lead to infinite self-interaction of a point charged particle on Coulomb's formula. The only reasonable method so far proposed to remove this difficulty of classical electrodynamics is the non-linear generalization of Maxwell's equations developed by Mie and Born[2], who introduced a new characteristic length (the analogue of the radius of the electron).

Fermi's theory also introduces a universal length $r_0 = \sqrt{g/hc} \sim 10^{-16}$ cm., or better $r_0 = \sqrt[s+2]{(h/mc)^s g/hc} \sim 10^{-13}$ cm. with $s = 3$, say, which fact changes the whole situation of the interaction problem, as well as that of the theory of scattering[3]. Let us compute the interaction between heavy particles transferred not only by a single pair, but by 2, 3 . . . n pairs of light particles, electrons and neutrinos. In electrodynamics this would correspond to the transfer of energy by 2, 3 . . . n photons, afterwards emitted and absorbed by two charged particles. Putting $\bar{\psi} = \psi_0 + \psi_1 + \ldots \psi_n$ for the wave function of two heavy particles, we get for the interaction, as far as the $2n$th approximation:

$$V = -\frac{g^2}{hc}\left(\frac{h}{mc}\right)^{2s} \frac{1}{r^{2s+5}} \sum_{n=0}^{\infty} (-1)^s \alpha^n \left(\frac{r_0}{r}\right)^{2n(2+s)}$$

where α_n are numerical coefficients of the order unity.

At great distances ($r \gg r_0$) we obtain, of course, the previous law, but at small distances $r < r_0$ the successive members of the series are of the same order of magnitude, which corresponds physically to the *intensive interaction transfer* not only by one pair but also *by many pairs of light particles*, or as we may say, by *showers* of particles.

Though at $r \to 0$ each member of the series tends to infinity, the whole sum can be finite, which is best illustrated by the example of the following expression, the expansion of which is quite similar to our series, differing from it possibly only in the values of numerical coefficients:

$$V = \frac{g^2}{hc}\left(\frac{h}{mc}\right)^{2s} \frac{1}{(r^{2s+4} + r_0^{2s+4})^{1+1/(2s+4)}}$$

As the exact values of the coefficients are at present not of great importance owing to the preliminary character of the whole of Fermi's theory, it is very attractive to admit this law as the general form of interaction, giving the required finite proper energy of a heavy particle Mc^2 at $r \to 0$, just as the potential of Born's non-linear theory leads to the finite value of mc^2 for the electron. We find in this manner that Fermi's r_0 plays the role of the radius of a heavy particle. We see that by taking into account the shower-like character of energy transfer, realized by many particles, or photons, we are led immediately to the non-linear law of interaction.

A New Kind of Ring Phenomenon in Sputtered Metallic Films

AN interesting ring phenomenon which is expected to throw light on the mechanism of condensation of sputtered particles was noticed while working on cathodic sputtering. Details will be published elsewhere.

It was noticed that if a small bead of plasticine or a small drop of oleic acid is placed on a specially cleaned (not degased) glass plate, and the plate given a deposit of cathodically sputtered silver or copper in air, a set of coloured rings is formed surrounding the bead or the drop. The distance between the successive sets of coloured rings increases with the distance of the ring from the centre. In monochromatic light the rings appear alternately dark and bright.

The drop of oleic acid does not spread on the glass until the discharge is started. Within a few minutes of the starting of the discharge the drop flattens into a white patch, which shows a grey deposit when observed under a magnifying eyepiece. The ring formation occurs around this patch.

A small bead of paraffin was also tried instead of plasticine. The paraffin melted and spread on starting the discharge, but no marked rings were obtained though colours could be seen, being usually blue in the centre with a wide yellow circular band round it.

The same experiment using a small piece of pure aluminium instead of the oil did not show any rings.

Some separate experiments showed that oleic acid does not spread to any appreciable extent when placed on either a freshly prepared or an old mirror made by a cathodically sputtered deposit even when heated up to 100° C.

The formation of the rings may be explained by assuming the condensed metallic sputtered particles to form a liquid expanded film or a gaseous film. The experiments of Ditchburn[1] on the surface motion of cathodically sputtered cadmium lends support to this view. The oleic acid spreads on this fluid film, and thus gives rise to the interference rings. It is quite likely that adsorption between the metal particles and the organic molecules also plays a part in the formation of the rings.

The spreading of the oleic acid drop into a patch may be explained by assuming the cohesive forces on the surface of the acid drop to be decreased by the adsorption of the metallic particles on the acid surface. Moreover, the surfaces in contact now are not glass-acid-air but metallic fluid-acid-air.

Surface of Copper formed by Solidification *in vacuo*

MECHANICAL or chemical treatment is usually required to prepare a surface for electron diffraction examination. This may lead to distortion of the structure which is undesirable, particularly when comparison with X-ray data is required. A surface formed by solidification of a molten metal *in vacuo* may be regarded as probably the most satisfactory obtainable. In the present investigation the purest available copper was melted in an alundum boat in a fused silica tube which was connected to a Hyvac pump. The surface of the specimens was bright and smooth. Both electron diffraction and X-ray photographs were taken. Both gave sharp spots indicating the presence of large crystals, but whereas X-rays showed that the orientation of the crystals differed from specimen to specimen, electron diffraction showed spots from copper crystals orientated with either {111} or {100} planes parallel with the surface, the {111} orientation being most frequent. Twenty photographs gave similar results.

We also examined specimens which had been maintained for a long time at 950° C. The results were identical. Even a single crystal acquired, after heating, a layer of crystals orientated with their {111} and {100} planes parallel with the surface, independent of the structure underneath. A silver specimen behaved similarly.

It would be necessary to examine a large number of metals of different structures before venturing to give an explanation of these results. It may be connected with surface tension, by which the planes of highest atomic density arrange themselves parallel with the surface. It is interesting to note[1] that the first layer of cuprous oxide formed on polycrystalline copper is orientated so that a [111] direction is perpendicular to the surface. In our experiments no trace of oxide was found and no distortion.

A New Electron Oscillator

A NEW arrangement of electrodes in a vacuum tube has enabled me to generate electron oscillations of higher intensity and with more ease than by the split-anode magnetron, with which I first succeeded in producing the intense micro-waves by connecting it in 'push-pull'.

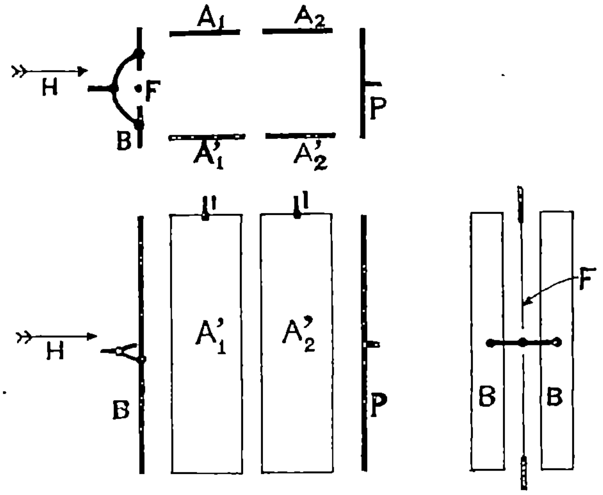

FIG. 1.

In Fig. 1, F is a straight filament cathode which is stretched in about the same plane as the plate-electrodes B. P is an end plate on the other side. Both B and P are kept at a low positive or negative potential.

A_1, A'_1, A_2, A'_2 are rectangular slab electrodes which are all kept at a high positive potential. A magnetic field is applied in the direction H. Now A_1 and A'_1 are connected together, and so are A_2 and A'_2. When a parallel wire circuit is connected to A_1 and A_2, a strong oscillation current is obtained in the circuit, the wave-length of which is determined simply by the circuit constants.

The adjustment is not at all critical, and the wave-length may be varied within a comparatively wide range about the value estimated as the simple oscillation of electrons between the two opposite plates B and P.

A large number of modifications and different combinations of electrodes are conceivable.

When the magnetic field is gradually increased, oscillation appears at a certain range and then stops, and reappears again at a higher field strength in some cases. If the magnetic field is inclined a certain number of degrees from the symmetrical axis of the arrangement, oscillations of much longer wave-lengths may be generated with the frequency as determined by the oscillation circuit.

The principle of operation of this oscillator may be considered either as the B–K oscillation with positive grids of novel construction and a magnetic field applied in order to straighten the paths of electrons, or as the split-anode magnetron oscillation when the electron stream is differently directed and the split-anodes assume accordingly different shapes. In order to distinguish these tubes of new principle, we are calling them 'Osaka tubes' in our laboratories.

The static characteristic shows no negative resistance effect, but it must naturally be understood that, under oscillation conditions, the negative resistance relation obtains dynamically, so that the electron oscillation may be maintained by the timely retroaction from the circuit.

A useful output of a few watts was easily obtained, when the input was about twenty watts and the wave-length was about eighty centimetres.

With the present tube, the micro-waves were successfully produced by connecting together A_1 and A_2 as well as A'_1 and A'_2, and also by connecting a parallel wire to A_1 and A'_1.

I wish to express my thanks to Prof. Yagi for his valuable suggestions.

Insect Coloration and Natural Selection

THE letter from Prof. E. W. MacBride in NATURE of August 29 (p. 365) escaped my attention while on holiday, and since my return I have not been able to find time to consider it until now.

The central point of the letter, dealing with the occurrence and inheritance of mutations, should be answered by more competent hands than mine, but certain points bearing more particularly on the work in which I am chiefly engaged require comments.

It is much to be regretted that so many critics of the theory of mimicry confine themselves to the phenomena as exhibited by butterflies. Let us disregard altogether the Lepidoptera, for the present; then the argument against mimicry so often stressed by my friend on *negative* evidence falls to the ground. For other orders of insects are attacked by birds and insectivorous mammals to a very high degree, and exhibit abundantly the phenomena of mimicry. Therefore the current explanation of mimicry cannot be set aside because in one particular group there is not considered to be sufficient evidence of attacks by enemies which could have a selective influence. Meanwhile, evidence of attacks by birds on butterflies continues to come to hand, and I would ask those who have not witnessed such attacks to consider again the striking evidence presented by Mr. T. H. E. Jackson[1].

Regarding the influence of environment, I directed attention in NATURE some years ago[2] to a well-known case of mimicry which refutes that argument: the Lycoid insects. But since the minutiæ of geographical variations are so often disregarded by critics, the following example of another difficulty is given. The ease with which minor variations can be studied on the large wings of butterflies is responsible for their use in illustrations: I have no doubt that analogous examples will be found among other orders when they have been studied to the same degree.

The female of the butterfly, *Papilio cynorta*, wherever it occurs in tropical Africa closely resembles superficially other butterflies having all the characters of aposematic species. On the west coast, it is like the female of the Acraeine *Bematistes* (= *Planema*) *epaea epaea*, both having a white pattern on a dark background: the male *epaea* has the paler parts of an orange brown. This species, like many others of the West African region, ranges eastwards into Uganda where it undergoes a change. The sexes are alike, the dark background becomes greyish-brown and the paler pattern cream coloured, the pale areas much reduced in size. This is the race *paragea*. The *Papilio* female (race *peculiaris*) undergoes a corresponding change in appearance: the male remains as in West Africa.

Both species extend into south-west Abyssinia and undergo further changes of importance for the argument. We find, as in Uganda, that both sexes of the *Bematistes* are alike but for a different reason: in Abyssinia the female has adopted the orange-brown coloration of the male, which is very little different from the western form: for this reason the Abyssinian race is named *homochroa*.

What happens to the *Papilio* in Abyssinia? According to the argument from environment, it also should respond to Abyssinian influences by becoming orange-brown. Incidentally, it may be remarked that, on this argument, the conditions in Abyssinia must be nearer to those of West Africa than are the conditions in Uganda: a conclusion which I feel sure would not be admitted by geographers. The Abyssinian *Papilio cynorta*, discovered by Sir Arnold Hodson, does not follow the usual model: one may presume that it is because it does not possess the gene for the orange-brown colour. *P. cynorta arnoldi* is black and white, somewhat different in pattern from the western race mimicking *B. epaea epaea*, and resembling the Abyssinian race *aethiops* of the abundant Danaine *Amauris niavius*. The highly interesting fact is that in West Africa the Danaine model is present for the *Papilio* to mimic, but the latter has, so to speak, found it easier to approach the Acraeine *Bematistes*. But when the *Bematistes* adopts in Abyssinia a garb impossible for the *Papilio* to assume, the latter has recourse to an appearance which is within its power, by slight modification of its western form: this latter, however, is supposed to be the result of West African conditions.

Finally, no account is taken, by the advocates of environmental causation, of the highly significant fact that, in complete accordance with the demands of natural selection, mimetic resemblances are superficial. Mimicry deceives the artist but not the anatomist. Moreover the details of the likeness between model and mimic are not the same. It is a commonplace that apparently the same effect may be produced by different means, a fact also in accord with natural selection.

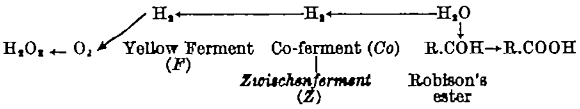
Keilin's Cytochrome *c* and the Respiratory Mechanism of Warburg and Christian

ACCORDING to the investigations of O. Warburg and his co-workers[1] on the reaction



the yellow ferment (F) acts as a more or less specific dehydrogenator of the di-hydro-co-ferment ($Co\mathrm{H}_2$), which cannot be oxidized either by molecular oxygen, or by methylene blue. The *cozymase* reacts in a manner analogous to the co-ferment (H. v. Euler and co-workers[2]).

Until now it has been uncertain whether the direct re-oxidation of the leuco-form of the yellow ferment ($F\mathrm{H}_2$) by molecular oxygen really takes place to any considerable extent in the living tissue cells, where the oxygen pressure is often very low, and whether the $F\mathrm{H}_2$ possibly could be re-oxidized by other substances in the cells, for example the cytochromes.

I have recently investigated the kinetic relations between oxygen, cytochrome *c* and the yellow ferment. The experiments were performed in the following manner: Co, Z, HCN, $m/50$ $NaHCO_3$ and in certain cases F were mixed in a glass cell of 1 cm. thickness to the volume of 3 ml. Z was used in such small amounts that the oxidation velocity of Robison's ester was proportional to the quantity of Z. After ten minutes the solution was saturated with nitrogen or oxygen or mixtures of both, and then a small quantity of oxidized cytochrome *c* ($\mathrm{Fe}^{\cdots}\mathrm{OH}$; pure, from beef heart[3]) was added. The pH of the solution was 7·35. The light absorption at 550 mμ was determined photo-electrically. Now the substrate, the potassium salt of pure Robison's ester, was added and the light absorption at 550 mμ was followed.

A priori, three different reactions would be expected to be possible:

$$\begin{aligned} O_2 + F\mathrm{H}_2 &= H_2O_2 + F \quad \ldots\ldots\ (1)\\ 2\mathrm{Fe}^{\cdots}\mathrm{OH} + F\mathrm{H}_2 &= 2\mathrm{Fe}^{\cdot\cdot} + F + 2H_2O \ \ldots\ (2)\\ 2\mathrm{Fe}^{\cdots}\mathrm{OH} + Co\mathrm{H}_2 &= 2\mathrm{Fe}^{\cdot\cdot} + Co + 2H_2O \ \ldots\ (3)\end{aligned}$$

The experiments proved that reaction 3 does not take place. Thus cytochrome *c*, like oxygen and methylene blue, is unable to oxidize the di-hydro-co-ferment directly.

Reaction 2, on the contrary, takes place most rapidly. If molecular oxygen and oxidized cytochrome *c* were both present in the solution, the relative velocities of reactions 1 and 2 were dependent on the oxygen pressure, but within wide limits independent of the concentration of oxidized cytochrome. The accompanying table shows the relation between the oxygen pressure and the relative reaction velocities at 22° C.

Oxygen pressure (mm.)	Per cent $F\mathrm{H}_2$ oxidized by oxygen	Per cent $F\mathrm{H}_2$ oxidized by cytochrome *c*
760	69	31
150	54	46
38	20	80
0	0	100

About the same values for an oxygen pressure of 150 mm. were found at 31° C.

In the living tissue cells, the average oxygen pressure is much lower than 38 mm. *Thus the re-oxidation of the yellow ferment by cytochrome seems to be the physiological method* occurring in cells containing the Warburg-Keilin iron-porphyrin system—that is, nearly all known cells. It should be pointed out that nothing is said above about another problem, namely, how much of the total cell respiration takes place by means of the yellow ferment.

An Effect of X-Radiation on the Blood

IN the treatment of malignant disease by X-rays or radiation, a highly important question is that of dosage. So far as we are aware, there is no simple method of determining quantitatively, even only approximately, the effect of a given dose except by observation of the effect on the irradiated tumour.

It is well known that irradiation produces marked changes in the blood, but no systematic examination of the cause of these changes during a prolonged course of treatment appears to have been made. We have undertaken therefore to investigate whether such irradiation produces a measurable change in some definite constituent of the blood, so that there may be a check on the effect of the radiation administered. By a new and accurate photo-electric method of estimating the total (and also the acid-soluble) phosphorus in the red cells, plasma, serum and whole blood of the patient under treatment, we have been able to ascertain, by taking measurements before and after irradiation by X-rays or radium, that the ratio of the whole phosphorus in the red cells to that in the plasma (a ratio which is usually high in the case of cancer patients but of the order of 5 or less in that of other patients) is reduced, even after only one treatment, by so much as 50 per cent in extreme cases, so that the phosphorus-partition falls within the normal range.

Our results indicate that it may be possible to judge of the effect of X-ray dosages by measuring changes in the phosphorus partition in the red cells and the plasma. As an example the following two cases may be considered, in which the figures given denote milligrams of phosphorus per 100 c.c.

	Whole blood	Red cells	Plasma	$\frac{\text{P in cells}}{\text{P in plasma}}$
Case I (before irradiation)	25·5	53·0	6·0	8·8
(after ,,)	38·75	69·0	14·5	4·8
Case II (before ,,)	22·5	49·0	4·5	11·0
(after ,,)	20·0	54·0	8·75	6·8

These figures were obtained for blood taken from the patients when fasting. The results of the phosphorus partition in the blood elements of a large number of patients will be published in a later communication. It seems to us that a periodic examination of the blood along these lines during a course of treatment may be a valuable guide to the changes in the condition of the patient.

This work has been done under the auspices of the Cancer Research Committee of the University of Sydney.

Formation of Carbon Dendrites

THE formation of long carbon dendrites in the electrolytic reduction of aqueous colloidal dispersions of graphitic acid was recently reported by Luke, Madgin and Riley[1].

If instead of the slightly viscous solution, a micellar solution of high viscosity[2] is employed, this phenomenon is also shown clearly, as the movement of the colloidal particles away from the cathode towards the anode is hindered. In the near future a detailed description of other experimental results will be published.

It has been found possible to transform a colloidal solution of graphitic acid into a transparent gel which contains much water and is very similar to the gel of gelatine. The movement of the lamellæ of graphitic acid under an electrical potential is still further hindered in the gel. On touching a small piece of the gel with two platinum electrodes at a potential difference of 220 volts, carbon is formed by reduction at the cathode before the relatively large lamellæ have time to move away. The orientation of the disordered lamellæ under the influence of an electrical field observed under the microscope in polarized light[3] is confirmed by Messrs. Luke, Madgin and Riley[1].

The electrochemical reduction of graphitic acid makes possible the following experiment. A thin film of graphitic acid[4] moistened with a few drops of water can be transformed into a thin film of graphite. It is possible to write on a film of graphitic acid, which may be formed on a piece of paper, using a platinum electrode.

Points from Foregoing Letters

A RAPID numerical method for the calculation of structure factors and the summation of Fourier series in crystal analysis, which is also applicable to non-centro-symmetrical structures, is described by Dr. J. Monteath Robertson.

The interaction between two heavy nuclear particles is computed by Dr. D. Iwanenko and A. Sokolow on Fermi's theory, assuming the interaction transfer, not by one alone, but by an arbitrary number of pairs of electrons and neutrinos. The generalization of the previous law obtained gives the finite self-energy of a proton or neutron, just as Born's non-linear theory leads to finite self-energy of a point charge, which was impossible on the usual Coulomb formula.

The formation of coloured rings when silver or copper is 'cathodically sputtered' upon a glass plate, on which a drop of oleic acid has been placed, is described by U. K. Bose. The author explains the phenomenon by assuming that the condensed metallic sputtered particles form a surface film of the 'liquid expanded' or 'gaseous' type.

Surfaces of copper crystallized from a molten state by cooling *in vacuo* have been investigated by S. Dobinski and Dr. C. F. Elam both by means of X-rays and by the electron diffraction method. X-rays showed that the orientation of the crystals differed from specimen to specimen, while the electron method showed spots from copper crystals preferentially arranged. The authors suggest that this arrangement may be due to the planes of highest atomic density, (111) and (100), arranging themselves parallel with the surface.

Diagrams illustrating a new arrangement of electrodes in a vacuum tube, by means of which electron oscillations of higher intensity than those obtained with the split-anode magnetron can be produced, are submitted by Prof. K. Okabe. A useful output of a few watts was obtained with an input of about twenty watts. The wave-length was eighty centimetres, but may be varied within a comparatively wide range.

Further evidence in support of the view that natural selection rather than environmental conditions determines mimicry in insects is adduced by Prof. G. D. Hale Carpenter.

Experiments with several constituents involved in the mechanism of respiration of cells, carried out by H. Theorell, show that citochrome *c* (a pigment found in muscle tissue, etc.) is unable to oxidize the di-hydro-co-ferment directly, but does oxidize the leuco-form of the 'yellow pigment'.

The ratio of the phosphorus content of red cells and the plasma of the blood is found by Dr. H. L. Brose and E. B. Jones to be changed after treatment with X-rays or radium. The authors give two examples and suggest that the change may possibly serve as a measure of the effect produced upon the patient by a given dose of X-rays or radium.

Further experiments illustrating the reduction of graphitic acid at a cathode and the formation of carbon dendrites are described by Dr. H. Thiele.

Research Items

Brain Size in Man and the Great Apes

Dr. Franz Weidenreich, who has succeeded the late Dr. Davidson Black as honorary director of the Cenozoic Research Laboratory of the Geological Survey of China, has made the endocranial cast of Peking man the basis of a comparative study of the size of the brain in man and the great apes (*Palaeontologica Sinica*, Ser. D, 7, 4). To the two casts of the original skull and the reconstructed specimen, he has now added a third from a composite reconstruction by himself from material freed from the matrix recently. He points out that previous studies have dealt with the relief of the casts, but the material now available makes it possible to deal more generally with shape and proportions and to show the direction of development. The first feature to strike the observer is the small size of the brain of *Sinanthropus*, even when allowance is made for the fact that the first skull is that of an immature individual. Taking the three together, the cubic capacity may be put at approximately 1,000 c.c., as against 900 c.c. for *Pithecanthropus* and 1,450 c.c. for modern man (male) and 1,300 c.c. (female). Among the anthropoids the gorilla is not quite 600 c.c. and the chimpanzee below 500 c.c. The general average of modern man is below that of Neanderthal man, which works out at 1,425 c.c., so that it would appear that the hominids reached the maximum of skull capacity in that type, and in modern man it is on the decrease. A further point which emerges is that the size of the brain, especially in the hemispheres, increases almost equally in all directions during the development of the hominids, while relative as well as absolute increase is greater in the direction of height, next of length and least of breadth. *Sinanthropus*, *Pithecanthropus*, the Neanderthal group and recent man represent different stages in human evolution which are well marked off one from another.

White Rats and Lamarckism

The experiments of McDougall, in which he trained rats to discriminate between the light and dark exits from a water tank by giving them a tetanizing electric shock when they chose the lighted exit, are well known. He claimed that the effect was inherited, so that after some generations the descendants of rats which had been trained in every generation learned much more quickly than untrained controls. He neglected, however, to record pedigrees or to keep the individual records of every animal. His work has now been repeated by Prof. F. A. E. Crew (*J. Genetics*, 33, No. 1) using more critical genetical methods. With 18 generations of rats, 1,445 trained and 1,014 controls, the average number of errors in the trained stock did not decrease, and showed no difference whatever from the control stock. Analysis of the pedigrees shows, however, that genetic factors are heavily concerned in determining the scores, quickness to learn being a general dominant to slowness. The parent-offspring correlation for learning was 0·3. A 'quick' strain was developed by selection. Preliminary experiments with each rat, in which the light was constant at both exits and no shock was administered, showed that many rats chose regularly the right or left hand exit and others were photophobic. The genetic basis of these conditions is being further investigated, but the claim for a Lamarckian effect is found to be without foundation.

Imaginal Buds of the Appendages in *Drosophila*

Dr. Charlotte Auerbach has recently traced the development of the imaginal buds of the legs, wings and halteres in *Drosophila* from the first larval instar onwards (*Trans. Roy. Soc. Edinburgh*, 57, 787 ; 1935). The basis of the work is genetical, and the problem as to how the mutant genes influence the development of organs and parts cannot be properly answered unless the normal growth of the parts is known. The account given of the formation of the thoracic appendages and their connexions with associated organs is exceptionally complete. This is followed by a preliminary description of the development of certain mutant wing-types. The time in development when such mutants deviate from typical growth is recorded and the deviation followed in some detail. In wing-development there are four recognizable periods of morphogenetic significance, and various external factors, operating at definite periods, induce the manifestation of certain mutants. The paper is very fully illustrated, and forms a useful contribution to the subject concerned.

The Genus *Keramosphaera* Brady

In December 1935, Mr. E. Heron-Allen read a paper before the Royal Microscopical Society upon this mysterious genus of Foraminifera, lost sight of for forty years, in which he compared it with other almost legendary organisms, such as the flying squirrel (*Eupataurus*) of Kashmir ; the emu-like bird *Pesophax* ; and the water-rat (*Crossomys*), which was found by Monckton in British Guiana in 1906 and has never been seen or heard of since. Beyond the two original specimens of *Keramosphaera* sent home by Brady in 1874, it was never seen again until 1914 and 1931, when single specimens were recorded from the Antarctic by Pearcey and Wiesner. The original Brady specimens were lost, until Mr. Heron-Allen re-discovered them during the assemblement and systematic rearrangement of the scattered collections of Foraminifera at the Natural History Museum. Thus encouraged, he re-examined the Brady (*Challenger*) material and brought three more specimens of *Keramosphaera* to light. These are illustrated in his paper recently published in the *Journal of the Royal Microscopical Society* (56, 113 ; June 1936). Between the reading and the publication of this paper, two further specimens of *Keramosphaera* were recorded by Mr. A. Earland from some *Scotia* material, which was worked upon, described and illustrated by F. Pearcey many years ago. In his paper, Mr. Heron-Allen directs attention to a partially lost and wholly unpublished paper by his late friend, F. W. Millett, who died in 1915. This paper he found during the sorting, so far as was possible, of the mass of papers and material left behind by Millett on his death in 1915. It deals with the shore sands of Misaki, Japan, and though it was evidently begun and abandoned in 1904, it contains a fortunately full and complete description, with two drawings, of a further species of the genus *Keramosphaera*, to which Millett gave the name *K. densa*. His two beautiful drawings are reproduced in the paper under notice, together with Miss Barbara Hopkins's drawings of the newly discovered specimens, but the type-specimens of *K. densa* have totally disappeared, though Mr. Heron-Allen discovered an empty and damaged slide, which had contained them, among the debris left behind by Millett.

The Trisomic Mutations of *Œnothera Lamarckiana*

Œnothera Lamarckiana is known to have a ring of twelve chromosomes and one free pair. Dr. D. G. Catcheside (*J. Genetics*, 33, No. 1) has determined the various possible primary trisomic mutations which can arise through non-disjunction in these conditions. Thirteen dimorphic forms such as *lata* (giving *Lamarckiana* and *lata* when selfed) will arise from simple non-disjunction. It is shown that double non-disjunction on the same side will produce trisomics which breed true and are therefore called monomorphic. These will number 48 and fall into four categories according to the number of chromosomes between the two non-disjunctions in the ring of twelve chromosomes. A further twelve monomorphic trisomics, called by de Vries 'accessories', correspond with each of the twelve dimorphic trisomics, having an extra chromosome from the ring, thus making a total of 73. The dimorphic trisomics will segregate a monomorphic-I trisomic when selfed, provided it is viable. The latter, pollinated by *O. Lamarckiana*, should produce *Lamarckiana*, the monomorphic and the dimorphic trisomic from which it was derived. This analysis of the possible types of trisomics is confirmed in various cases by the genetical and cytological behaviour of known trisomics, such as *lata*, *albida*, *scintillans*, *oblonga* and *cana*. The whole constitutes a valuable analysis of the possibilities in this type of cytological change.

A New Disease of Mushroom Beds

A SHORT note by Mr. P. H. Williams (*Gard. Chron.*, Aug. 22, 1936) announces the discovery in Britain of a new fungal competitor of the mushroom, previously known only in the United States and Denmark. A truffle, *Pseudobalsamia microspora*, has been found in the casing soil of experimental mushroom beds at the Cheshunt Research Station, and though it does not appear to attack the mushroom themselves, it is a rather serious menace by virtue of its energetic competition for food. This discovery strengthens the plea for sterilizing all casing soil before addition to a mushroom bed.

Solar Temperature

A RECENT article by Messrs. W. W. Coblentz and R. Stair (*Bur. Standards J. Research*, July) sums up the results of their measurements of the energy in the ultra-violet of the solar spectrum within and outside the earth's atmosphere, and the conclusions to be drawn from them. Their measurements are made by means of a standard radio tube and a photoelectric cell, coupled in such a way that, when the cell is illuminated, an audio signal is produced the frequency of which is diminished to one or two per second as the illumination is reduced to zero. The wave-length of the light is restricted by suitable filters, and the tube is coupled to a radio transmitter the frequency of which it modulates. The arrangement is attached to a sounding balloon and sent aloft, and from the signals received from the balloon at different altitudes, the distribution of energy between wavelengths 2900 and 3400 tenth-metres outside the earth's atmosphere is calculated. The graphs show that this distribution is most nearly represented by that of a black body at 4,000° K., and that it is incorrect to assume that solar radiation is identical with that of a black body at 6,000° K.

Invertase and Dyestuffs

J. H. QUASTEL and E. D. Yates have extended their study of the action of dyestuffs on enzymes to invertase acting on sucrose (*Enzymologia*, 1, 60; 1936). The enzyme is inactivated by both acid and basic dyestuffs, though not all are toxic. It is considered that the basic dyes combine reversibly with an anion of the enzyme, the compound being catalytically inactive, whereas acid dyes combine with the cation. Sucrose competes with both classes of dyestuffs for the enzyme. Glucose competes with basic dyestuffs to a greater extent than with acid dyestuffs for the enzyme, whereas with fructose the reverse is the case. The results cited have led the authors to regard invertase to be acting as a *zwitterion* the oppositely charged groups of which are bridged by sucrose: the glucose section is attached to the anion and the fructose moiety to the cation of the enzyme. Such a theory, however plausible in terms of ionic nomenclature, disregards the effect of stereochemical changes in the sugar molecule in rendering invertase inoperative.

Photographing Meteor Trails

IN *L'Astronomie* of May there is an interesting article entitled "Détermination du Radiant de l'Essaim des Étoiles Filantes du 9 Octobre 1933", by S. Arend and G. Camille Flammarion. It describes the results of photographing 25 meteors between $20^{h}\ 03^{m}$ and $20^{h}\ 55^{m}$ at the Observatory of Juvisy. An objective 12·5 cm. in diameter and with focal length 60 cm. was used, and α Lyræ was utilized as the star for guiding purposes. Of 25 recorded trails only 8 were retained, the remainder being either very short or extremely faint. The equations of the great circles for these eight trails were used, and the method of least squares applied to determine the radiant with the greatest accuracy. An interesting comparison is made between the results and those obtained on the same night at the Observatory of Uccle with an exposure of 38 minutes. The computed positions of the radiants were almost exactly the same, at $\alpha = 262{\cdot}29°$, $\delta = 53{\cdot}74°$ (referred to the equinox of 1933.0), after making corrections for zenithal attraction and diurnal aberration. These photographic results gave a very accurate determination of the radiant of the Giacobinids on the night of October 9, and show that the radiant was well defined, not a diffuse area, whereas visual observations led to the conclusion that the radiant was diffuse, due to the observational errors which are almost impossible to eliminate in the usual visual work. This conclusion is very important in view of the fact that wherever meteor work is conducted now by competent observers, there is an increasing tendency to treat the results as provisional and approximate, pending more accurate methods of observation.

Some Properties of Aluminium and its Alloys

PARIS MEETING OF THE INSTITUTE OF METALS

AT the invitation of the Bureau International des Applications de l'Aluminium, the autumn meeting of the Institute of Metals was this year held in Paris, on September 14–19. As a natural consequence of this invitation, the majority of the papers presented for discussion at this meeting dealt with various aspects of the metallurgy of aluminium and its alloys.

CONDUCTIVITY OF ALUMINIUM

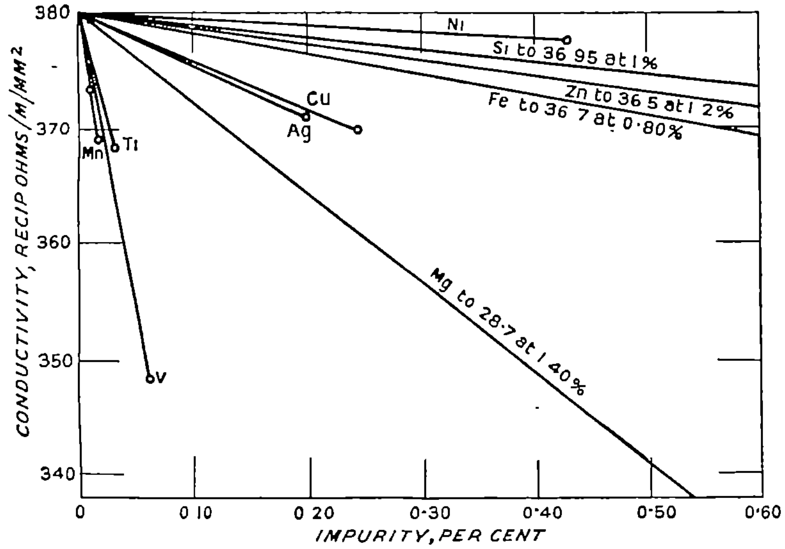

FIG. 1 Mean decrease of conductivity in alloys of aluminium as a function of the content of alloying element added.

The first paper presented, by M. Gaston Gauthier, dealt with the conductivity of super-purity aluminium and the influence of small metallic additions. The aluminium employed in the investigation exceeded 99·99 per cent purity, and the added elements were those which may occur as impurities in commercial aluminium. The high purity of the basis metal made it possible to determine accurately the effect of each one of the added elements in the almost complete absence of other impurities. The accompanying diagram (Fig. 1) summarizes the results; it shows the average decrease of conductivity brought about by the various elements within the limits investigated. It is possible to divide the elements into three groups:

(1) Gold, gallium, nickel, silicon, iron and zinc, all of which have little effect.

(2) Copper, silver and magnesium, which have rather more effect.

(3) Titanium, vanadium, manganese and chromium, all of which exert a considerable effect.

In spite of the precautions taken in preparing his samples, the author's figures do not support Norbury's law, to the effect that the increase in resistivity brought about by the addition of the same number of atoms is larger, the greater the separation between the added element and the basis metal in the periodic system. M. Gauthier is considering whether another generalization cannot be established.

INDIRECT FACTORS

Between the initial development of a light alloy and its general utilization in industry there is usually encountered a number of unsuspected and troublesome factors. The Marquis de Fleury, assisted by Dr. H. Portier, presented an analytical study of these factors and the laws governing them in the course of a paper entitled "The Complex Interdependence of the Properties of Alloys and the Industrial Conditions of their Manufacture, Testing and Use". Factors which are apparently unrelated are shown to be actually so interdependent that a simple modification of one can upset the equilibrium of the whole cycle of the life of a casting. This interdependence has been studied in the particular case of aluminium alloys, although the problem is, of course, the same for all metals. Metallurgists are warned against the unconsidered application of new alloys, and engineers against hasty condemnation of the materials with which they are supplied. In spite of careful forethought, unsuitable applications will be encountered which will throw a prematurely advertised material into disfavour; this is the explanation, according to the authors, of the amazing setbacks to be remembered in the history of the most logical developments.

PROPERTIES AFTER PROLONGED HEATING

An investigation of the strength of pure aluminium and various aluminium alloys after heating for long periods at 75°–300° C. was described by Prof. A. von Zeerleder and Dr. R. Irmann. The strength properties of these materials were also determined in the state of complete stabilization. The heating periods employed extended over approximately two years. After treatments of different duration at elevated temperatures, some specimens were cooled and tested at room temperature, others being tested at the treatment temperature. For complete softening at 250° C., for example (that is, to obtain the properties observed in completely stabilized samples), heating periods of at least six months are required in the case of pure aluminium and Anticorodal, and of more than two years for Avional and 'Y' alloy. A still longer heating time is necessary in the case of the alloy 'R.R. 59'. To determine the decrease in strength of any material after heating for long periods at elevated temperatures it is necessary, therefore, to carry out tests of long duration.

The values of the yield-point observed in the normal short time test after heating periods of one year form a basis for calculations for engineers. The permissible loads can be ascertained only by observation of the creep limit, and this property is being studied by the authors.

ALUMINIUM REFLECTORS

It is well known that the power to reflect incident light is possessed by various metal surfaces to a very varying degree even when such surfaces have been reduced to the same condition so far as possible by grinding, polishing, etc. Not only does the reflectivity vary over the visible range taken as a whole, but it also varies for different wave-lengths and not always in the same manner. The reflectivity of a silver mirror, for example, is very high when measured on the longer waves, but decreases to almost vanishing point over a narrow band in the ultra-violet. In a paper presented by Mr. N. D. Pullen, a description is given of a dual anodic process designed for the treatment of aluminium surfaces in order to produce a high degree of reflectivity. The first bath, in which the electrolytic brightening is produced, is a mixture of sodium carbonate and sodium phosphate in the approximate proportions of 3 : 1 having a strongly alkaline reaction. The second bath, in which a reinforcing film is produced, consists preferably of a strong solution of acid sodium sulphate. Data are given showing the reflectivity of aluminium surfaces treated by this method compared with a standard silver mirror and other surfaces such as chromium plate, nickel plate, etc.

THE FUNDAMENTALS OF FORGING

All metallurgists are familiar with Prof. Portevin's methods of treating the practical problems of industry in a fundamental manner. The complex properties of castability and weldability have been greatly elucidated by his publications in the past, and now, together with his colleague Dr. Paul Bastien, he has applied the same method of treatment to the study of forgeability. In their paper, "Study of the Forgeability of Various Light and Ultra-Light Alloys", the authors have endeavoured to determine, by means of laboratory tests, the optimum conditions for hot-working. With this in view they have compared the results obtained from static bending and compression tests and dynamic bending and tensile tests. They have indicated the important part played by the rate of deformation, and have shown that the bending test appears to be the most convenient, speedy and sensitive. The tests were carried out on aluminium; on copper-aluminium alloys containing 6 and 12 per cent of copper; on aluminium-magnesium alloys containing 5, 10 and 15 per cent of magnesium; on magnesium; on magnesium-copper alloys containing 5, 10 and 15 per cent of copper; and on magnesium-aluminium alloys containing 3, 6 and 9 per cent of aluminium. The methods of testing employed have made it possible to define the capacity for hot-work of these various alloys.

International Quaternary Association

CONFERENCE IN VIENNA

THE Third Conference of the International Quaternary Association (INQUA.) was held in Vienna on September 1–8 under the patronage of Dr. Kurt von Schuschnigg, the Austrian Chancellor, and Dr. Hans Pernter, Minister of Education. Dr. Otto Ampferer, director of the Geologisches Bundesanstalt in Vienna, who is well known for his researches on the interglacial gravels of the Alps, presided over the Organization Committee, and Dr. Gustav Gotzinger was president of the meeting. To these latter and to the genial and multi-lingual secretary, Dr. Helmut Gams of the University of Innsbruck, the meeting owed its undoubted success. That the attendance far exceeded expectations may partly be ascribed to the opportunity of hearing the veteran Prof. Albrecht Penck, who acted as honorary president and spoke on most of the subjects discussed during the Congress.

The geographical situation of Vienna is ideal for such a conference, being accessible without undue travelling to most European nations. To those from the west, the opportunity of seeing a country which, during Quaternary times, took on the character of a pronounced steppe, was a great temptation, and the thick loess deposits of the Austrian Weinviertel north of the Danube came in for much attention. Here in both fossil and recent examples it was possible to study two of the climatically controlled soil types which the researches of Russian scientific investigators have recently brought into prominence, namely, the black-earth or *chernozem* which margins the steppes, and the brown-earth or forest soil of the better-watered areas. This utilization of the physical character and colour of the soil to interpret the climatic conditions under which it was formed is a novelty to glacialists from the leached podsol areas of the north-west, and seems to afford a subtle and useful criterion of changing climate. The main fossil soil zone of the Austrian sections lying between the Younger and Older Loess is locally dated by archæological finds of Aurignacian type just above it, and is therefore presumably of interglacial or Riss-Wurm age, the loess being glacial. These sections were ably demonstrated by Dr. Gőtzinger, who, with others, wrote a descriptive guide book for the Congress.

During the visit to Krems, a halt was made at Spitz in order to be present at the unveiling of the memorial to Josef Beyer, the celebrated Austrian archæologist. On a subsequent visit to Eggenburg, Beyer's collections were inspected in the museum, and those who visited this town will long remember the hospitality of its inhabitants. An excursion in the Austrian Alps on September 9–23 was largely attended and enabled the participators to see the terraces and moraines of the quaternary glaciers and a number of interglacial deposits, including the famous Höttıng breccia.

The difficulties of language were keenly felt by many members of the Congress. Most of the papers were delivered in German, but, one understands, not always in German as spoken north of the Danube. Many were read from manuscript at undue length and at a speed which made them unintelligible to foreigners. It is surely possible to find some cure for this. Much would be gained if authors would make a point of reading their papers in abridged form in some language other than their own. This procedure, which enables preparation to be made, would not be much of a linguistic feat for most members of the Congress and would add greatly to the intelligibility of the proceedings.

There was a universally expressed desire on the part of the members to meet in England at some future date in order to see the classic sections of East Anglia and Yorkshire.

Contributions of Chemistry to Pharmacy and Medicine

THE Hanbury Gold Medal of the Pharmaceutical Society of Great Britain, which is awarded for "high excellence in the prosecution or promotion of original research in the Chemistry and Natural History of Drugs", was presented to Dr. F. Pyman at the opening of the School of Pharmacy on October 7.

Dr. Pyman afterwards delivered the inaugural sessional address, in which he reviewed the contribution made by chemistry to pharmacy and medicine during the twentieth century. He pointed out that whereas medicine has contented itself for many thousands of years with the use of drugs of animal, vegetable and mineral origin and of their simple extracts, it is only within a comparatively short period of the world's history—barely 130 years—that the development of organic chemistry and other sciences has enabled these crude drugs and pharmaceutical preparations to be replaced in many instances by principles isolated from them in the form of pure chemical compounds. This tendency has been reflected in the diminution in the number of crude drugs and galenical preparations included in successive British Pharmacopœias. This isolation of the pure active principles of drugs has been of importance not only as an end in itself, but also as a means of giving the organic chemist opportunities of working on the constitution of these compounds both analytically and synthetically.

Expense may prevent the widespread substitution of the synthesized product for that obtained from natural sources but, Dr. Pyman noted, the improvement in the methods for the production of tropinone by Robinson is at least one example of a laboratory synthesis which has brought the time appreciably nearer when both atropine and cocaine may be commercially available as synthetic products. The extraction of chemical constituents of vegetable drugs has stimulated the search by biochemists for the active principle of biological products. Raw liver taken by sufferers from pernicious anæmia over long periods caused nausea, and many patients were unable to continue the treatment. The work of Cohn led to the introduction of a method by which the activity present in the original liver could be concentrated in a fraction which represented about one thirtieth of the original bulk, while further work has enabled still more concentrated preparations to be made. Attempts to effect still further concentration and to isolate the active principle are making slow progress, firstly owing to the instability of the active principle and secondly to the fact that there is no satisfactory animal test for its efficiency in pernicious anæmia.

The consideration of these researches led Dr. Pyman to review the development of chemotherapy, research in which postulates co-operation between chemist and biologist. It is a commentary upon the difficulties in this field of research that the pioneer work of Ehrlich and Bertheim in 1907 still remains the outstanding example of the application of chemotherapeutic principles. That the laboratory worker will steadily add to the products available for the physician is certain, and there is no doubt that in many directions laboratory products will produce results not otherwise attainable. Nevertheless, the isolation of an active principle does not mean the death of the original vegetable or biological product. Tincture of nux vomica, tincture of digitalis or extract of ergot will have their place in medicine and may well produce physiological effects which cannot be obtained by their isolated active principles.

Educational Topics and Events

Cambridge.—The Central Committee for Agricultural Research Organizations has appointed H. Hunter, of St. Catharine's College, to be director of the Plant Breeding Institute in succession to Sir R. H. Biffen.

The director of the Solar Physics Observatory has made the following appointments: W. Moss, to be first senior observer, J. C. Dobbie, of Trinity College, to be second senior observer, E. G. Williams, of Trinity College, to be first junior observer.

Oxford.—Dr. H. M. N. H. Irving, of Queen's College, has been appointed tutor in natural science at St. Edmund Hall—a new appointment.

Mr. Alec Naylor Dakin, formerly Lady Elizabeth Hastings Scholar of Queen's College, has been elected to the Lady Wallis Budge Fellowship in Egyptology at University College. Mr. Dakin was educated at Heath School, Halifax, and was placed in the first class in Classical Honour Moderations and in the second class in the Final Honour School of *Literæ Humaniores*.

The Right Hon. W. G. A. Ormsby-Gore has been elected to an honorary fellowship at New College. Mr. Ormsby-Gore's work when Under-Secretary of State for the Colonies in a former administration, as well as his archæological writings, which have achieved a wide success, and his work in the preservation of ancient monuments while acting as Chief Commissioner of His Majesty's Office of Works, thus receive well-deserved academic recognition.

Sheffield.—The following appointments have been made: Dr. R. Rado, to be assistant lecturer in mathematics; Mr. T. L. Morgan, to be assistant lecturer in civil engineering; Dr. W. A. Kirkby, to be lecturer in fuel technology.

THE formal opening of the thirty-fifth session of the Sir John Cass Technical Institute took place on the evening of October 6, when an address was delivered by Bishop Paget to those assembled in the Great Hall, which forms a part of the recently erected extension of the Institute. The chairman of the Governors, the Rev. J. F. Marr, who presided, remarked that during the past two sessions, in which the additional accommodation provided by the extension has been in use, the volume of work has increased 15 per cent. This continued expansion is creating a new demand for additional laboratory accommodation for chemistry and biology, and also for lecture rooms for chemistry and physics capable of seating more than 70 students. The policy of fostering research has been followed consistently throughout the history of the Institute and during the past session 35 students were engaged in this type of work. In discussing the financial help which the Institute has received, Mr. Marr referred particularly to the generous support of several of the important oil companies in connexion with the courses in petroleum technology. New developments of the present session include advanced courses in botany of final degree standard and post-graduate courses in biochemistry and chemical engineering. An extension of the course in bacteriology will give additional facilities for post-graduate work. The Principal, Mr. Geo. Patchin, said that, of the 62 students successful at London post-matriculation examinations, 1 obtained the degree of Ph.D., 10 the degree of M.Sc., 5 the B.Sc. degree with first class honours, 6 the B.Sc. degree with second class honours, 15 the pass degree and 1 the B.Sc. Engineering (Metallurgy) degree with first class honours.

Science News a Century Ago

Caroline Herschel and Sir John Herschel

ON October 20, 1836, Caroline Herschel, then eighty-six years of age, wrote from Hanover to Sir John Herschel at the Cape. In the course of her letter she said: "I have four complete years of the 'Astronom. Nachrichten' ready bound for you. . . . I wished to give you the number of the paper (but cannot find it again) where Bessel speaks of Saturn's satellites, but my eyes are so dim and I am too unwell for doing anything. I will therefore only say he has seen the 6th but not the 7th, the ring being in the way. In No. 293 two of Bessel's assistants, Beer and Mädler, say a great deal about the observations of your father, but that goes for nothing. I will only say in general that he did in one season more than any one else could have done, and would have resumed the *hunt* the next fifteen years if nothing had interfered. And the Georgium Sidus was followed as long as anything could be obtained from that planet, and it will yet be some twenty years before he will be in that favourable situation in the ecliptic where he was at the time the satellites were discovered. . . ."

Warwickshire Natural History and Archæological Society

ACCORDING to the *Analyst* (5, 303), the first quarterly meeting of the members of the above society was held at Warwick on October 22, 1826, Sir H. Dryden, Bart., being in the chair. After some preliminary remarks by the chairman, the gathering was addressed by Dean Buckland, who is reported as saying that "the walls of Warwick Castle, the walls of the town, and the walls of the cathedral, were composed of strata till recently unknown to geologists. He saw them twenty years ago, but he did not know what was their composition, but still in his travels he had borne in mind the remains of the animals contained in the strata, in the hope that the time might come when the darkness in which these fragments were eclipsed would be dissipated; and when he should be able to make some important discovery to the scientific world. It was a matter of gratification to him that within the last two hours that darkness *had* dissipated; and he was now able to say that in Warwick—under their feet—and on Guys'-cliff there were the remains of many extinct species and genera of animals, whose names were as yet unuttered in England. . . . He ventured to say with as much confidence as if endowed with the spirit of prophecy, for he knew from geological inspection, and from example added to example, that under this town, Leamington and the surrounding neighbourhood, were the remains of thousands of Elephants, of Rhinoceroses, of Tigers, of Buffaloes, and a variety of other animals which he could enumerate."

Ehrenberg's Microscopical Discoveries

IN its column of "Miscellanea", the *Athenæum* of October 22, 1836, said: "M. Alexandre Brongniart writes from Berlin that a discovery has been made by M. Ehrenberg of a very interesting nature. It is, that the homogeneous rocks, which are not very hard, but friable, easily split, entirely composed of silex, and known under the name of Tripoli, or the Polierschiefer of Werner, are entirely composed of perfectly recognizable skeletons of infusory animals, of the family Bacillaria. . . . These remains having perfectly retained their forms, the siliceous carcases of these infusoriæ are to be seen very clearly in the microscope, and may be easily compared to the living animals as observed and delineated by M. Ehrenberg. In many instances there are no appreciable differences. The species are determined by the form, and more surely by the number of chambers or transversal lines which divide these minute bodies. M. Ehrenberg has been able to count them, by aid of the microscope, and has recognized the same number of divisions in the living and the fossil species."

Spontaneous Combustion

THE *Medico-Chirurgical Review* of October 1836 gives the following account of a case of spontaneous combustion reported in the French Press to have taken place at Aunay in the Department of Avalon: "A very fat woman, aged 74 years, addicted to drinking brandy at 27 degrees, lived alone, and one evening returned home as usual, but, as she did not appear among her neighbours the next morning, they knocked at her door. No answer being returned to repeated demands, they summoned the mayor, who forced the door and exposed a horrible spectacle, accompanied by an extraordinary smell. Near the chimney lay a heap of something burnt to cinders, at the end of which was a head, a neck, the upper part of a body, and one arm. At the other end were some of the lower parts, and one leg still retaining a very clean shoe and stocking. No other traces of fire were to be seen, except a blue flame which played along the surface of a long train of grease, or serous liquor, which had been produced by combustion of the body. The mayor found it impossible to extinguish this flame, and summoned all the authorities; and, from the state of the apartment and comparison of circumstances, it was concluded among them that previous to going to bed, for which she had evidently been making preparations, the woman had been trying to ignite some embers with her breath. The fire communicating with the body by means of the breath, combustion probably took place, and would appear to confirm an opinion entertained by several learned men, that that which is called spontaneous combustion of the human frame never takes place without the presence of some ignited body near the person predisposed to combustion."

Societies and Academies

Paris

Academy of Sciences, September 21 (*C.R.*, 203, 549–572).

Jacques de Lapparent: The generating media of montmorillonite and of sepiolite. Deposits of montmorillonite should be classed as pyroclastic rocks, arising from the devitrification of a magnesian glass. Sepiolite can be produced under analogous conditions.

Douchan Avsec: The experimental verification of the fact, predicted by Lord Rayleigh's theory, of the existence of the stable preconvective regime and on the mechanism of the appearance of convective currents in a gaseous layer, heated uniformly from below.

Roger Tournay: The existence of zinc metaborate. The author has been unable to obtain the zinc metaborate, ZnB_2O_4, of De Carli. The devitrification of the equimolecular mixture always gives two layers, one of which is formed by the borate $2B_2O_3,3ZnO$.

Marcel Prettre: The influence of a chemically inert gas on the velocity of the chain reaction of mixtures of normal pentane and oxygen. Study of the influence of the addition of nitrogen on the oxidation and inflammation between 250° C. and 350° C. of mixtures of normal pentane and oxygen.

Pierre Trunel: The electric moments of some fatty diamines.

André Vialard-Goudou: The oxidation of some organic substances by perchloric acid. From the experiments described it is concluded that the attack of organic materials by perchloric acid is due to the direct action of the acid itself and not to that of its decomposition products.

Joseph Biechler: The organic tricyanomelamines and their relations with the polymerized dicyanimides.

Raymond Guillemet: The aphis of wheat and the effect of their attacks.

Copenhagen

Royal Danish Academy of Sciences and Letters, January 24.

Niels Bohr: Properties and constitution of atomic nuclei. The fundamental discoveries of recent years regarding the transmutation of atomic nuclei, have exhibited the extraordinary facility with which nuclei react with each other as soon as direct contact is established. This circumstance may be brought into intimate connexion with the general properties of nuclei, when it discloses a characteristic difference between the problems of the ordinary atomic constitution and the structure of nuclei.

February 7.

L. S. Fridericia: Influence of a vitamin deficiency on the rate of growth of the incisors of rats.

February 21.

Harald Bohr: A theorem concerning stable motions in the plane.

Elis Stromgren: Ole Römer's meridian observations and the so-called Mayer formula for the correction of the observed time of transit for instrumental errors. Most of our knowledge of Ole Römer's work as a reformer of astronomy is derived from the work "Basis Astronomiæ", edited by Romer's pupil Peder Horrebow in 1735. During recent years, with the aid of Dr. Ræder, a series of chapters of this historically important work has been translated into Danish. These translations have been published in *Nordisk Astronomisk Tidsskrift* and partly also in German in *Die Sterne*. The work is being continued, and the next issue of the *Tidsskrift* will contain an exposition of the question of Romer's meridian observations and of the so-called Mayer formula, which, as has been previously proved by the aid of the Romerian "Adversaria" edited by the Royal Danish Academy, is in reality due to Ole Römer and not to Tobias Mayer.

March 6.

Øjvind Winge: Investigations on linkage in *Pisum*. An attempt is made to map the genes of *Pisum*, on the basis of crossing-experiments involving 17 genes, and the experiments of other investigators. In all, 37 genes are considered. They are provisionally arranged in eight linkage groups, while the chromosome number is only 7. The inheritance of seed weight has been studied. It is found probable that the genes for seed weight generally act upon the linear size of the seed (third root of its weight). Instances of dominance for high as well as for low seed size are also demonstrated. The genes I (yellow cotyledon) and *Pl* (dark hilum) show linkage to genes for seed size.

Knud Jessen: Some new archæological datings in Danish pollen diagrams. Some archæological finds from the passage grave period of the younger stone age and from the Celtic iron age on the Danish isles of Langeland and Als afford an opportunity of fixing the age partly of Zone VIII in the pollen diagrams and partly of a phase in the immigration history of the beech in the southern part of Denmark.

Tokyo

Imperial Academy, July 13 (*Proc.*, 12, 179–204).

T. Nakayama: Note on the sum and intersection of two ideals in an algebra.

M. Moriya: Division algebras over a $\mathfrak{p}$-ad manifold of an infinite algebraic manifold.

M Hasegawa: A statistical study of the type of diurnal variations of terrestrial magnetism on quiet days.

Y. Ōshima: Chemical studies on the tannin substance of Formosan tea leaves. Two crystalline catechins, an amorphous tannin and gallic acid have been isolated and their constitutions determined.

T. Yoshida: The reaction between ammonia and carbon dioxide. The reaction $2NH_3 + CO_2 = CO(NH_2)(ONH_4)$ proceeds only in the presence of water It is a consecutive reaction of the second order, involving the formation of the intermediate complex $NH_3.H_2O$, and has a negative temperature coefficient.

C. Moriya: Notes on the germicidal properties of the soil flat-worm *Rhabditis pellio* Schneider.

K. Kikuchi: A new species of *Diaptomus* from Formosa.

S. Okuda: Description of a new non-motile polychæte, *Thoracophelia ezoensis* n.sp.

S. Hirayama: Germination of pollen obtained from mosaic tobacco plants. Mosaic virus is found to be without effect on the germination.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, October 19

UNIVERSITY OF LEEDS, at 5.30.—Prof. N. V. Sidgwick, F.R.S.: "Resonance in Organic Chemistry".*

Tuesday, October 20

EUGENICS SOCIETY (at the Linnean Society), at 5.15.—Eliot Slater: "The Inheritance of Mental Disorder".*

Thursday, October 22

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—H. T. Young: Presidential Address.

Friday, October 23

INSTITUTION OF MECHANICAL ENGINEERS, at 7.—Sir Nigel Gresley: Presidential Address.

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS, at 6.—Annual General Meeting. Prof. C. J. Hawkes: Presidential Address.

The Social Mission of Science

NOTHING has been more striking in the recent meetings of the British Association at Blackpool than the general indignation at the prostitution of the results of scientific inquiry for purposes of warfare, and the concern at the spread of political systems which reduce science itself and other of the richest elements in our intellectual heritage to servitude.

The opening address on cultural and social values of science (see NATURE, October 3, p. 594) with its emphatic repudiation of the inhumanity and insane misuse of science in the extension of aerial warfare to the destruction of cities and the killing and maiming of women and children by poison gas, incendiary bombs and high explosives, against which the only real defence is by retaliation, found echoes in the presidential address to Section G (Engineering) as in that of Prof. Philip to Section B (Chemistry). Sir Daniel Hall, speaking on science and social organization, uttered a grim warning that while of old every autocracy ended in a revolution, the chances of its successful overthrow in the face of guns and gas to-day are very different. Moreover, control by force is being reinforced by a subtler technique of subduing minds until the population is content to be slaves.

Prof. H. J. Fleure, in a further address on the science of man and the problems of to-day, urged the claims of science and intellectual freedom against aggressive and reactionary doctrines, nationalist and others, which are put forward to-day, and, like Dr. J. S. Huxley, strongly criticized the pretensions which attempt to erect fanatical racial hatred to the dignity of a science. Equally, Lord Horder emphasized the death which the totalitarian systems brought to the scientific spirit and the dangers which attend the sacrifice of individual freedom.

On many of the great issues of the modern world, the Blackpool meeting has made it plain where scientific workers in Great Britain stand. That they have not been unmindful of the responsibility to which the recent report of the University Grants Committee referred, is a hopeful sign; and it is well to remember that many of the addresses could scarcely have been delivered in some other European countries without disastrous consequences to the speakers. Even Sir Henry Dale's plea for support of tropical medical research more commensurate with our territorial responsibilities, for example, would almost certainly have been suppressed, in other circumstances, as detracting from the idea that the State can do no wrong.

It may be said, of course, that denunciation and demonstration are not enough, and in some of the speeches efforts were made to point out definite lines of advance. Scientific workers as such, however, can have no final power over policy, national or international; and without disparaging the need for practical proposals and definite organization, in which others besides scientific workers can participate, to prevent the infamous use of scientific work, it is well to remember that science has a spiritual message which her followers must give regardless of whether others heed its warnings or not.

This message of science also found welcome expression in discussions at the British Association meetings. The influence of science upon material progress and human comfort is much more commonly understood than its effect upon the human mind. To-day it is difficult to realize the liberation of life and intellect brought about by the works of Copernicus, Galileo and other pioneers of experimental philosophy. The principles of self-determination and self-government now accepted as democratic rights are indeed social effects of the independence of scientific inquiry involved in the new philosophy. The freedom of thought and action possessed by progressive peoples are direct consequences of the work of Galileo and other founders of experimental science.

Accordingly, it is well that scientific workers should take up the challenge which modern autocracies offer, not only to science itself but also to all that is best in man's heritage of culture. It is not for nothing that one after another of the speakers who followed Sir Richard Gregory in the discussion on cultural and social values of science deplored the decline of democracy and enlightened outlook. The whole discussion demonstrated the deep and wide respect still to be found for liberal culture, and the strength of the support which could be secured for positive action by a successful co-ordination of those connected with all cultural activities. In another discussion, on the strain of modern life, Lord Horder even more explicitly asserted his faith in the individual and in the enormous potentialities of the human spirit, maintaining that a rebirth of this spirit in British political life would be one of the best medicines our strained lives could have administered to them.

When individual freedom had been sacrificed, Lord Horder saw little chance of achieving the control through which alone he believed salvation could come to the human race. Chief among the remedies for the ill-effect of the strain of modern life he placed science, and especially science directed toward the study and development of the mind and spirit of men. So, too, Prof. Fleure pleaded for the scientific study of mankind as essential if society is to advance. Disregard of its teachings is one cause of the dislocation and disturbance which are baffling us all. Like Sir Daniel Hall, he also entered a fine plea for freedom of conscience and self-control in action on scientific grounds as the life-breath of policy and science. We cannot restrict scientific thought and imagination to defined spheres: sooner or later it must intrude everywhere.

The true aim of science is the enrichment of life, and the specific value of an education based on science is that it will encourage, if not create, a habit of acting on reason rather than emotion. Moreover, such an education could destroy the dangerous delusions which loyalties of party, country and religion are apt to foster, and teach people from their earliest years that men and women, however diverse as individuals, are collectively very much alike, and for this purpose a scientific education is more effective than a purely literary education. Science taught, not as an aid to a vocation but as part of the training of a modern citizen, may develop a habit of mind as ethical as that usually only associated with the study of what are called the humanities.

Apart from this, the cultural claims of science, as Prof. L. Hogben has pointed out, rest on the social fact that the use and measure of science intimately affects the everyday life of every citizen in a modern community. Education for citizenship, in fact, demands a knowledge of how science is misused, of the ways in which we fail to make the fullest use of science for our social well-being, and some vision of what human life could be if we planned our resources intelligently.

The cultural and spiritual claims of science need such emphasis if scientific workers are ever to make the full constructive contribution to the solution of the world problems of to-day which lies within their power. It is well, therefore, that such emphatic warnings should be uttered against the mass movements which now threaten the finest elements in the national life of almost every country. Without criticism the very life of society is stifled, and descent to the community of soldier and worker is rapid. Only as we can enlist the citizen in the constructive task of using wisely the new powers which science has placed at our disposal can we hope to preserve what is best in the world's heritage of culture, let alone to add to it.

This is the task of science in the education of the citizen. Before a new world-wide social order can be built up worthy of the limitless powers which the advance of science has put into the hands of men, the general community and its leaders must be persuaded that acquaintanceship with scientific forces is an essential condition of enlightened government. Without an adequate scientific background, it is impossible to evolve a social and political system in which progressive knowledge is used for the wisest and best purposes.

Even though some scientific workers may regard it as of little use to protest against the use of scientific knowledge in implements of war, they should not be unmindful of the necessity for science first to deliver her spiritual message regardless of whether it is heeded or not, and for her followers to seek to achieve the educational work which is an essential condition of transition to a better order. The misgivings expressed at Blackpool find support from such wide quarters as at Washington, in Mr. Cordell Hull's address to the delegates at the World Power Conference, in meetings of chemists at Bangalore, among scientific workers at the University of Cape Town, Cambridge and elsewhere; and they indicate that scientific workers are becoming ready to study these questions intensively, and either to develop an organization through which an effective common policy is possible or secure a re-orientation of existing organizations that would be equally effective. Nowhere is this feeling stronger than in Great Britain and the Dominions Overseas and in the United States of America, and the revived interest in the effect of science on society, as well as the quickened concern displayed at the British Association meetings at the use of science in the growing preparations for war, embolden the hope that a *rapprochement* for some such purpose as this between the British Association and the American Association for the Advancement of Science may not be impossible or impracticable.

The Rise of Man

Man makes Himself

By V. Gordon Childe. (The Library of Science and Culture.) Pp. xii+275. (London: Watts and Co., 1936.) 7*s*. 6*d*. net.

PROF. GORDON CHILDE has a sense of perspective in time, which has been developed to a degree exceptional even among archæologists, who juggle with millennia; and he is little more restricted in space, for he ranges from the north of Scotland to the Valley of the Indus with a familiarity which few may emulate. He is, therefore, in a position to recommend with confidence the study of archæology as an antidote to those modern pessimists, who are disposed to doubt the soundness of the foundations upon which the belief in 'progress', inherited from the late nineteenth century, takes its stand. Neither 'age', nor century, he argues, and equally no single area marked out by geographical or national limitations, can afford material adequate for such a judgment. The impartial inquirer must survey all time, and take the whole world as his province, before he ventures to pronounce upon the trend of events in present-day civilization.

However, even if the scope of inquiry in any estimate of modern development be extended to the broadest limits possible, the impartial point of view of a scientific investigator demands an objective standard by which 'progress' may be measured. As is well known, the judgment of the historian is apt to be coloured by his ideals—or prejudices; and essays in formulating an objective test, such as "an increased command over the material resources of Nature", are liable to be called into question. Prof. Childe offers as his objective standard the evolutionary principle of "survival of the fittest", which has the obvious merit that it links the study of man with biology and palæontology, and at the same time, as interpreted by him, bridges the awkward gap between physical and cultural, which has proved a stumbling block in much theorizing. Recognizing the ambiguity, or rather lack of content, in "the fittest", he interprets his criterion of progress as an increased capacity to enable members of the species to survive. In other words, the effect of any real advance in human development, physical or cultural, is shown in a consequent increase in population, as in the sharp rise in the population curve characteristic of the years which followed the Industrial Revolution of the early nineteenth century.

In the demonstration of the content of 'progress' which follows as a necessary corollary to his test of advance in the development of man, Prof. Childe shows that prehistory affords evidence of the occurrence of a succession of revolutions comparable to the Industrial Revolution, and of no less importance in the history of civilization. Some, indeed, almost certainly must have produced more far-reaching consequences than anything of which we know in recorded history. Here he elaborates suggestions which he put forward recently in his presidential address to the Prehistoric Society. He then pointed out that while the divisions of prehistory, the Stone, Bronze and Iron Ages, have lost the general and absolute chronological significance once attached to them, and as dates must now be regarded as applying only within restricted areas and under definite limitations, they are still significant as indicating certain crucial economic changes, which affect the whole character of the civilization of the time. In "Man makes Himself", this conception is worked out in some detail. Prof. Childe shows how the domestication of animals and plants initiated the neolithic economy and the growth of the village community, while the introduction of metals necessitated an increased specialization in prehistoric industry and commercial intercourse, which paved the way for the growth of an urban civilization, and thus ultimately of the great national and imperial organizations of the Ancient East.

An outline of the argument which forms the thread of Prof. Childe's book does less than justice to his vivid interpretation of archæological evidence as a growth of civilization and a network of interrelated cultural developments. His incidental reflections are both inspiring and delectable. In this connexion may be mentioned a timely caveat against attributing ideas and concepts to prehistoric man, which cannot be inferred directly from the archæological evidence, but rest on the analogy of primitive peoples of like culture. Prof. Childe does not believe that the Australians, for example, stopped thinking for perhaps thousands of years. May it not be, however, that a people who had attained a state of stable equilibrium in material culture, as apparently had the Australian aborigines, had also attained the limit of development in idea in that environment at an equally early stage. There is evidence of such an early arrest among certain peoples of North America. The problem needs further examination. At present the evidence is too scant for final judgment; but Prof. Childe's warning is none the less valid.

In his more strictly professional work, Prof. Childe has shown himself a master of closely reasoned archæological argument. He now gives proof that he is equally at ease in exposition on a large scale and in general terms. His professional colleagues will find his book a brilliant and stimulating study, while to the layman it will serve as a lucid interpretation of an intricate subject-matter. With Prof. Childe as tutor, none could question the value of archæological studies as an academic discipline, or as a practical guide to an understanding of the course of events in the life and development of man.

History of Science and Mathematics

(1) The Study of the History of Science
By Dr. George Sarton. Pp. v+75.
(2) The Study of the History of Mathematics
By Dr. George Sarton. Pp. v+113.
(Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1936.) 1.50 dollars each.

THESE volumes represent the substance of two inaugural lectures, (1) on the establishment of a seminary of the History of Science at Harvard University, (2) preliminary to a course of lectures on the history of mathematics. Apart from appendixes, they cover 52 and 38 pages respectively. It is observed that the history of science as an independent subject is a comparatively new study, and that, although some historical efforts were made so early as the fourth century B.C. by Aristotle's pupil, Eudemus of Rhodes, and were continued by later Greeks, while there have come down to us from the Middle Ages and modern times a whole series of writings in Arabic, Latin and other languages which might be catalogued under the heading "History of Science", nevertheless the first scholar to conceive of that subject as an independent discipline was Auguste Comte (1798–1857), and the first scholar who deserves perhaps more than any other to be called the father of the study was Paul Tannery (1843–1904). Even Tannery could write, so late as 1904, that the history of science is "nothing but an individual conception", by which he meant that it was not yet represented by a series of standard works, constituting the tradition of a definite and independent subject.

Tannery may not have been acquainted with William Whewell's "History of the Inductive Sciences from the earliest to the present times" (3 vols., 1837). This was, however, a collection of special histories, vol. 1 dealing with Greek physics, Greek astronomy, medieval physics, and astronomy from Copernicus to Kepler; vol. 2 with the history of mechanics, physical astronomy, acoustics, optics, "thermotics" and "atmology"; vol. 3 with other branches of physics, chemistry, natural history, physiology, comparative anatomy, and geology; but these histories were not brought into relation with one another so as to constitute one picture illustrating "l'évolution de l'humanité", or the progress of mankind. At the present time, what is being aimed at is rather a complete history of 'scientific thought', with the histories of the particular sciences thrown in, as it were. So far, apparently only one modern and complete treatise of this kind exists: Friedrich Dannemann, "Die Naturwissenschaften in ihrer Entwicklung und in ihrem Zusammenhange" (4 vols., second edition, Leipzig, 1920–23). Others have been begun, two of which should be mentioned: Federigo Enriques and G. de Santillana, "Storia del pensiero scientifico", vol. 1, Milano, 1932, and "Histoire des sciences" by Pierre Brunet and Aldo Mieli (of the Académie Internationale d'histoire des Sciences), vol. 1, Paris, 1935. It is claimed that the latter work will be unique in its kind; the first volume contains 1224 pages and covers the whole of antiquity and the beginning of the Middle Ages [see NATURE, October 10, p. 630].

Dr. Sarton's volume on the study of the history of science discusses generally the nature of the qualifications required by the scholar who would write a competent history of science, and the alternative points of view from which it might be written, involving different arrangements of matter; he adds warnings as to the pitfalls of various kinds against which the writer must guard himself. For example, the date of a discovery may be different from that of its publication: it may have been communicated earlier by word of mouth to a society or a circle of friends; the date given in the colophon to an old printed book has occasionally been shown to be wrong; even the particulars as to date of death or age on tombstones have sometimes been found to be inaccurate; the historian must verify everything.

The historian of science must have some acquaintance with the whole field of advancing knowledge. "One of the most pernicious types of error to which a false or shaky knowledge of living science frequently leads is the reading of modern conceptions such as atomic ideas, energy, evolution, into ancient texts." To appreciate a scientific text fairly, it is not enough to know how much of it is true from our more advanced point of view; we must find out how much of it was considered true or would appear plausible at the time of its composition, what led up to it, what was its influence; in short, it must be placed "as exactly as possible within the complicated network of our traditions".

A difficulty arises as to the relative amount of space to be given to different periods. Dr. Sarton observes that the tendency with some scientific workers is to divide the past not into periods of equal length, but into periods of equal productivity. On that basis, "the ancient times and the Middle Ages are entirely sacrificed to our more immediate past, when the slow gestation of centuries and millenaries was suddenly followed by an amazing outburst of discoveries".

The difficulty in the allocation of space is illustrated by the case of mathematics. Cantor's great history of mathematics was in four large volumes approximately equal in size and extending to about 4,000 pages in all. The first volume covered the period from the beginnings to A.D. 1200, the second A.D. 1200–1668, the third A.D. 1668–1758, and the fourth (which had to be written by a group of specialists under Cantor's direction) A.D. 1759–99. The growth of mathematics during the nineteenth and twentieth centuries has been so enormous that a history on the same scale could scarcely be contemplated. The late Prof. Cajori calculated that a history of nineteenth century mathematics (alone) on that scale would need some fourteen or fifteen additional volumes. The remedy lies in an alteration of the scale. "As only a fraction of the ancient mathematical writings have escaped destruction, any fragment, however insignificant, is very valuable, while for modern mathematics our task must be, on the contrary, to eliminate the great majority of the available writings and consider only a few". A general history in reasonable compass is that of Gino Loria, "Storia delle matematiche", in three volumes (1929), the first of which covers the period up to the Renaissance, the second the sixteenth and seventeenth, and the third the eighteenth and nineteenth, centuries; the last volume contains a good general account of modern mathematics.

As a practicable way of diffusing a knowledge of the history of modern mathematics, Dr. Sarton suggests that it should be the duty of instructors teaching special subjects to explain their history. He illustrates this idea by the theory of elliptic functions. If the teacher, in tracing the development of the subject, introduced the main creators of it, Fagnano, Euler, Lagrange, Legendre, Gauss, Abel, Jacobi, Clebsch, Kronecker, Halphen, and if he did this part of his task well enough, his audience would become familiar with some of the leading mathematicians of the last century. Similarly with other subjects taught in the universities to advanced students.

The volumes before us conclude with classified bibliographies for the history of science and the history of mathematics respectively, covering 16 pages in the first case and 25 in the second, besides notices of the greatest mathematicians of the nineteenth and twentieth centuries to the number of 118, with references to the best available biographies, editions of their collected works and editions of their correspondence in each case. These appendixes should prove extraordinarily useful.

T. L. H.

Biography of Coffee

The Saga of Coffee:
the Biography of an Economic Product. By H. E. Jacob. Translated by Eden and Cedar Paul. Pp. 384 + 27 plates. (London: George Allen and Unwin, Ltd., 1935.) 15*s.* net.

COFFEE has had much to contend with since its use as a stimulant was first made known to the world, and this biography of coffee deals in a very readable way with its vicissitudes during the last four to five hundred years, and with its influence on the development of western civilization.

The author first conceived the idea of writing the economic history of this product after seeing the bonfires of coffee at Santos which have been inaugurated by the Brazilian Government to meet the menace of serious over-production. It has been stated that 600,000 bags of coffee are destroyed every month in this manner.

How coffee-drinking and coffee houses were objected to by religious, political and medical bodies, how they were opposed by the ordinary taverns and the interests of the wine and beer trades, and how they were taxed for revenue purposes make fascinating reading. So also does the influence of coffee-production on colonial expansion in the tropics by the Western nations—the Netherlands in the East Indies, France in the West Indies, Portugal in Brazil, and, later, Great Britain in Ceylon.

The author, writing of the competition of tea and its popularity in Britain, makes a serious error in attributing this to the British conquests in India in the early part of the eighteenth century. No tea was produced in India until a century later, and only then were attempts made to grow it there because the East India Company feared trouble in China, which was the only source of supply. The first tea from India was sent to Great Britain in about 1840. At the period mentioned by the author the Dutch held the monopoly for spices and coffee in the East, and the British—who were there only as traders—were forced to bestow their attention on other commodities, of which tea from China was one of the most important.

Emulsions: Theory and Practice

The Theory of Emulsions and their Technical Treatment
By Dr. William Clayton. Third edition. Pp. ix + 458. (London: J. and A. Churchill, Ltd., 1935.) 25*s.*

DR. CLAYTON'S book on "Emulsions" has been transformed completely since the first edition was issued in 1923. Indeed, an inspection of the references shows that a very large proportion of the contents of the present volume is of later date than the second edition issued in 1928. The present volume may therefore be considered in most of its aspects as if it were a new publication.

The earlier chapters are naturally devoted to the fundamental principles of surface-phenomena, including air-liquid and liquid-liquid interfaces, which play so large a part in the production and stabilization of emulsions. Since water-in-oil emulsions are not formed, and stable emulsions of pure oil-in-water are limited to particles of the order of 10^{-6} cm. and to a maximum concentration of 1 in 10,000, the formation of emulsions depends on the presence of an emulsifying agent. These were formerly hydrophilic colloid such as gelatine; but in more recent years sulphates and sulphonates and sulphinates of known structure, and bases such as triethanolamine, $N(CH_2.CH_2.OH)_3$, have been used extensively.

Properties and theories of emulsions occupy two considerable and well-illustrated chapters, in which the recently defined property of 'thixotropy' plays an appropriate part; and inversion of phases is discussed in a chapter on dual emulsions. The problem of emulsification forms the subject of two chapters, concluding with a substantial section on the important process of 'homogenizing' milk and cream; but the converse process of de-emulsification is discussed in a separate chapter in which the majority of the references are of recent date, and an appendix is devoted to the separation of technical emulsions, with special reference to crude oil-field emulsions.

The practical character of the book is maintained throughout the new edition and is one of its most valuable features. Thus whipped cream is discussed in Chapter ii, and churning and separated milk in Chapter xii, whilst the whole of Chapter viii is devoted to biological investigations of milk, etc. Chapter ix is similarly devoted to miscellaneous emulsions, including emulsified bitumen as a road dressing, emulsified oils and fats as leather dressings, margarine and salad dressings as edible emulsions, with brief references to the delustring of rayon, the sizing of paper, and the preparation of agricultural sprays.

Author and subject indexes are provided, but the latter fails to guide the reader to clear definitions of terms such as cybotaxis, dineric interface and thixotropy, which may be cited as cases where it would be of real value to quote the first usage of names which are relatively new in the literature. The new edition is of obvious merit and is likely to prove indispensable even to those who already possess one of the earlier issues.

Animal Life in the Forth Area

A Vertebrate Fauna of Forth
By Leonora Jeffrey Rintoul and Evelyn V. Baxter.
Pp. lv + 397 + 16 plates. (Edinburgh and London: Oliver and Boyd, 1935.) 25*s*. net.

HALF a century ago, Harvie-Brown projected a great co-operative work on the vertebrate fauna of Scotland, each volume to deal with one of the zoo-geographical divisions delimited by the principal watersheds and other natural boundaries. The greater part of the scheme was accomplished, with valuable results, but some gaps remained: one of these has now been filled, through the successful undertaking by Misses Rintoul and Baxter of the task which William Evans did not live to complete. Considering the great disparity in time, the unity of the series is chiefly important on the historical side, and as a contemporary account the new book must stand on its own merits. It can well do so.

This volume on "Forth" is, indeed, of value from much more than a local point of view. It deals with a highly interesting region, which constitutes almost a cross-section of Scotland at the junction of Lowlands and Highlands, and includes a wide variety of country. The region consists of the drainage area of the River Forth, and of all the lesser streams that flow into its great estuary between St. Abbs Head and Fife Ness. On the map it appears roughly Y-shaped, two long arms enclosing the Firth of Forth and a shorter stem following the valley to its head. On the east it has its island outposts such as the Bass Rock, and on the west the land rises above 3,800 feet at the summit of Stobinian. The whole of three counties and large parts of five others are included, with fragments of three more.

There is thus a great diversity of environment, from the waters of the firth with their seals and gannets to the high mountains with their blue-hares and eagles. There is, too, the added interest attached to a transitional zone: it approaches, for example, the northern limit of the garden-warbler and includes the most southern point in the range of the Scottish ptarmigan. Birds, of course, bulk more largely in the book than all the other vertebrates together: the fishes are rightly dealt with quite briefly, as the purely marine forms cannot be very usefully discussed on this regional basis. The major interest is therefore inevitably for the ornithologist.

The two experienced naturalists who have written the book are well equipped for the purpose. They have lived all their lives in the area, giving much time to study of its fauna, and they have already made numerous and notable contributions to the subject. During the last ten years, moreover, they have systematically worked the area with the special object in view, visiting all parts at every season. The statements as to present status and distribution are therefore based to a remarkable extent on first-hand observation —although the help of others has also been freely used—and are definite, comprehensive and up to date. As was to be expected, the authors are particularly informative regarding migratory movements of the birds: in a special chapter they deal generally with this topic, and throughout the avifaunal section are to be found the abundant results of their well-known work on the Isle of May.

As it fortunately happens, there is also available a wealth of information relating to earlier times, and the published sources of this have been diligently and critically examined. It has thus been possible to present some picture of the effects which changes in the environment have wrought upon animal life in the area: a special chapter is devoted to this aspect, and there are also numerous references in the main body of the work which bring out points of much interest.

The modern standard for regional faunistic studies is a high one; but Miss Rintoul and Miss Baxter have produced a volume which can take its place among the very best of its kind. A. L. T.

The Systematic Identification of Organic Compounds:

a Laboratory Manual. By Prof. Ralph L. Shriner and Prof. Reynold C. Fuson. Pp. ix+195. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 11*s*. net.

INTEREST in organic identification work in the University of Illinois was first aroused by Prof. C. G. Derick in 1908, and the course was developed by Prof. O. Kamm, whose book on the subject, published in 1922, is widely known. The present volume is based on a one-semester course of two three-hour laboratory periods a week, now in force at the University of Illinois for students who have had a year of organic chemistry.

By means of a systematic examination of its solubility relationships, the unknown organic compound is relegated to one of nine solubility classes. Classification reagents are then introduced, and the search is narrowed to members of a few homologous series. Physical constants are next noted, and suitable derivatives are prepared. The subject is handled on these lines in a clear and up-to-date manner, and the book contains full practical directions, and many tables of physical constants. A later chapter deals with the separation of mixtures.

The authors have provided a useful manual for a type of work in which "the student's faculty for careful observation, his ability to make correct deductions from his observations, and his originality in planning his work are at a premium". It is clear that this sort of training provides excellent experience for those preparing for research work in organic chemistry.

Industrial Electronics

By F. H. Gulliksen and E. H. Vedder. Pp. xiv+245. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1935.) 17*s*. 6*d*. net.

IF the reader is not full of wrath when he discovers, by diligent search or by stumbling over a single sentence on page 41, that this book denies communication engineering a place in industry ("This type of equipment is used primarily for communication purposes, which is outside the scope of this book"), he will like it; its English is in general well above the level of the unhappy example which has intruded itself here. Even without its applications in the communications industry, "industrial electronics" is a wide subject of very general appeal. The engineer will find the book interesting and valuable, not merely for the large amount of detailed information which it provides on applications already effected, but also because it is stimulatingly suggestive of new applications and developments yet to be made. The authors have succeeded in compressing a great deal of information into a relatively small compass, but the compression has been carried too far; clarity and ease of reading have been sacrificed. Fig. 85, p. 67, will suffice as an example of loss of clarity which might have been avoided by adding three lines of text.

Among the applications outlined are light-sensitive controlling, indicating and recording devices (such as door controllers, smoke indicators, colour matchers), timing devices for welders, rectifiers and inverters, etc. A final and valuable section of the book deals with electronic regulators, including anti-hunting circuits, speed and voltage regulators, etc.

The book is well worth reading; its very defects stimulate thought.

Der Schwammspinner (*Porthetria dispar* L.) in Euroasien, Afrika und Neuengland

Von Dr. Karl E. Schedl. (Monographien zur angewandten Entomologie, herausgegeben von Prof. Dr. K. Escherich, Nr. 12.) Pp. iv+242. (Berlin: Paul Parey, 1936.) 16 gold marks.

THE main idea, underlying the production of the monographic series to which this memoir belongs, is to provide the latest and fullest scientific information with respect to specific subjects of economic importance. The purely scientific and economic aspects of entomology now intergrade so much that Dr. Schedl's contribution, like its predecessors, contains matter of interest to workers in both these fields. Its subject is the insect known in English as the gypsy moth which, although now extinct in Great Britain, is a pest of forest and shade trees more or less all through the South Palæarctic region to Japan. Its entry and spread in North America, and the prolonged campaign for its control on that continent by biological means, have often been recounted. In the present memoir a very complete account will be found of the biology, influence of environment, distribution, natural enemies and methods of control of this familiar insect. There is also a useful summary of Goldschmidt's famous work on sex determination, which has brought the name of gypsy moth to the notice of many biologists. The reader will, therefore, find little to complain of on the score of completeness of information, while the long list of references given will satisfy any crave to delve further into the subject. The work is well up to the standard of other contributions in its series and needs no further commendation.

A. D. I.

Die Blatt-Minen Mittel- und Nord-Europas:

Bestimmungs-Tabellen aller von Insekten-Larven der verschiedenen Ordnungen erzeugten Minen. Von Prof. Dr. Martin Hering. Lief. 2: Brunella—Filipendula. Pp. 113–224+2 plates. (Neubrandenburg: Gustav Heller; 's-Gravenhage: W. Junk, 1936.)

THE attention of entomologists and botanists is directed to "Die Blatt-Minen Mittel- und Nord-Europas" (including England) edited by the well-known authority, Dr. Martin Hering. It is to be completed in 5–6 Lieferungen, each being issued at a subscription price of 12 gold marks, and the publishers state that the work will be completed by the middle of 1937. The whole monograph will comprise about 700 pp. with 500 text-figures and 7 plates. The part to hand (Lieferung 2) is arranged alphabetically under plant genera: it consists of diagnostic tables of all known leaf-miners affecting each genus referred to. The work is evidently designed to facilitate easy reference and will cover the chief aspects of its subject.

Correlation of the Coal Measures

THERE are two quite different aspects of Coal Measure correlation. In the first place, there is the desirability of dividing the thousands of feet of Coal Measure strata into zones or other subdivisions, which can be recognized in different coalfields and can be used in the comparison of sequences in different areas; in the second place, there is the demand of the mining engineer for criteria which will make it possible for him in a given area to identify individual coal seams or other rock beds. The broad zoning has its economic uses in the exploration of undeveloped areas in known coalfields and in the interpretation of deep borings into concealed coalfields. In these preliminary stages, it is sufficient to know what part of the Coal Measures has been reached, but as mining operations proceed, especially in areas where seams are much disturbed and faulted, there is need for much more precise information than can be gained from a study of zones which may themselves be hundreds of feet thick.

For many years, the methods of correlation of the Coal Measures lagged behind those used in other formations. When nearly every other system had been divided into palæontological zones, the Carboniferous rocks were still unzoned, and even then zonal methods were applied to the Lower Carboniferous before much progress was made with the Upper. Meanwhile, however, much success attended the work of geologists who used lithological characters and matched sequences with reference to the distribution of coals, and such workers as Wheelton Hind and Stobbs found valuable datum planes in the marine bands which mark temporary but widespread incursions of the sea into the area where Coal Measures were deposited.

The advances in Coal Measure correlation which have taken place in the past ten years were summarized in a discussion in Section C (Geology) of the British Association during the recent Blackpool meeting; geologists certainly can no longer be charged with neglecting the study of correlation in the rocks which are of most economic importance. It has to be emphasized, however, that the needs of the mining engineer can only be met by a scheme of correlation much more detailed than those developed in almost any other formation, and while zonal classifications of the Coal Measures are now available, efforts are being made to develop methods which will facilitate the identification of individual seams.

The most important fossils for the zoning of the Coal Measures are the plants and those lamellibranchs (*Carbonicola, Anthracomya* and *Naiadites*) which are now believed to have lived in 'non-marine' (if not wholly freshwater) conditions; while the marine bands form useful reference planes, they are too few and their fossils too restricted to afford a general basis for zoning. The non-marine shells have provided six major zones; these are now recognized in practically every coalfield in Britain, and a similar sequence is known on the Continent in coalfields so far afield as the Donetz basin. The precise limits of some of the zones are rather indefinite, but they appear to afford a reasonably secure basis for correlation. Several of the zones can be subdivided: Dr. W. B. Wright has used a number of sub-zones in working out the structure of the Lancashire coalfield, and Dr. J. Weir and Mr. D. Leitch have found that certain of these can be recognized in the Scottish coalfields.

In limited areas, these 'mussel' shells are often sufficiently characteristic of the roof of a seam to be an infallible means of identification. Some mussel bands have long been used in this way: in the highly disturbed anthracite area of South Wales, recognition of the worked seams by means of these faunas is now an established practice. The nomenclature of these excessively variable shells presents a difficult problem, but the closeness of correlation is greater than can be expressed by lists of specific names. Mr. S. G. Clift demonstrated this for horizons in Nottinghamshire and Scotland.

Detailed zoning by means of fossil plants is a still more recent feature of Coal Measure correlation in Great Britain, although on the Continent plant-zones were being used some years ago. The palæobotanical work of Kidston and others, however, laid the foundation of an accurate nomenclature of the plants, and by collecting systematically from an established sequence in South Wales, Dr. Emily Dix has recently been able to subdivide the Coal Measures into zones which appear to be traceable over the whole of Britain. The results of this plant correlation in all the areas yet investigated substantiate the results based on the Lamellibranchs; as plants are usually abundant in those places where shells are rare, these two methods may often be regarded as complementary.

One striking result of the closer correlation of the sequences in various coalfields has been the recognition of the wide distribution of some characteristic bands. The great extent of certain marine bands (the equivalent of the Mansfield

Marine Bed is known in practically every coalfield from Scotland to South Wales and Somerset) proves that occasionally very wide areas were submerged; the remarkable frequency with which thick coals occur at comparable horizons in different coalfields (as at the base of the *Similis-Pulchra* Zone) also suggests a comparative uniformity of conditions at certain stages in Coal Measure times. For some years, there had been a tendency to assume that the basins in which the Coal Measures were deposited were restricted in extent and more or less coincident with the existing coalfields: it was thus thought that the freshwater shells could not be used for correlation since they were only of local occurrence. Their wide distribution and the similarity of their sequences in different countries indicate at least a free communication between the areas.

Work on the spores of the coals has likewise tended to reveal the wide lateral extent of characteristic features. The classic investigation by Dr. L. Slater and others of the distribution of megaspores in the Silkstone and Better Bed coals of Yorkshire and the Arley of Lancashire, which confirmed the correlation of the Better Bed with the Arley, already put forward by Dr. D. A. Wray on stratigraphical grounds, clearly showed the value of these methods, and lent further support to the view that the main coals of these two coalfields were formerly continuous.

More recently, Dr. A. Raistrick has developed with remarkable success a technique for the examination of the microspore content of seams. He has applied this method to the coals of Northumberland and Durham, many of which appear to have a characteristic microspore content which persists over wide areas. He has recently been investigating the difficulties which are introduced by changes in the structure of the seams and in the chemical and physical properties of the coals. The various methods of using spores (both megaspores and microspores) in correlation, and the problems which arise in that work, are also being explored by the Government Department responsible for fuel research (Mr. J. J. Walker and Dr. J. O'N. Millott gave an account of this work).

There can be little doubt that these methods will be of immense importance in the identification of seams, especially in the Lower and Middle Coal Measures, where the floral changes are most pronounced. In the highest Coal Measures, as Mr. G. A. Kellaway showed, the microspore content of successive seams is much less varied, and these methods of correlation present greater difficulties. They are likely, however, to be of great use in the parts of the Coal Measures which are most worked. They will probably supplement rather than replace the use of the plants and shells, from which conclusions can generally be reached so much more rapidly.

A. E. TRUEMAN.

Bracken as a Weed

THE Brake Fern or Bracken (*Pteridium aquilinum*) is an ancient plant of world-wide distribution in temperate and even tropical parts. Although a plant favouring the less dense woodlands and deeper soils, it may invade and dominate grass or heather even on shallow soils where the winters are not too severe or the summers too dry. This characteristic has made it a serious agricultural pest not only in Britain but also in Australia and New Zealand.

During the past forty or fifty years, the spread of bracken, especially in Scotland and Wales, has been so excessive that in many cases the available grazing land has been reduced by one half or more. This is not the only loss, however, for sheep which have been struck by the maggot fly (*Lucilia sericata*) take cover in dense bracken (which they normally avoid) and die there, although many could have been saved if treated in time. These carcasses are the breeding ground for more maggots. From the farmer's point of view, bracken (i) reduces the total grazing available and the number of sheep the ground should carry, (ii) leads to loss of sheep each of a value of 20*s*.–30*s*. or more, and (iii) adds to the costs of management, as in the absence of bracken a shepherd and his dogs can work a greater area of sheep-run.

The spread of bracken is due to many causes: (*a*) mild winters, (*b*) discontinuance of its use for thatching, litter, and as a source of potash for soap and manure, etc., (*c*) spore distribution, (*d*) depopulation of rural areas, and (*e*) reduction of cattle and horse grazing. Horses and cattle do not eat bracken extensively—it possesses a cumulative poison in their case—but heavy animals tramping and grazing amidst the fronds damage it and encourage grass. Pigs are the only animals which eat it; they dig up the subterranean stems or rhizomes.

In a moderately dense patch of bracken there will be 40 tons of rhizome and about 10 tons of fronds to the acre. The huge amount of material built up each year is used for replenishing the depleted rhizomes, the formation of new buds for future rhizomes and fronds, for the production of spores and for the elongation of the perennating rhizome—its chief method of spreading. This may grow as much as a yard each year. In this way a 1/40 acre bracken plant could become an acre in extent in 34 years, or 24 such plants could invade 1,000 sq. yd. in a year.

Unfortunately, bracken possesses few natural insect and fungoid enemies, and none of these materially damages it when it is growing in congenial sites. The one effective measure of control is continuous destruction of the fronds, so that the rhizome is exhausted in forming new fronds. The best time is when the frond is almost completely unfolded (mid-June to early July). A second and even a third removal of the fronds may be necessary for the first two years; thereafter the plant is much weakened and a single cut per year for a further two to five years should exterminate it.

Until recently, fronds have been destroyed by the scythe or by the sickle at a rate of 0·5–3 acres per day, at a cost of 3*s*.–8*s*. per cut per acre, and this on land probably worth only a shilling or two per acre. Now various machines have been produced, and this year the Department of Agriculture for Scotland has granted half the purchase price of machines (spread over three years) for areas satisfactorily cut with the Collins' power bracken cutter or the Glaslyn bracken cutter. The former can cut more than an acre an hour and the latter about an acre an hour, thus reducing the cost to approximately 1*s*. 6*d*.–2*s*. 6*d*. per acre. This season other promising machines have been produced: (*a*) the Denny hand scythe, (*b*) for horses or tractors, the Crossley thistle cutter and the Holt bracken breaker, and (*c*) the Allan and the Gordon motor machines. Reports of a demonstration of these and the two former machines appeared in the *North British Agriturist* and the *Scottish Farmer* of September 3 and 5, 1936, respectively*, and results of their use over extensive areas will be awaited with interest.

The employment of chemical sprays and powders applied by autogiro, tractor, horse-sprayer or hand, has so far proved to be costly and clumsy compared with the cutting methods, and often the resulting growth of herbage is less satisfactory.

Developments in Electroplating

WITH the ever-growing demand for materials possessing new and more varied combinations of properties, it is seldom that any one of the commoner metals has all the properties desired for special applications. Suitable mechanical strength may be offset by susceptibility to corrosion, suitable density by insufficient hardness, amenability to mechanical processing by unsatisfactory appearance. The use of alloys of two or more metals affords one important method of escape from these limitations, especially since a small addition of an alloying element often produces profound alterations of properties. On the other hand, since it is frequently only the surface properties which particularly need modification, an alternative method is to cover the surface with a suitable coating. Thus, the metal may be coated with various enamels, paints, or lacquers; or with a thin layer of a different metal which may be applied by direct immersion in the molten metal—as in the production of tin-plate or galvanized iron—by electrodeposition from a solution of a salt of the metal, or by other means.

The two ways of using a metal to modify the properties of another—as an alloying element and as a coating—have both been extensively exploited, but their fields of application have seldom overlapped. Thus the range of utility of steel has been enormously extended by the use of coatings of tin, zinc and cadmium, but no alloys of these metals with steel have found application. Nickel has been used in both ways in relation to steel, but the applications of the respective products have been notably different. Indeed, chromium seems to be the only metal employed both for alloying with steel and as a coating on steel in order to produce the same type of result, namely, a tarnish-resisting surface.

These were among the matters discussed by Mr. D. J. Macnaughtan in introducing a symposium on electroplating before Section B (Chemistry) of the British Association at the recent meeting in Blackpool. The other papers presented were "The Development of Control in Electrodeposition Processes", by Mr. A. W. Hothersall; "Electrodeposited Coatings as Corrosion Preventives", by Dr. S. Wernick; "Non-tarnishable Finishes", by Mr. E. A. Ollard; "Advances in Industrial Electroplating", by Mr. C. F. J. Francis-Carter; and "The Future of Electrodeposition", by Dr. H. J. T. Ellingham. The whole group of papers afforded a survey of the development of electroplating practice, and directed attention to the striking advances which have been made in recent years. The achievements of modern electroplating were effectively illustrated by means of an exhibition specially arranged in conjunction with the meeting by the Electrodepositors' Technical Society.

In the more restricted sense of the term, electroplating connotes the electrodeposition of a thin, adherent coating of a metal over the surface of a metallic object in order to provide a decorative finish, to protect the underlying metal against corrosion, tarnish or wear, or to achieve a combination of these effects. The use of the term is often extended, however, to include a number of cognate electrolytic processes such as : the electrodeposition of relatively thick and very strongly adherent layers of metal for 'building up' worn or undersized machine parts ; the production of adherent oxide coatings on aluminium and its alloys by anodic treatment (anodizing) ; and the electrodeposition of non-adherent layers of metal which, on detachment from the surface on which they are formed, faithfully reproduce details of surface structure (as in the production of electrotypes and gramophone matrices) or the complete shape of an object (electroforming).

Although electroplating became a commercial process nearly a century ago, developments during the last twenty years have been so important as to change completely the scope and status of the industry. The list of metals electrodeposited in plating practice has been extended by the important addition of chromium and, quite recently, of rhodium ; and now comprises zinc, cadmium, tin, lead, iron, cobalt, nickel, chromium, copper, silver, gold, palladium, platinum and rhodium. The anodizing of aluminium and its alloys has been introduced ; and progress has been made in the electrodeposition of two metals simultaneously, so as to produce alloy coatings such as copper-zinc, copper-tin and zinc-cadmium.

Apart from the introduction of new metals and new processes, there has been also an all-round improvement in the quality and reliability of electrodeposited coatings, and an enormous expansion of the range and scale of their applications. Electroplating is now practised as one of the regular series of operations involved in the manufacture of a large proportion of metal articles of industrial and domestic utility.

For the protection against corrosion of a wide range of iron and steel articles and fittings, electroplating with zinc or cadmium has become an important commercial process. Electrodeposited coatings of tin and, in special circumstances, of lead are also being used for this purpose ; and as a result of the new methods employed in rolling mills, whereby steel sheet is produced in the form of a continuous strip, electrodeposition of tin is now becoming a practicable alternative to 'hot-dipping' in the large-scale manufacture of tin plate. Although the particular difficulties which beset the electrodeposition of adherent metal coatings on aluminium have been partly overcome, it is fortunate that, by anodic treatment of this metal and some of its alloys in suitable electrolytes, it is possible to bring about a considerable thickening of the oxide film which normally covers the surface, and thus effectively protect the underlying metal against corrosion. Since, moreover, the resulting oxide layer is a good insulator, is resistant to wear and readily takes up dyes—thus furnishing various decorative effects—it is not surprising that this anodizing process has rapidly found a wide range of applications.

The enormous expansion in the scale of nickel-plating during the last twenty years—it is estimated that an area of about 250 million square feet is now deposited annually—must be partly attributed to the development of chromium-plating. While very thin coatings of chromium on steel are liable to be too porous to afford much protection against corrosion, and thicker deposits are likely to crack, a highly satisfactory tarnish-resisting surface is produced by first coating the steel with a sound nickel deposit and then covering this with a 'flash' of chromium. In this two-stage process, which has been very widely adopted, it is most important that the nickel 'undercoat' shall be firmly adherent, uniform and non-porous ; and the thorough investigation of the factors which determine these properties has led to outstanding improvement in the quality and reliability of electrodeposited nickel coatings. The now widespread use of chromium as a non-tarnishing finish on base metals may be paralleled by the similar application of rhodium on the precious metals. Thus an extremely thin flash of this hard and highly resistant metal on silverware furnishes a lustrous surface, barely distinguishable in appearance from that of silver itself—but which does not require periodic cleaning.

In all these new developments important parts have been played by the metallurgist, the physicist, and especially the chemist. As a result of careful study of the functions of various ingredients in plating baths, considerable simplification of the older 'formulæ' has been effected, and it has become possible to exercise a much more exact control over conditions of operation, and hence over the character and properties of the deposit. The study of the influence of the pH value of solutions, especially in the deposition of nickel, has been important in securing adherent deposits free from pin-holes. Investigation of the factors which determine the 'throwing-power' of plating baths has led to the development of solutions which yield deposits of almost uniform thickness over the whole surface of an object of complicated shape. Examination of the effects of various kinds of 'addition agents'—especially colloids and other substances of high molecular weight—in the solution, has resulted in the production of smooth, coherent coatings from baths which otherwise yield coarsely crystalline, irregular or spongy deposits ; and is now leading to the direct production of coatings so lustrous as not to need polishing—a matter of some importance when the size or shape of the article or the nature of the deposit renders the polishing process difficult and costly, or where a particularly smooth surface is a necessary condition for the success of a subsequent process, such as the deposition of chromium on electrodeposited nickel.

The introduction of quantitative tests for such properties of the coating as hardness, porosity, internal stress and adhesion, has enabled these properties to be correlated with the conditions of deposition and hence to be brought under control. Microscopical examination of etched surfaces and sections has done much to indicate the size, shape and general arrangement of the crystallites of which the deposit is built up, and even to detect the presence of non-metallic matter, such as oxides, which may enter the deposit, probably in the colloidal state, and profoundly affect its properties. Such problems are now being further investigated by X-ray and electron diffraction methods.

Although the thickness which an electrodeposit should attain in order to fulfil its purpose depends not only on the nature of the metal deposited but also on the character of the basis metal and the conditions of service to which it is to be subjected, the following values (expressed in thousandths of an inch) give a general indication of the thicknesses of various metal coatings used in ordinary practice : lead, 3 ; nickel and silver, 1 ; zinc, 0·5 ; cadmium, 0·3–0·5 ; tin, 0·2–0·5 ; oxide film on anodized aluminium, 0·04 ; chromium (over nickel), 0·02 ; gold, platinum, palladium, rhodium, less than 0·01. These figures may be compared with 0·023 for the wave-length of sodium light and 0·0001 for the thickness of the air-formed 'passive' film on chromium, expressed in the same units.

The introduction of scientific control at every stage of electroplating processes, including the very important preliminary cleaning operations required to free the surface of the basis metal from traces of oxide, grease or other impurities which would prevent perfect adhesion of the coating, has raised the general standard of quality and reliability of plating to a remarkable extent, and given users confidence in its value for a wide range of new industrial purposes. The resulting increase in demand has stimulated the development of mass production methods for plating articles in automatic plants. The articles to be plated are carried at a regulated rate by conveyor chains through a succession of tanks and chambers in which the operations of cleaning, washing, plating, rinsing and drying are conducted in their proper sequence and each for its appropriate time. Although the modern type of automatic plating plant dates back only to 1929, twenty-seven such plants are now working in Great Britain. They operate on the deposition of pure metals such as zinc, cadmium, tin, nickel, chromium, copper and silver ; of alloys such as copper-tin, copper-zinc and zinc-cadmium ; and where no intermediate polishing is needed, successive deposits such as nickel and silver or copper and nickel may be produced in proper sequence ; or finishing processes such as 'oxidizing' or chemical colouring may be carried out at the conclusion of a plating operation. Such plants are often of very large capacity. Thus, whereas a few years ago a 500 gallon plating tank would have been considered very large, 3,000–5,000 gallon tanks are now common, and the largest plant now operated in Great Britain—a nickel plating plant—has a tank capacity of 12,000 gallons, which represents about 60 tons of solution containing about 13½ tons of nickel sulphate.

Improved control of the electrodeposition process has also led to notable developments in fields somewhat outside that of standard electroplating practice, such as the deposition of hard, wear-resistant facings on press tools, printing cylinders, gauges, etc. ; the building up of worn machine parts ; and the production of seamless metal tubing by depositing a thick, non-adherent coating of metal on a mandrel rotating in a plating bath. Cylindrical shells of copper deposited in this way may be slit up to form sheet, with mechanical properties superior to that of ordinary rolled sheet. By successive deposition of two metals, for example, copper and nickel, 'bi-metallic' sheet may also be produced.

With a continuance of the close co-operation which has now been established between the research laboratory and the plating shop, there is every reason to believe that all the lines of development referred to above will be extended. Additional metals will no doubt be introduced into plating practice, in some cases probably by the use of non-aqueous solutions ; and the whole field of alloy deposition is only just beginning to be explored systematically. Methods of control of existing processes will be still further improved, and new developments in various other industries will undoubtedly open up a variety of new and hitherto unsuspected applications of electroplating.

London University Degrees: a Faraday Letter

At the recent celebrations of the centenary of the University of London, the Royal Institution presented to the University a letter written by Faraday on August 10, 1859, to the Rev. John Barlow, F.R.S. The special appropriateness of the gift for the occasion lay in the reference the letter contains to that pioneering activity of the University, the institution of degrees in science. With the movement to accord full recognition to science as an object of academic study Faraday was, it is scarcely necessary to say, in complete sympathy. He was indeed actively concerned in the measures taken, for he was a member of the Senate of the University at the time, a circumstance which adds point to his comments. As this and other points in the letter may be of interest to readers of NATURE, it is printed below.

Hampton Court Green
10 Aug. 1859

My dear Barlow

It was very kind of Mrs. Barlow to write to my wife, and I think that a letter from me to you, is hardly the fit way to acknowledge it :—yet as I write to you you must say something fit for us, with our kindest remembrances, and I expect my wife will write soon. We are exceedingly glad to hear that your journey has been good—your company a happy one—& your present life healthy & joyous. Before I forget remember me to Mr. Esmead—I cannot tell whether I have been at Spa, or have any friends there ; if there are such I dare say you will find them out. We are jogging on or rather we are *not* jogging on :—for on Monday last the workmen ceased to come, the builders strike being on. As far as I can learn, both Masters & Men enter *quietly* into it ; so that though it seems as if it might come to an end in a few days, it may perhaps go on for some time & cause great distress and trouble. We must just wait.

I am not able to give Mrs. Barlow's message to Tyndall, for I think he started last Monday Morning for Chamounie, and I have not seen him since Saturday. Frankland goes with him. He spoke of taking the higher optics for his next course of lectures, and I agreed with him in the propriety (if he saw occasion) of spending £20 on apparatus fitted for the course and for investigation. I do not suppose that he will come across any clear good optical *rock salt*, but we find great difficulty in raising it from the mines in England. Indeed it is rather an impossibility than a difficulty.

As I have been out here with only runs into town I really know very little of what is going on there :—and what I learn I forget. The Senate of the University accepted and approved of the Report of the Committee for Scientific degrees, so that that will go forward (if the Government approve) and will come into work next year. It seems to give much satisfaction to all who have seen it, though the subject is beset with difficulties :—for when the depth & breadth of Science came to be considered, and an estimate was made of how much a man ought to know to obtain a right to a degree in it, the amount in words seemed to be so enormous as to make one hesitate in demanding it from the student :—and though in the D.S. one could divide the matter and claim eminence in one branch of Science, rather than good general knowledge in all—still in the B.S. which is a progressive degree a more extended though a more superficial acquaintance seemed to be required. In fact the matter is so new & there is so little that can serve as previous experience in the founding and arranging these degrees, that one must leave the whole endeavour to shape itself as the practice & experience accumulates.

We have had very hot weather but it is & has been cooler for a few days— The Thames has very rarely been seen so low in water here, as it is now. In London its bad condition seems to increase ; or else my nose accustomed to a better odour here feels it more. The harvest all round us is nearly in ; being very early ; but they tell me the corn is not so heavy as was to be desired. Want of rain has kept it small.

Ever My dear Barlow
Very truly yours
M. Faraday

Dear Mr. Barlow

My right hand Jane being absent in Scotland I am afraid my husband has promised more for me than I can perform so Mrs. Barlow will kindly take Mr. Faraday's letter as an answer with my best remembrances

Sincerely yours
S. Faraday

The letter is, first of all, an admirable example of the simplicity and directness of its author's style as a letter writer. It is written from the house on Hampton Court Green which had, only in the previous year, been placed at Faraday's disposal as a summer residence by Her Majesty the Queen—on the Prince Consort's suggestion it is said. The workmen spoken of were engaged that summer on alterations at the Royal Institution, and their strike evidently went on for many weeks, for it was reported in November that the work had been much delayed by it. The Rev. John Barlow, to whom the letter is addressed, and who was abroad on holiday with his wife, was at the time nearing the end of a long period of office as secretary of the Royal Institution. The correspondence which is preserved shows that out of their association in the business of the Institution there had grown up, between the Faradays and the Barlows, a close and affectionate friendship.

John Tyndall, whose lectures and activities in Switzerland are mentioned, had been Faraday's junior colleague since his appointment to the professorship of natural philosophy in 1853, and had long since been admitted to the intimate circle of the home at Albemarle Street. That Tyndall's search for rocksalt of optical quality was ultimately successful is evident from the valuable collection of prisms, lenses and rough blocks of the mineral, formerly his property and used in his researches, now in the possession of the Royal Institution. A large block was presented to him by the King of Würtemburg in 1867.

The letter contains one of Faraday's not infrequent references to his loss of memory—and a complaint on a different matter, the insanitary condition of the River Thames, a favourite topic, his strictures on which had provoked, a few years earlier, a cartoon in *Punch* of Prof. Faraday, holding his nose, rebuking Father Thames from the side of a steamboat.

The postscript is in Mrs. Faraday's handwriting, and the reference is to their niece Jane Barnard, who lived with them at the Royal Institution.

T. M.

Obituary

Prof. H. L. Le Chatelier, For. Mem. R.S.

The death of Henry Louis Le Chatelier, which occurred at Miribel-les-Échelles on September 17, removes one of the great pioneers in the physical chemistry of the last quarter of the nineteenth century; he was born in Paris on October 8, 1850. His father, Louis Le Chatelier, who died in 1873, was a man of high technical abilities and scientific talents; in 1842, when France possessed only six hundred kilometres of railroads, he was put in charge of railway development and became largely responsible for the construction of the present French railway network. Louis also played a great part in the perfection of the locomotive, in the improvement of coal mining and utilization, in the manufacture of open hearth steel and of aluminium and in the organization of the Bordeaux pine forests.

The intense application of scientific methods to practical ends which marked the career of the father, gave direction to the life-work of the son. Henry Le Chatelier was essentially a scientific man of great talents and resource but most of his work seemed to aim at some technical application; the tendency of his mind was well shown in a money gift which he made to the Académie des Sciences in 1922 with a condition that the income should be given to "persons possessed of such scientific aptitude and facilities for work as would enable them to carry out essentially scientific work involving precise measurements which would be sooner or later applicable to industry". The same interests were manifested in the frequent occasions on which he exhorted his countrymen to apply scientific methods to the improvement of industrial practice; the work of F. W. Taylor in the United States on scientific management first obtained publicity in France through Le Chatelier's writings.

Le Chatelier was educated at the Collège Rollin, the École Polytechnique and the École des Mines; he taught at the latter school and at the Collège de France and in 1907 succeeded Moissan as professor at the Sorbonne. As the fundamental importance of his work became universally recognized, honours came in rapid succession. He was a Grand Officer of the Légion d'Honneur and was elected to the Chemistry Section of the Académie des Sciences in 1907; he became a foreign member of the Royal Society in 1913 and received the Davy Medal in 1916. He was made a foreign member of the Chemical Society in 1908 and an honorary member of the Institute of Metals in 1913; an associate member of the Académie Royale de Belgique in 1913, a foreign member of the Accademia dei Lincei in 1918, and an *Ehrenmitglied* of the German Chemical Society in 1931. He was a Président d'Honneur of the French Chemical Society and probably its senior member, having been elected in 1878.

Le Chatelier early devoted himself to the study of the thermal changes which accompany chemical reactions and dissociations, following in this Berthelot and his teacher Sainte-Claire Deville; his work on this subject is monumental and he contributed much to the application of thermodynamics to chemical reactions. His experimental work was characterized by a delicacy previously unknown and was accompanied by mathematical analysis of a searching character; thus, he was able to predict that calcium carbonate should be appreciably dissociated by water vapour at the ordinary temperature and to show experimentally that the prediction is correct. His great generalization now known as the principle of mobile equilibrium dates from 1884 and states that "toute transformation infiniment petite d'un système en équilibre chimique qui est produite par la variation d'un seul des facteurs de l'équilibre s'éffectue dans un sens tel qu'elle tende a produire une variation en sens inverse du facteur considéré". He introduced great improvements in the methods of determining heats of reactions, specific heats of gases at high temperatures, explosion pressures and in the optical measurement of high temperatures. He made the thermoelement an efficient instrument for the determination of high temperatures in face of the criticisms of Regnault, who thought that the use of such an appliance involved sources of error which could not be eliminated; he was the first to use the platinum–platinum-rhodium thermoelement in thermochemical practice. Le Chatelier established a number of principles connected with the second law of thermodynamics which now form part of our classical knowledge of gas reactions; in this connexion he took out a patent for the synthesis of ammonia which anticipated the Haber process, now so widely used.

Le Chatelier extended the work of Vicat, a friend of his grandfather, on hydraulic cements and was the first to apply petrological methods to the study of this subject; he thus identified several components of Portland cement, and his researches in this connexion still form the framework of our knowledge of cements and mortars. He was a pioneer in the application of heat dilatation, electrical conductivity and etching methods to the study of metals and their alloys.

In this brief notice it is impossible to give any adequate account of the vast field covered by Le Chatelier in the course of his original work; some mention should be made, however, of his literary activities. In 1899 he published a French translation of the papers of Willard Gibbs, with the work of whom his own was so closely interwoven, and he founded the *Revue de Métallurgie* in 1904. He published a series of lectures on carbon in 1908 and, with the collaboration of his daughter, Madame Jean Royer, produced in 1925 a book of more general appeal entitled "Science et Industrie". These two books reveal Le Chatelier as he was known to his friends—a profound and original thinker and a high-minded and patriotic Frenchman with a deep sense of humour. His reminiscences of his old friends were many and usually combined wisdom and jest. Thus he recalled that Sainte-Claire Deville was a discursive lecturer who furnished his students with little likely to be of service in the approaching examinations. He likened the chemical affinity between sulphuric acid and potash to that existing between a dog and a bone; the dog has an affinity for the bone but it may be equally claimed that the bone has an affinity for the dog and the two mutually absorb each other to form one single entity. The only difference lies in the fact that the dog has personal feelings which are absent in the bone; but how can one say which is the more noble, the acid or the alkali? In such a manner Sainte-Claire Deville expressed his antipathy for so-called scientific theories in which empty words often stand for non-existent ideas, the term reciprocal affinity serving merely as a vague mode of recalling an experimental fact.

Le Chatelier was a man of fine presence and of courtly manner; he was a brilliant talker and, although advancing years brought deafness, his personal charm always remained. With his death we lose one of the great figures of the scientific France of last century.

WM. J. POPE.

Mr. Sherard O. Cowper-Coles

THE name of Sherard Cowper-Coles is closely linked to the progress which has been made in numerous branches of electrodeposition work during the last half-century. Born in 1867, his first patent was brought out while he was still a minor, although this had no connexion with electrodeposition; thereafter, there has scarcely been a year when his name has not appeared in the index to the *Patent Journal*.

Cowper-Coles's life was largely devoted to work in electrodeposition problems, his speciality being processes of electro-forming and applications of electrolysis which were rather outside the sphere of electroplating. If processes which are connected with the decoration and protection of metal surfaces interested him less, it is nevertheless a curious fact that what may possibly be considered his most important contribution from the industrial point of view was a method of protecting steel which is very widely practised to-day, and to which he gave his name—sherardizing. This process consists in the production of a zinc coating on ferrous articles, not by electrolysis but by cementation; later, it was progressively improved and now finds considerable application.

Among the many problems which interested Cowper-Coles were the electrodeposition of rubber, deposition on glass, sound recording, needle sharpening, production of white lead by electrolysis, transparent paper, sound-proof ventilation, while he also carried out some work on the smoke abatement problem.

For many years, Cowper-Coles worked in a private laboratory, which he built at Sunbury-on-Thames. Here, favoured visitors would be shown over a most fascinating and unique collection comprising examples of almost every aspect of applied electrodeposition, from electrolytic copper gramophone records to electrodeposited iron tubes of giant size. Most of these exhibits had been produced by Cowper-Coles during his lifetime, and some of them were shown at the Electrodeposition Exhibition held last year by the Electrodepositors' Technical Society at the Science Museum.

During the latter part of his life, Cowper-Coles devoted his efforts to the production of sheets by direct electrodeposition processes. He had a considerable financial as well as scientific genius, and a number of companies were formed to exploit his processes. He published a large number of papers in the proceedings of numerous societies and institutions. A man of considerable personal charm of manner, his courtliness was reminiscent of an age long passed. The niche which he filled in the world of electrodeposition was truly unique.

S. WERNICK.

We regret to announce the following deaths:

Sir George Hampson, Bt., formerly assistant keeper in the Natural History Museum, known for his work in entomology, on October 15, aged seventy-six years.

Prof. Alexander Larmor, formerly McCrea professor of natural philosophy in the Magee University College, Londonderry, on October 12.

Prof. Pietro R. Pirotta, formerly professor of botany in the University of Rome, on August 4, aged eighty-three years.

News and Views

Lord Nuffield and the University of Oxford

On October 16, it was announced that Lord Nuffield had offered to the University of Oxford the magnificent sum of £1,250,000 for the development of a post-graduate medical school with a staff of full-time professors. This is the greatest benefaction ever made by an Englishman in his lifetime to a specific public object, and the biggest sum a university in Britain has received since Mr. Carnegie's gift of two million pounds to the Scottish universities thirty-five years ago. Until recently, Oxford's small but good medical school did not engage itself much either in teaching or research beyond the subjects of the second professional examination. The men who had reached this stage were encouraged to continue their work at one of the big training hospitals in London or other large city, and to return to Oxford only to take examinations. In 1927, however, the new school of pathology was built and endowed by gifts from Sir William Dunn and Mr. Theodore Williams, and, more recently, Lord Nuffield made available for medical research the Nuffield Institute by buying the Radcliffe Observatory buildings and surrounding land and endowing it with £16,000. It is now proposed greatly to extend these beginnings so that the comparatively small city of Oxford may have the kind of medical school which in Great Britain has been considered feasible only in a large university city. The main purpose of this, however, will be research, not teaching. Disease is to be studied over the widest possible front; the clinical training of medical students will be incidental and definitely subsidiary.

In his letter to the Vice-Chancellor of the University announcing the gift, Lord Nuffield briefly outlined what he had in mind. He would like clinical departments in medicine, in surgery and in obstetrics, and a department of anæsthetics, to be established immediately. Each of these would be under the direction of a new university full-time professor. They and their principal assistants would be so remunerated that their energies could be wholly given to their work in the hospitals and at the University and not, in part, distracted by private practice. The new posts would be open to any qualified practitioner whether a graduate of Oxford or not. Young research students proposing to work under the supervision of seniors on clinical problems would be encouraged. The body entrusted with the execution of the scheme will include representatives of the University, of Lord Nuffield and of the two large hospitals—the Radcliffe Infirmary and the Wingfield-Morris Orthopædic Hospital—which will be mostly concerned. These and the Oxford Eye Hospital contain approximately seven hundred beds and serve a district extending in some directions nearly thirty miles from the city, which contains a quarter of a million people. Much of the credit for advising on the objects to which the benefaction will be directed is due to the regius professor of medicine, Sir Farquhar Buzzard, and it is a matter of satisfaction in Oxford that the new scheme will be begun under his guidance. Not content with this great benefaction for medical studies, Lord Nuffield has also given £100,000 to the University to help its endowments generally. The University is at present deeply committed financially for the building of the great Bodleian extension, and until that building is paid for, money for the extension of the scientific departments cannot be so readily available as otherwise. This gift, accordingly, makes more hopeful, although indirectly, the provision of two new science laboratories which are badly needed—a new University department of physical chemistry, and the replacement of the Clarendon Laboratory for physics.

Belluno Earthquake of October 18

At about 4 a.m. (3 a.m., G.M.T.) on October 18, a destructive earthquake occurred in northern Venetia and caused considerable loss of life and damage to property. The centre seems to have been close to Sacile, which lies about thirty-seven miles north of Venice and twenty miles south-east of Belluno. The area of damage is not less than forty miles in length and includes Belluno, where nearly all the old buildings were injured, Borgato Zago and Conegliano. The shock is said to have lasted twenty seconds and was felt at Milan, 166 miles to the west of Sacile, so that the disturbed area may contain about ninety thousand square miles. On June 29, 1873, there was a similarly destructive earthquake in the Belluno district, which was carefully studied by Höfer, Bittner and others. According to these investigators, the epicentre lay about two miles to the east or south-east of Belluno. Höfer assigned the origin of the earthquake to movements along two faults, one directed nearly north-east and south-east, and the other east, from the epicentre. He estimated the depth of the focus at 7·91 km., or very nearly five miles. It would thus seem that, in the recent earthquake, the centre was displaced some miles to the south-east to a point on, or not far from, the north-easterly fault marked out by Hofer.

Science in South Africa

In his presidential address to the South African Association for the Advancement of Science on October 5, at Johannesburg, H.E. the Right Hon. the Earl of Clarendon, Governor-General of the Union of South Africa, after referring to the part which applied science has played in the transformation of Johannesburg during the last fifty years, discussed particularly the part which the work of the man of science plays in everyday domestic, social and business life. The work which the Association is doing to bring home to the ordinary man the great debt which he owes to the scientific worker entitles it to the support not only of scientific men but also of the general public, and Lord Clarendon suggested that this is one of the most important aspects of the Association's work. Referring to the efforts of the scientific worker in the matter of health, nutrition and disease, he pointed out that much as we already owe to the discoveries of science, much more could be done if the requisite funds were available. Essentially the eradication of malaria, nagana, East Coast fever, tuberculosis in cattle is a matter of funds, lack of which prevents the carrying out of measures already known to be effective.

ACCORDINGLY Lord Clarendon argued that the support and fostering of scientific research should not be limited by national frontiers. The best utilization of national wealth involves the utilization of discoveries made elsewhere. Many scientific problems have been solved by international co-operation, and while the influence and guidance of politicians and financiers may still be necessary, we can also look forward to a brighter future in which a large proportion of the troubles of the world will be treated as scientific problems and dealt with on this basis by international congresses of men of science. In furthering this ideal, the diffusion of a knowledge of science and of the world's debt to scientific investigation is of vital importance. In a reference to the place in science of the amateur, Lord Clarendon suggested, contrary to the usual belief in scientific circles, that specialization has so handicapped the work of the amateur, at any rate in the physical sciences, that his contribution is now becoming insignificant, that the growth of leisure would greatly increase the number of amateur workers, particularly in the conception of leisure as "the opportunity to work hard at things which really interest one".

Research and Finance

A MEMORANDUM on the development and finance of the Department of Scientific and Industrial Research was discussed in a leading article of NATURE of July 11 last. The view appears to prevail that this memorandum embodies the considered views of the Parliamentary Science Committee; but this is not so. The history of the memorandum is as follows. Some three years ago the British Science Guild and the Association of Scientific Workers appointed a joint committee to explore this question. Considerable material was gathered, and certain progress was made. Eventually the two bodies referred the subject to the Parliamentary Science Committee in 1935, together with the results of their labours. Obviously it was desirable that this material should be collated, brought up to date, and even amplified. This was done by a distinguished scientific worker at Cambridge. His preliminary draft was circulated to the executive of the Parliamentary Science Committee last March. Before proceeding to consider the memorandum in detail, the executive deemed it expedient to refer it to the councils of its constituent bodies and to the individual members of its own general and executive committees to secure their considered views in writing. This has proved to be a leisurely process, as some councils meet at infrequent intervals —and not at all during high summer! A considerable volume of constructive and polemical criticism has been received; and an amended memorandum is now being prepared at Cambridge incorporating many of the suggestions received. It appears, therefore, that the Parliamentary Science Committee has not yet settled down to work, as a deliberative body, on this memorandum. In a sense, the committee may be said to have given it a 'first reading', and committed it to a select committee for consideration before proceeding to the 'second reading' and subsequent stages. The 'Parliamentary draftsman' has to finish his labours before the Parliamentary Science Committee can claim any credit for accepting the result of his public-spirited labours—or for rejecting the memorandum on 'third reading'.

Plant Organisms in Permanently Frozen Subsoil

SOME rather sensational newspaper reports on the discovery, by Russian scientific workers, that organisms which had remained frozen for thousands of years in Siberian soils can be revived (see NATURE, Sept. 26, p. 540), is now followed by an account on this work, carried out by P. Kapterev in the Amurland, at lat. 53° 58′ N. (*Comptes rendus, Academy of Sciences, Moscow*, 3, No. 3; 1936). The depth of the permanently frozen layer at that place has not been definitely determined, but is estimated at about 60 metres. The upper 2·5 metres of the soil may thaw during summer, and below that level the permanently frozen layer begins. This frozen subsoil is loamy and includes some peaty intermediate layers, which probably were formed at the bottoms of pools. Samples of peaty material taken at depths up to 4·25 metres, when placed in flasks with distilled water, invariably developed a fairly rich flora of algæ belonging to some twenty genera such as *Stigocleonium, Mougeotia, Oedogonium, Closterium, Cosmarium, Oscillatoria, Phormidium, Navicula, Gomphonema, Anabaena, Lyngbia, Chroococcus, Ulothrix, Chlamydomonas*, etc., as well as fungal hyphæ and green stems of a Hypnaceous moss. In one sample, a crustacean, *Chydorus Sphæricus* (Cladocera) has been found. The possibility that these organisms were introduced into subsoil by water percolating from upper layers is rejected, since the permanently frozen subsoil is practically impermeable to water. Nor can it be suggested that the cultures were infected accidentally, since it would be difficult to expect then a whole complex of organisms, which moreover varied with the depth of samples. It is considered, therefore, that the organisms actually came from the permanently frozen subsoil. The age of the layers from which the samples were taken is estimated as possibly from one to three thousand years. Carefully planned investigations of still deeper layers are being continued under the auspices of the Moscow Academy of Sciences.

Administrative Classification of Australian Aborigines

A NEW policy for the control of the aborigines under the jurisdiction of the Federal Government of the Commonwealth of Australia is announced by Mr. Paterson, Minister for the Interior (*The Times*, Oct. 4). These aborigines, that is, the inhabitants of the Northern Territories only, are estimated to number approximately 20,000 out of a total aboriginal population of 76,000, of whom 22,000 are half-castes. In future they will be classified in three divisions: (1) detribalized natives, such as those near Darwin and other northern towns; (2) tribes on or near pastoral stations and other white settlements; and (3) aborigines beyond civilized control. This classification corresponds broadly with the facts, and will involve no very drastic interference with existing conditions. At the same time, official recognition and acceptance of a very real distinction should facilitate discrimination and increase efficiency in administering and applying any ameliorative policy. The disposition of the aborigines proposed under the new regulations is that the completely detribalized aborigines should be educated to a white standard, with the view of training them to become economically and occupationally efficient. Areas are to be set aside at Darwin, on which they will be encouraged to abandon their nomadic habits and to settle in family houses, cultivating the soil and rearing domestic animals. Barracks, schools and recreational and sanitary facilities will be provided. Semi-detribalized natives will be settled in reserves, in which they will be enabled to live in native fashion; and *myalis*, aborigines completely under tribal institutions, will live in the inviolable reserves. The Australian aboriginal has shown himself singularly adaptable to the advantages of white civilization; but it will be interesting to watch how far this experiment in checking so deeply engrained a tribal habit as nomadism meets with success.

Public Lighting

IN his address at the opening meeting of the Illuminating Engineering Society on October 13, the president, Mr. Arthur Cunnington, referred to several questions of outstanding interest in connexion with lighting, such as the need for greater uniformity in conditions of supply of gas and electricity, the desirability of designing fittings that are easy to maintain as well as efficient, and the effect of surroundings on conditions of illumination. In this connexion, he suggested that if owners of buildings would make a practice of steam-cleaning the surfaces of buildings before the period of the Coronation, this would not only improve the appearance of the streets but would also greatly facilitate floodlighting. The concluding section of the address emphasized the value to large consumers of trained lighting engineers who could form an impartial opinion of the merit of different systems and appliances. The need for expert public lighting engineers in large towns and cities has recently been emphasized, but there are many other bodies such as Government departments, railways and docks and large industrial concerns which could benefit from their services.

Progress in Illumination

IN accordance with the usual practice of the Illuminating Engineering Society at its opening meeting, a report on progress prepared by the Technical Committee and summarizing advances in lighting and photometry during the past year was presented, and a series of exhibits was arranged. Among the most striking of these was a new form of small electric discharge lamp (80 watt and 125 watt), produced by leading manufacturers in Great Britain. This lamp, which resembles in size and shape an ordinary filament lamp, is the first of the kind capable of being applied (with only a choke in circuit) on circuits of 200–250 volts (A.C.) for domestic and office use. These lamps have an initial efficiency of 40 lumens per watt and an average efficiency of 30 lumens per watt during life. Of considerable interest also were the demonstrations of the effect of bulbs coated with fluorescent powder, whereby the natural spectrum of the light can be considerably improved, and of various stroboscopic effects. Other exhibits included a model illuminated aerodrome and a model stage, improved forms of catalytic methods of ignition for gas burners, and a method of studying the brightness of illuminated roadways by the aid of accurate photographs taken by artificial light.

The Microscope in Engineering and Industry

THIS was the subject chosen by Mr. A. E. Bingham for the address with which, as chairman, he opened the session of the Junior Institution of Engineers on October 9. After explaining the lens system of the modern instrument, he gave a résumé of its history and evolution to its present capacity for the production of photomicrographs of metallic surfaces with great clearness at high magnifications. In the majority of engineering investigations, the specimens under examination are opaque, and the difficulties of illumination and the most advantageous methods to use were discussed, as also were the preparation of metallic specimens and the making of photomicrographs. The petrological microscope, as used for the magnification of rock sections of less than one thousandth of an inch in thickness, and for their examination under polarized light, was also introduced. Many examples of the applications of microscopy were given, among them the examination and measurement of particles of abrasive powders, determination of the lengths of fibres used in the paper, artificial silk and other industries, checking the results of heat treatment of steel, hardness testing, and the examination of profiles of screws, wheel teeth, and small products by means of the profile projector.

Alcoholism and Psychiatry

THE seventeenth Norman Kerr Memorial Lecture before the Society for the Study of Inebriety was delivered by Dr. D. K. Henderson, professor of psychiatry at the University of Edinburgh and physician superintendent of the Royal Edinburgh Hospital for Mental Diseases, on October 13, the subject being alcoholism and psychiatry. At the outset, Dr. Henderson stated that though the admission rate to his hospital for cases of mental disorder due to alcoholism has been reduced from one half to one third of what it was twenty to thirty years ago, much more could be accomplished by more intense propaganda, educational campaigns and all manner of social influences. It is, however, by the methods and technique of psychiatry that the causation of alcoholism can best be elucidated and the best modes of treatment devised. It is essential, he declared, that alcoholism should be regarded as an illness or disease and not as a crime or misdemeanour, as is still done even to-day by some medical practitioners. Dr. Henderson then discussed alcoholism as a cause of homicide, assault, sex offences with adults or children and suicide, as well as the effect of parental alcoholism on the children and the relation of alcoholism to mental disease. In conclusion, he urged that the lunacy laws, which he said are archaic both in name and form, should be replaced by mental health laws applicable to all groups of nervous and mental disease.

Co-operation in Bibliography

THE movement for co-operation in bibliography has received an important impetus from the Bataafsche Petroleum Maatschappij. This company classifies, by means of the Decimal Classification, 150,000 references annually to literature in chemistry, physics, etc., and their applications. We learn from Dr. S. C. Bradford that, since March last, the firm has contributed copies of its non-secret references to the Science Library, for intercalation, with titles from other sources using the standard classification, in its Subject-Matter Index of 2¼ million references to scientific papers. This valuable contribution exemplifies the new spirit of co-operation in bibliography, which is surely achieving the production of a complete index to the records of discovery and invention. It is interesting to note, also, that Dr. Maximilian Pflücke, the editor of the *Chemisches Zentralblatt*, is collaborating in the production of the German edition of the Decimal Classification.

The Liverpool Biological Society

THE fiftieth anniversary of the Liverpool Biological Society is an event of more than local importance in that the large amount of original work by its members has wide significance, particularly through the foundations laid by one of its most prominent leaders, the late Sir William Herdman. Founded in 1886, the Liverpool Biological Society has since worked in close association with the Department of Zoology of the University of Liverpool, the Lancashire Sea Fisheries Laboratory and the Liverpool Marine Biological Committee which was started as a section of it, but some years ago, on the origin of the Department and chair of oceanography at the University, was absorbed in that. The *Transactions* of the Society have been issued annually and contain a wealth of original papers. The Society has always had distinguished presidents, some prominent past names being Profs. W. Mitchell Banks, Sir William Herdman, R. J. Harvey Gibson, Robert Newstead, P. G. H. Boswell, W. Dakin and J. Johnstone; the present holder of the office is Dr. R. J. Daniel. It was Sir William Herdman, in pre-War days, who succeeded in interesting city businessmen in the Society's activities, thereby increasing its financial support and enabling it to build up a valuable library. In 1924, the Liverpool Heredity Society amalgamated with it, following which special attention was given to this side of biological study. Although the Society's membership was 130 ten years ago, it now musters only about sixty, chiefly connected with the University. With its annual meeting in October, it meets, usually, at the University, every month during winter, with occasional summer excursions.

American Cultural Origins

THE latest addition to the excellent series of "Leaflets" describing the collections of the Field Museum of Natural History, Chicago ("Archaeology of South America". By Eric J. Thompson. Leaflet 33. Field Museum of Natural History, Chicago. Pp. 160, 12 pls., 18 text-figures and 1 map), is an introduction to, and description of, the cases in the museum covering the archæology of South America. An account of the culture of the separate and distinct geographical and cultural areas of the sub-continent is preceded, by way of introduction, by a concise review of current theory of American origins. The indigenous civilization of South America, when the pre-Inca and Inca peoples are taken into account, ranges from the greatest achievements in social organization and material development of the New World before Columbus to what is perhaps the most backward of any culture known among surviving primitive peoples—the culture of the Yahgans of Tierra del Fuego, a people who in their native state have not advanced so far as polishing stone.

THE Yahgans are taken, with reservations, as representing the culture of the earliest immigrants into the continent. The physical characters of the earlier arrivals probably were those of the Lagoa Santa skull type. Such innovations as basketry, bow and arrow and the domestic dog may, it is thought, have been brought in by the third wave of immigration, broad-headed peoples, also coming from Asia. The turning point in cultural development is the introduction of agriculture. Mr. Thompson is inclined to the view, now current, that the origins of the advanced American civilization must be sought in South rather than Central America; and he is disposed to hold that the domestication of plants, which took place about five to eight thousand years ago, began in eastern South America with the cultivation of manioc, rather than, as is generally assumed, in Central America with the development of maize from the wild grass Teocentli (*Euchlaena mexicana*). While Mr. Thompson rejects so low an estimate as two thousand years as the period of man's existence on the continent, he does not consider that a higher antiquity than twenty thousand years is probable.

Artificial Lakes in Africa

A REMARKABLE proposal for the formation of several great lakes in the interior of Africa in order to create cultivable land and stores of hydro-electric power is outlined in a report issued by Science Service, of Washington, D.C. The project emanates from H. Soergel, of Munich. A great dam two and a half miles long about 500 miles from the mouth of the Congo would turn the basin into an inland sea with an area of about 350,000 sq. miles. An outlet by the lower Congo would provide abundant water power or, alternatively, an outlet could be arranged to the north to create a second inland sea centring around Lake Chad, which would drain through existing wadis to the west, north-east and east by a "second Nile" to the Gulf of Gabes in the Mediterranean. This new river would provide irrigation water for vast areas in the French and Italian Sahara. A further suggestion is for a dam on the Zambezi River above Victoria Falls in order to create an inland sea over much of the Kalahari desert. Herr Soergel does not discuss the effect of evaporation on the projected Chad and Victoria Seas, both of which would lie in almost rainless regions.

Bee Control in Czechoslovakia

WE learn from the *Bee World* that Czechoslovakia is taking drastic steps in dealing with Acarine disease. The new law insists on treatment with the recognized British or Frow remedy of all colonies within 10 km. of an infested hive. Stocks found to be weak in mid-August are to be destroyed. The use of methyl salicylate is ordered during the spring up to honey flow, in all stocks discovered to be infested after over-wintering.

Indian Association for the Cultivation of Science

INDIAN physics, under the leadership of Sir C. V. Raman and Prof. M. N. Saha, has an established position; and it is interesting to read, in its report for 1935, a history of the Indian Association for the Cultivation of Science, an institution which has played a large, if not the dominant, part in bringing about this result. The Association was founded in 1870, and the laboratory, built in 1890, later became an active centre of research under the stimulating guidance of Raman, who was succeeded as Mahendralal Sircar professor by Dr. K. S. Krishnan. The financial and administrative arrangements have lately been re-organized and a material annual grant obtained from the Government of India, which accordingly has a voice in the management. The work of the past year covers a fairly wide range and includes studies of molecular structure, of magnetic effects and of optical phenomena. There is, therefore, every ground for anticipating the maintenance of full activity.

Anti-Rabic Treatment at Kasauli

IN the annual report of the Pasteur Institute of India, Kasauli, for 1934, the Director states that 1,471 Europeans and 15,380 Asiatics were treated at Kasauli and associated centres, a total increase of 913 compared with 1933. Of the treated cases, one death was reported among Europeans, and 90 among Asiatics, a mortality among the latter of 0·53 per cent, the lowest death-rate recorded during the last ten years. In addition, 671 courses of vaccine for the prophylactic treatment of animals were issued during the year. The vaccine employed is a carbolized 5 per cent Paris sheep vaccine.

Tuberculosis and Cattle

A FURTHER issue of the Register of Herds attested under the Tuberculosis (Attested Herds) Schemes, England and Wales and Scotland, has been published jointly by the Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1, and the Department of Agriculture for Scotland, Queen Street, Edinburgh, 2. It contains particulars of 117 herds in England and Wales and 144 herds in Scotland which had been attested up to July 31, 1936. Since the previous issue of the Register on March 31, 1936, 36 herds have been added in England and Wales and 56 in Scotland.

Parliamentary Science Committee

LAST April the Parliamentary Science Committee received the adhesion of the Association of British Zoologists. Recently it has had the gratification of the accession of another body devoted to biology, the Association of Applied Biologists. The Committee is already strong in support from bodies devoted to applied and mechanical science, and the strengthening of the biological support was much desired. The aggregate membership of the Committee's constituent bodies is now upwards of 100,000.

International Association for Testing Materials

THE Congress of the International Association for Testing Materials is to be held in London in April next. The subjects to be discussed are divided into four groups, A (Metals), B (Inorganic Materials), C (Organic Materials), and D (Subjects of General Importance), each of which is presided over by a distinguished worker from overseas. The last Congress for Testing Materials was held in 1931, and every effort is being made to ensure that the knowledge in this most important field will be brought completely up to date. The papers will be presented in the form of summaries, so that a vast amount of information will be made available in easily accessible form. Particulars of the Congress can be obtained from the honorary secretary, Mr. K. Headlam-Morley, at the offices of the British Committee, International Association for Testing Materials, 28 Victoria Street, London, S.W.1.

Announcements

THE Right Hon. Lord Balfour of Burleigh, and Prof. John Mellanby, Waynflete professor of physiology in the University of Oxford, have been appointed members of the Medical Research Council, in succession to the Most Hon. the Marquess of

Linlithgow, and Prof. E. D. Adrian, who retired in rotation on September 30. The appointment of Prof. Mellanby was made after consultation with the Medical Research Council and with the president of the Royal Society. Lord Balfour has been appointed to succeed Lord Linlithgow as chairman of the Medical Research Council.

A DINNER will be held at the Hyde Park Hotel, Knightsbridge, London, S.W.1, on November 24, at 7.30 for 8.0 p.m., when the president of the British Science Guild, the Right Hon. Lord Melchett, will preside. At the dinner, a presentation from supporters of the Guild will be made to Sir Richard Gregory, chairman of the Council of Management, in recognition of his services to science generally and to the British Science Guild in particular.

AT a meeting of the Advisory Council of the Imperial Institute on Mineral Resources, Sir Robert Hadfield, who is a member of the Council and has been interested in the mineral work of the Institute for many years past, announced that he wished to make a contribution of £1,000 to promote the compilation of mineral brochures by the Institute. The Director accepted this generous offer with gratitude on behalf of the Board of Governors. In making this offer, Sir Robert emphasized the importance of iron and ferro-alloy metals to the Empire, and expressed a hope that this importance would be recognized in the brochure programme of the Institute.

DR. OTTO KNOPF, professor of astronomy at Jena since 1923 and director of the Jena Observatory since 1900, celebrated his eightieth birthday on September 24, and Prof. Wladimir Köppen of Graz, formerly head of the naval observatory at Hamburg, was ninety years of age on September 25.

PROF. R. ZAUNICK, of Dresden, has been awarded the Sudhoff Medal by the German Society of the History of Medicine, Natural Science and Technique for his lecture on Karl Gustav Carus and his Dresden circle.

DR. WILLIAM HALLOCK PARK has retired from the chair of bacteriology and preventive medicine at the University of New York after thirty-eight years service on the staff of the College of Medicine. Dr. Park is the founder of the New York City Public Health Laboratories, on which he has served for forty-two years as director.

A SPECIAL institute for experimental physiology and therapeutics has been organized at the Pirogoff military hospital, Moscow, where researches will be made in physiology, physiochemistry and biochemistry.

DURING the first five months of this year the number of deaths from motor accidents in New York City fell to 9·3 per 100,000, which is the lowest figure hitherto reached in the towns in the United States. In New York State the number has fallen by 14 per cent, 829 persons having been killed in comparison with 965 during the same period in 1935.

THE thirty-fifth Congress of the Italian Society for the Progress of Science will be held at Tripoli on November 1–7 at the same time as the meeting of the Royal Italian Geographical Society, and will constitute the first Italian Scientific Congress of the Fascist Colonial Empire. The programme will include papers on hygiene and colonial pathology, with special reference to the sanitary, prophylactic and eugenic organization of the Italian colonies. Further information can be obtained from the Segretaria generale, Società Italiana per il progresso delle scienze, Via del Collegio 26, Rome.

THE *Proceedings and Transactions of the South London Entomological and Natural History Society* for 1935–36 form a record of a successful year's activities which close with the Society in a satisfactory financial condition. This publication, which appears annually, contains papers of both general and more specialized interest to naturalists, together with records of field meetings and of various congresses. The most extensive article is by Mr. Kenneth J. Hayward, and is an account of a collecting expedition along the Alto Parana, Argentina, illustrated by interesting photographs.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A chief technical instructor in the Government Trade School, Haifa—The Secretary (SIR/CA), Board of Education, Whitehall, S.W.1 (October 26).

Three technical officers, two assistants (Grade I), and one assistant (Grade II) in the Directorate of Technical Development, Air Ministry—The Secretary, Air Ministry (S.2.D./405), Adastral House, Kingsway, W.C.2 (October 30).

Assistants (Grades I and II) in the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (October 30).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 724.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Dentition of *Australopithecus* *

THE importance of *Australopithecus* as a possible near relative of man is such that it seems but right that the world should have the facts at the earliest moment after they are fully confirmed.

The Taungs ape is represented only by the skull of a six-year-old 'child'; and though some of its human-like characters are due in part to the infantile condition, there are a number of others that seem to show that it is more nearly related to man than to the chimpanzee. Of these, the most convincing is the structure of the milk molars, which agree closely with those of man and differ very greatly from those of the chimpanzee and gorilla. But owing to the superficial general resemblance of the skull to that of a young chimpanzee, many seem still to be inclined to regard the Taungs ape as a variety of chimpanzee.

The discovery at Sterkfontein of the adult skull of an allied species is thus of great importance. It will be some months naturally before a full account of the skull can be published as the bone is very friable, and development has to be done slowly, but as the upper dentition is now almost fully known, a preliminary account of it cannot fail to be of interest.

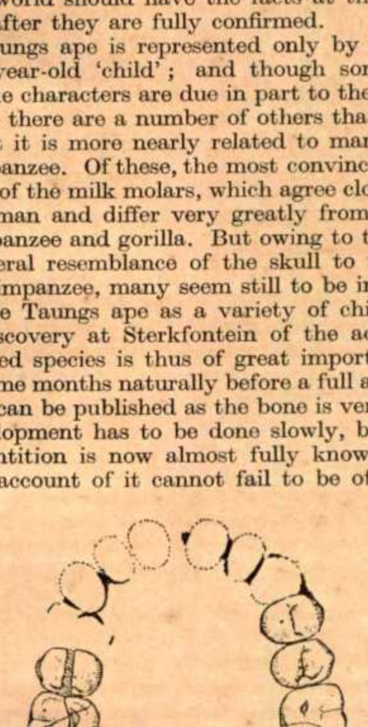

FIG. 1. The upper dental arch of *Australopithecus transvaalensis* Broom. As the maxillæ are detached, the exact relation of one to the other is uncertain. Three of the teeth of the right maxilla have been cracked and the fragments pushed apart during fossilization, but otherwise they are practically perfect. ⅔ natural size.

When I sent off the first notice of the discovery a few days after the find was made (see NATURE, Sept. 19, p. 486), only the upper part of the skull and the right maxilla were known. In the stone on the left side of the left orbit I later discovered the nearly perfect left maxilla, with both premolars and the 1st and 2nd molars in perfect condition and the sockets of the incisors and canine. The 3rd molar is probably also present but it cannot be displayed without destroying an important part of the skull.

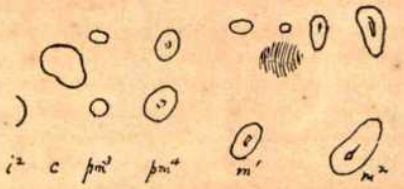

FIG. 2. Irregular section across the roots of some of the teeth of the right maxilla of *Australopithecus transvaalensis* Broom; the little shaded area between the roots of m^1 is part of the floor of the maxillary antrum. Note the remarkable degree to which the roots of the molars spread. Natural size.

The premolars and 1st molars are so remarkably human-like that there is scarcely a doubt that had they been found without the skull they would have been held by most to be human. They bear no close resemblance to the corresponding teeth in the chimpanzee. Each premolar has only two roots.

The canines are relatively small, and the incisors large. Perhaps the most striking character is the fact that the canine and the 2nd incisor are in contact as in man, and not with a gap between them as in living anthropoids.

It is unnecessary at present to discuss in detail the various features of the dentition, but Figs. 1 and 2 are sufficient to show that the Sterkfontein ape at least is not a chimpanzee, and that it approaches man in quite a number of characters.

A New Upper Triassic Fossil Insect Bed in Queensland

SOME four years ago, two members of the staff of the Queensland Geological Survey, Messrs. Owen Jones and Denmead, picked up at Mount Crosby, some thirty miles inland from Brisbane, two finely preserved cockroach tegmina on pieces of dark brown shale. These were sent to me for description, and proved to belong to two new species of the genus *Triassoblatta*, originally described from the Rhaetic of Ipswich, Queensland (a locality about seven miles from Mount Crosby).

On my visit to Queensland in June 1936, members of the University of Queensland and of the Geological Survey, including Mr. Denmead, accompanied me to this locality. The original bed of shale, from which the cockroach tegmina came, was found without much difficulty. It appears to represent the mud deposit of the stream-bed of an ancient river which flowed sluggishly between high banks of older Brisbane Tuff. The age of the beds is definitely older than that of the Ipswich fossil insect beds, and may be placed with considerable certainty as Upper Triassic. The insect-bearing shales lie beneath a loose conglomerate, and are only about ten inches thick. Insect remains are abundant but mostly fragmentary, and are found in association with the following plants: *Schizoneura*, *Thinnfeldia*, *Baiera*, *Voltzia* and a Cycadophyte. The remains of the genus *Triassoblatta* include fore and hind wings, heads, pronota, thoracic and abdominal sclerites, all evidently having been separated by gentle maceration in the stream bed and fossilized separately. They total about half the whole number of fossil insects so far discovered.

---

* Published by permission of the Trustees, Transvaal Museum, Pretoria.

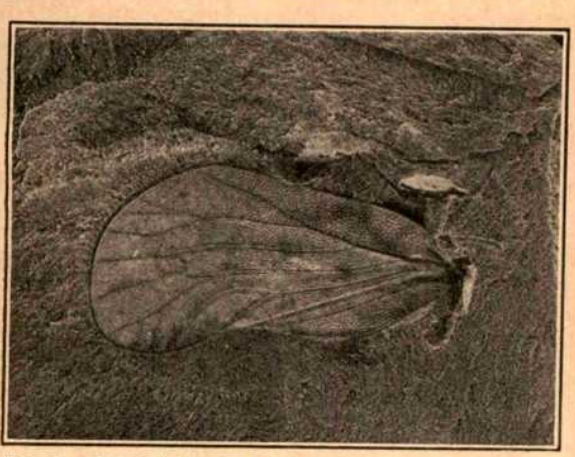

FIG. 1. Complete tegmen of a specialized Scytinopterid type (order Homoptera, division Auchinorrhyncha) in process of becoming a true Heteropterous type. Length 12 mm.; Upper Triassic of Mount Crosby, Queensland. Photo by Walter James.

The dominant order in families, genera and species is the Homoptera, with the following groups: Prosbolidæ, Scytinopteridæ, Fulgoroidea, Jassoidea and Psylloidea. The photograph (Fig. 1) shows the most remarkable of a number of perfectly preserved homopterous tegmina, in the shape of one which appears to be turning from a Scytinopterid type into a true Heteropteron. This is the first clear indication from palæontology of the probable mode of origin of the Heteroptera from the older Homoptera.

Next in importance are the Coleoptera, represented by elytra, heads and bodies. They are all small types, the largest being about 8 mm. in length (elytron), and the smallest only about 1 mm. long and therefore the tiniest fossil insect so far discovered. The Ipswich genus *Ademosyne* is well represented, but the beetle fauna is nothing like so abundant as at Ipswich.

Next in point of interest come the Trichoptera, with three entirely new types, two being perfect forewings. These are easily the oldest known Trichoptera, and represent almost perfectly the archetypic wing already postulated in my previous papers.

The older order Paratrichoptera is only represented by a single tiny wing, which could be classed as a Dipteron were it not for the form of its anal area.

A magnificent wing, practically perfect, introduces the true order Diptera as a member of this fauna. It has the general form of a Tipulid, with three-branched radial sector, but the anal area is of Tanyderid form, with only a single anal vein. As usual, the action of the water on this wing has caused considerable longitudinal rucking.

Some fine mecopterous types are present, including the genus *Mesochorista*, originally described from Ipswich, and a fine type ancestral to *Archipanorpa* and apparently also closely related to the Orthophlebiidæ of the Lias in the northern hemisphere.

True Neuroptera are represented by three new types, one being a perfect wing allied to the Berothidæ. Other orders, unfortunately so far only represented by fragmentary wings, are the Odonata and Orthoptera.

A total of more than two hundred specimens has now been obtained as a result of breaking up less than a cubic yard of shale. No less than fourteen specimens were found by splitting one small piece about four inches long by three inches wide and about an inch thick. Unfortunately, the amount of suitable material available is strictly limited, but the discovery promises to be one of the most interesting of recent years, and helps to fill the gap between the Upper Permian and the Rhætic.

A monograph on the above insect fauna is now in course of preparation.

The Gondwana Affinities of the Angara Flora in the Light of Geological Evidence

THE late Palæozoic flora of northern Russia and Siberia has long been known to include a certain element remarkable for its suspected affinities with the *Glossopteris* flora[1]. Prof. Zalessky, to whom much of our recent knowledge of the Angara flora is due, has been the chief exponent of the Gondwana affinities of the northern flora[2]. Prof. Halle believes (probably with some justice) that these affinities have been somewhat over-emphasized. But no one, so far as I know, has denied that some striking resemblances exist, and the view has been repeatedly expressed that there must have been some means of communication between the Gondwana and Angara continents.

The idea of a northward migration of plants from Gondwanaland is now forty years old, and has been advocated by many palæobotanists including Seward, Zalessky, Newell Arber, Grabau and myself[3]. In 1918, Zalessky suggested that either the two continents were once connected by an isthmus, or else some other means of intermigration, such as a dense group of islands, must have existed. Grabau[4] wrote: "It is possible that this northward migration of the Gondwana flora occurred during Carboniferous (pre-Permian) time, though so far as we know there were no direct land connections". The most obvious, if not the only, route seemed to me to be that through Kashmir[5], and I even suggested that possibly Kashmir was only a southern outpost of Angaraland. But data from the critical region between Kashmir and the known southern limit of the Angara flora were lacking, and are still awaited.

D. N. Wadia's brilliant work on the syntaxis of the north-west Himalaya[6] seemed at first to suggest that the marine barrier of the Himalayan geosyncline was too complete to allow migration of land plants to the northern continent. Nevertheless, the resemblance between some of the northern and southern types seemed to me too striking to be due to chance. I therefore wrote in a recent paper[7] as follows: "In the face of these considerations, Zalessky's hypothesis of a connecting isthmus or a chain of islands across the Tethys does seem bold, but then the Gondwana resemblances of the Angara flora, which, I believe, are undeniable though they may have been exaggerated, must be explained by an indirect route, still to be discovered."

Unfortunately for us palæobotanists, at a congress in Heerlen (September 11, 1935) when these matters were discussed in a geological atmosphere, we could not induce Mr. Wadia, who was present, to take part in the discussion. For had he done so, we would have learned, there and then, that he had already found this much-needed evidence of a means of communication with the north, during his recent field work in north-west Kashmir and Hazara[8]. According to Wadia, until as late as the end of the Middle Carboniferous, a continuous land bridge must have stretched from the Punjab as far as the Pamir plateau and possibly beyond. This is proved by the occurrence of a well-marked regional unconformity between the marine Dogra slates, which are probably of Cambrian age, and the overlying agglomeratic slate, regarded as not older than Upper Carboniferous. The long period of time from the Cambrian until at least the end of the Middle Carboniferous was therefore a land period* in this area. This land bridge, as stated, must have stretched at least as far as the Pamir plateau. What the conditions were farther north we shall only know from the work of our Russian colleagues: quite possibly the land bridge was unbroken as far as the northern continent.

Wadia further states that even during Upper Carboniferous and Permian times, the Kashmir portion of the Tethys must have been studded with an archipelago of volcanic islands, which may well have permitted some intercourse for land plants between India and the north. Proof of this is to be found in the presence of carbonaceous matter as well as recognizable impressions of Gondwana plants at six or seven localities in the Permo-Carboniferous tuffs so extensively developed in this region.

I confess that, not being a geologist, I had at first failed to appreciate the full implications of this work, although I had read it early in 1935. Mr. Wadia, in his turn, told me recently that he had not at first realized how important for palæobotanists was the evidence that he had found. Zalessky's idea of a possible archipelago in the Tethys, which may have served as stepping-stones for terrestrial forms of life migrating north, thus emerges as a prophetic utterance.

It remains to add that it is at Mr. Wadia's suggestion that I am writing the present note, which has been read by him. If conditions permit, we hope to present the whole evidence, from our respective points of view, before the International Geological Congress to be held in Moscow next year. On that occasion I also hope to be able to bring with me typical specimens of Indian Lower Gondwana plants for a direct comparison, now more urgent than ever, with the Gondwanoid members of the northern flora.

Early Chinese Glass from Pre-Han to T'ang Times

IN a previous letter[1], Beck and Seligman described the analysis of a large ornamental glass "eye-bead" from the Han Chün graves near old Lo Yang, dating back to the second half of the third century B.C. or perhaps even earlier. This bead had the surprisingly high specific gravity of 3·57, and proved to be essentially a lead-barium silicate, with small amounts of soda, lime, alumina, etc. Prompted by this unexpected result, we have now extended our examination to a series of thirty-two specimens of Chinese glass, covering some twelve centuries, pre-Han and Han (*c.* 250 B.C., or earlier – A.D. 220) and T'ang (A.D. 618–907). Within these broad limits, there is little reasonable doubt as to the correct dating of the pre-Han and Han specimens. It is more difficult to be certain of the T'ang; perhaps all the specimens so attributed may be of this period, and some certainly are. As most of the specimens were of considerable value, only minute samples could be removed for analysis. The work was carried out spectrographically, and though accurately qualitative, no attempt was made to place it on more than an approximately quantitative basis.

While it is obviously not permissible to generalize too freely from such a limited number of specimens, a broad general fact emerges—namely, that in passing from pre-Han to T'ang times, Chinese glass tends to change from a lead-barium silicate type (so far unique) to a lead-soda-lime silicate type and to the more common soda-lime silicate type. The results may be grouped as follows:

(1) Twenty-three specimens of pre-Han and Han glass were examined, including eleven "eye-beads", more or less resembling the type originally described. Twenty belonged essentially to the system $PbO : BaO : SiO_2$, with small amounts of soda, lime, etc.; the lead was usually accompanied by tin and silver, and often by traces of bismuth and antimony. The specific gravity ranged from 3·25 to 5·25. The remaining three specimens contained no barium.

(2) Nine specimens of T'ang glass were examined. Seven were essentially soda-lime silicates, and two lead-soda-lime silicates. No barium was found, save a trace in three specimens.

An extended statement of the spectrographic analyses summarized in this preliminary note will be published by one of us (P. D. R.) in "Technical Studies in the Field of the Fine Arts", together with analyses of a number of intermediate specimens, which are less definitely dated but may be thought to range from the post-Han period to that of the Wei, say, third to sixth centuries A.D.

A Cosmic Ray Burst at a Depth equivalent to 800 m. of Water

WE have recently made measurements of cosmic ray intensities in the Simidu tunnel of the Government Railways of Japan. The measurements were carried out at different positions along its length of 9·7 km., in order to find the penetration of cosmic rays through various thicknesses of rocks, which consist mainly of diolite, the average density being probably 2·8. The measuring apparatus was the Neher electroscope[1] with which Dr. Millikan kindly supplied us. The ionization chamber of diameter 15 cm. was covered with 11 cm. of lead and was left at each place for about 24 hours. The vertical thickness of rocks varied from 1,230 m. to 120 m., corresponding to about 3,400 m. and 340 m. of water-equivalent respectively.

The results of the measurements are given in the accompanying table. The minimum thickness of rocks overhead was calculated from the contour lines of a map and is naturally not exact. The ionization values were calculated according to the constant of the instrument determined and communicated to us by Dr. Neher. They should be taken as relative values rather than absolute, because the difference in the surrounding conditions might have caused a minute change in the constant of the instrument.

Vertical thickness of rocks (m.)	120	175	220	325*	650	1230
Its water-equivalent (m.)	340	490	620	910	1800	3400
Minimum thickness of rocks (m.)	120	175	175	290	540	880
Its water-equivalent (m.)	340	490	490	810	1500	2500
Ions/cm.^{3}/sec./atm. (Cosmic rays + residual)	0·230 ± 0·001	0·223 ± 0 003	0·224 ± 0·003	0 222 ± 0·004	0·221 ± 0·002	0·220 ± 0 004

* A burst of about 10^7 ions was observed at this position.

Unfortunately, the residual ionization which Dr. Neher determined by going 70 m. underground is rather large (0·23 ions/cm.^{3}/sec./atm.) and the instrument is not suited for the present purpose. From the decrease of ionization with depth shown in the table we see the indication of the penetration of cosmic rays through much thicker layers of matter than has hitherto been observed[2]. The fluctuation of the ionization, however, is larger than the difference of ionization between the succeeding depths, and no definite inference in this regard can be made at present.

One conclusion, however, which we can draw from our results, is that the cosmic rays can definitely pass through more than 800 m. of water, and probably go much deeper. We observed, for example, a burst of the size of about 10^7 ions at a vertical depth of 325 m. (min. depth 290 m.), corresponding to a much greater penetration than has hitherto been directly observed. Both Kolhorster and Corlin[3] made measurements with an ionization chamber down to 800 m. water-equivalent underground. The cosmic ray intensity at this point was tentatively assumed to be zero. From the above results, however, we see that there still remains a very small part even at this depth.

Our measurements were made possible by the courtesy of the Bureau of Maintenance of the Japanese Government Railways, and our thanks are especially due to Mr. H. Asonuma and Dr. T. Watanabe of the Department of Railways, as well as Prof. M. Ishimoto of the Imperial University, Tokyo, for their interest in this work, and to Mr. Minamide and others at Minakami Station who offered us much assistance.

Radioactive Isotopes of Nickel and Copper

IT has been shown by Fermi and co-workers[1] and by Bjerge and Westcott[2] that the activity induced in zinc through neutron bombardment is due to an isotope of copper. Considering the well-known possibilities of the formation of active substances by a neutron bombardment, it is evident that the possibility of forming an active isotope of nickel is implied. Now, by means of an apparatus formerly described[3], the formation of active nickel from zinc irradiated with neutrons has been actually shown.

The experiments were carried out with metallic zinc powder. After activation, it was dissolved in nitric acid and a trace of cupric oxide and of nickel sulphate was added. The copper was precipitated from the acid solution by means of hydrogen sulphide. After filtration, ammonium chloride in excess was added to the filtrate, next dimethylglyoxime was added, and finally the acid solution was made alkaline by the addition of ammonium hydroxide. The red precipitate was ignited and placed in a counter in a manner formerly described[4]. The activity decayed with a period of nearly 100 minutes. McLennan and others[5] have found a period of 100 minutes produced by slow neutrons in metallic zinc. Perhaps this is the same activity as that mentioned here. Rotblat[6] and Naidu[7], however, found a period for nickel formed by means of neutron irradiation of nickel to be 3 hours. These results may indicate the possibility of the existence of two active isotopes of nickel—possibly $^{63}_{28}$Ni and $^{65}_{28}$Ni.

The period of the active copper has also been measured. The copper sulphide was dissolved in nitric acid and transformed to cupric oxide. The period of this product was measured and found to be 17 hours. This result is not in accord with the results of Fermi and of Bjerge and Westcott, who found 10 hours and 6 hours respectively. Special care was taken in the measurements during the first twenty hours to find, if possible, a shorter period, but the decay curves only gave the 17-hour period. Van Voorhis[8] has reported an activity produced in copper by deuteron bombardment, supposed to be due to an isotope $^{64}_{29}$Cu, with a period of 12·8 hours, emitting both positrons and electrons. It seems difficult at present to reconcile these observations, apparently giving four different decay periods for the same isotope. As the experimental method only allows detection of active products with fairly long periods, the 5-minute period of copper was not found.

The number of particles counted from the nickel is only one tenth of that from the same amount of copper.

Attempts to isolate active chlorine from irradiated potassium gave negative results. This may be due to the possibility that it is not $^{36}_{17}$Cl, but $^{38}_{17}$Cl which is the bearer of the chlorine activity already known.

Evidence for the Expulsion of Two Neutrons from Copper and Zinc by One Fast Neutron

COPPER and zinc were bombarded with neutrons from different sources. The results are represented in the following table:

Source of neutrons	Periods	
	Copper	Zinc
$^2H + ^2H$	6 m. (weak)	No activity
$^2H + ^2H + P$ $Be + ^2H + P$	6 m.	60 m
$Be + ^2H$	6 m. (weak)	No activity
$Li + ^2H$	10·5 ± 0·5 m.	6 m. 60 m.
$Li + ^2H + Ag + Cd$	10·5 ± 0·5 m.	6 m. 60 m.

P means that paraffin was used to slow down the neutrons. Ag + Cd means that a sheet of 0·2 mm. silver and one of 0·2 mm. cadmium were placed between source and bombarded material in order to stop slow neutrons.

The 6-minute period of copper most probably corresponds to the 5-minute period reported by Fermi and his collaborators[1]. The 10·5-minute period appears with the fast neutrons from ($Li + ^2H$) only. An initial activity of 1,200 impulses per minute was measured. An activity of about 11 minutes observed in cobalt bombarded with slow neutrons and in nickel with fast neutrons (which may be the same as the 20-minute period reported by Rotblat[2]) might lead to the assumption that an active cobalt isotope is produced here. We found, however, that this assumption is not justified.

The 60-minute period of zinc induced by slow neutrons probably corresponds to the 100-minute period reported by McLennan, Grimmet and Read[3], the 6-minute period to that reported by Fermi and his collaborators[1].

The same 60-minute period appears, however, with the fast neutrons from the ($Li + ^2H + Ag + Cd$) source, and not with those from the ($^2H + ^2H$) or ($Be + ^2H$) source, which excludes the possibility of ascribing this activity to the action of slow neutrons; it indicates that neutrons of considerable energy are essential here.

A chemical separation of the radioactive substances was attempted by Mr. R. W. P. de Vries. As to copper (10·5-minute period): cobalt and nickel precipitated in different ways were found to be inactive. Copper precipitated electrolytically was active. As to zinc (60-minute period obtained with fast neutrons): precipitated nickel was inactive. Copper showed a 6-minute and a 10–12 hour period, as was to be expected. Zinc precipitated electrolytically from the solution showed the 60-minute period. Both activities must therefore be ascribed to isotopes of the irradiated elements.

An investigation of the particles emitted by copper (10·5-minute period) by means of magnetic deflection *in vacuo* and a Geiger-Müller counter proved these to be positrons. A period of about 10 minutes was found for these deflected positrons. The intensity of the 60-minute period of zinc was too small to observe the deflected particles with certainty.

From these data we may infer that the following reactions take place with fast neutrons:

$$^{63}Cu + {}^1n \rightarrow {}^{62}Cu + 2\,{}^1n \qquad {}^{62}Cu \rightarrow {}^{62}Ni + e^+$$
$$^{66}Zn + {}^1n \rightarrow {}^{65}Zn + 2\,{}^1n \qquad {}^{65}Zn \rightarrow {}^{65}Cu + e^+$$

We found the same zinc isotope to be formed by capture of a slow neutron:

$$^{64}Zn + {}^1n \rightarrow {}^{65}Zn.$$

The possibility of the type of reaction described was discussed by Fermi[4] but up to the present it had not been observed with certainty (cf. L. Meitner and O. Hahn[5] and Johnson and Hamblin[6]).

Further details and a description of our apparatus will appear elsewhere.

Thermal Properties of Helium, Hydrogen and Deuterium

IT has been shown by F. Simon[1] and F. London[2] that the abnormally large specific volume and compressibility of helium and hydrogen can be understood by considering the influence of the zero point motion. Clusius and Bartholomé[3] pointed out that this zero point motion is also responsible for the fact that the specific heat of hydrogen is nearly equal to that of deuterium. They remarked that it is no longer legitimate here to represent the potential energy as a quadratic function of the deviations of the particles from their equilibrium positions.

As at low temperatures only long heat waves, which are harmonic, contribute to the specific heat, and the frequencies of these waves are determined by the velocity of sound, the specific heat near the absolute zero can be calculated if the velocity of sound is known.

It is possible to derive a 'Schrödinger equation' for a crystal deformed by a long wave. The deformation energy, derived with the help of this equation, contains not only a change in the potential energy but also in the kinetic energy. An expression for θ is obtained in which the two effects are separated:

$$\theta^2 = \frac{1}{2\pi^2 l^2}\,\frac{h^2}{mk^2}\left[\frac{s}{2} + \frac{\pi^2 h^2}{2^8 m l^4}\right],$$

where m is the mass of the particle, s the second derivative of the molecular field at a lattice point and l is a length which is equal to or smaller than $a - \sigma$ (a is distance between nearest neighbours, σ is molecular diameter).

Taking $l = a - \sigma$, and omitting s (which means that the molecules are replaced by hard spheres) the following results are obtained:

	Mol vol.	σ	l	θ calc.	θ exp. (0° K.)
He	19·88	2·35	1·24	29 2	34·0 [4]
	19 32	,,	1·21	30·8	36·0 [4]

The rather large deviation shown by deuterium may be due to the fact that it is not permissible to omit s in this case, and the value of l is only an upper limit.

Some conclusions about the thermal expansion can also be deduced by this formula. According to Debye's theory[6], the thermal expansion contains the factor $-\delta\theta/\delta V$. For increasing volume, s becomes negative and then becomes zero. At very small densities it may therefore give a positive contribution in $\delta\theta/\delta V$. So the thermal expansion might become negative for very small densities.

Although the formula only holds for crystals, this might still be an indication of how the negative expansion coefficient of 'liquid' helium II is to be explained.

A detailed account will be published in *Physica*. My thanks are due to Dr. A. Michels for stimulating discussions.

Electrification of a Roof during a Thunderstorm

A LETTER from my daughter in Jamaica refers to her house being affected electrically in a curious manner. She was sitting on the verandah during a thunderstorm when she heard "a funny sound like the buzzing of a bumble-bee", and saw that the verandah gutter was emitting sparks and smoke. Running to the kitchen to get a bucket of water, she found the legs of the stove, where they rested on the stone floor, spluttering sparks. She threw a bucket of water on them, and in doing so "got quite a bad shock and the bucket was torn out of my hands". On returning to the verandah, the gutter was still emitting sparks.

The explanation of this affair appears—from my knowledge of the house—to be as follows. The roof—its ridge about 25 ft. above the ground—is of galvanized iron, and is insulated from 'earth' except via the kitchen stove funnel. The guttering is fastened to wooden verandah pillars and normally is not in contact with the roof. The single down-pipe of the guttering leads to a water tank and presumably is earthed.

I imagine that what occurred is this: somehow the partially insulated roof became charged as one plate of a condenser, and the charge, being insufficient to break through the resistance to earth in one discharge, leaked away gradually via the weak contact of the stove legs with the floor and also via the small gap between the roof and the gutter. The shock my daughter got was obviously due to the thrown water forming another channel for discharge via the bucket and herself.

Points from Foregoing Letters

DR. BROOM has now prepared a description, with diagrams, of teeth belonging to the fossil skull, *Australopithecus transvaalensis*, described by him in NATURE of September 19, p. 486. It will be recalled that the skull was found at Sterkfontein, Transvaal, and is of presumably Upper Pleistocene age. The teeth differ from those of the chimpanzee and resemble those of man in many respects.

A photograph of a fossil wing-cover of an insect from the Upper Triassic of Queensland, showing transition from characters of the order Homoptera to those of Heteroptera, is submitted by Dr. R. J. Tillyard. The bed from which it was obtained is rich in insects; some two hundred specimens belonging to various orders (Homoptera, Coleoptera, Trichoptera, etc.) have been found in less than a cubic yard of shale.

A continuous land-bridge must have stretched in Permian to Middle Carboniferous times from the Gondwanaland (the Palæozoic continent which spanned the South Atlantic and Indian Oceans) northwards through the Punjab as far as the Pamir Plateau and possibly beyond. Commenting on the evidence for this view, supplied by the investigations of D. N. Wadia in the Himalaya, Prof. B. Sahni points out its importance to the old hypothesis of a land connexion between Gondwanaland in the south and Angaraland (which included a great part of eastern Siberia) in the north across the Thetis Sea (of which the Mediterranean is a remnant).

Chemical analysis of early Chinese glass indicates that in the period from pre-Han (before A.D. 220) to T'ang times (A.D. 618) Chinese glass tends to change from lead-barium silicate type to the more common soda-lime silicate type. The investigation was carried out spectrographically on minute samples by Prof. C. G. Seligman, Dr. P. D. Ritchie and H. C. Beck.

Dr. Y. Nishina and C. Ishii have recently made measurements of cosmic ray intensities in a railway tunnel under a vertical thickness of rock (diolite) varying from 1,230 m. to 120 m., water-equivalent about 3,400 m. and 340 m. respectively. At a vertical thickness of 325 m. (minimum thickness 290 m.) a burst of 10^7 ions was observed, which proves the presence of cosmic rays after passing through rock the absorption of which is equivalent to that of more than 800 m. of water.

The chemical identification of radioactive nickel, of nearly 100 minutes period, prepared by irradiation of zinc with neutrons, is described by Dr. C. B. Madsen. Radioactive copper was also obtained, with a period of 17 hours. Bombarding copper and zinc with neutrons, according to F. A. Heyn, leads to expulsion of other neutrons and formation of radioactive isotopes of the elements irradiated.

An equation for calculating specific heats at very low temperatures (near the absolute zero), if the velocity of sound is known, is given by A. Bijl. In the case of helium and hydrogen, the calculated values agree with those experimentally observed, but in the case of heavy hydrogen there is a wide discrepancy. This, the author considers, may be due to the fact that the simplifying assumption—that molecules behave like hard spheres—is not permissible in the case of heavy hydrogen.

Research Items

Physical Characters of the Cook Islanders

To a series of monographs on the physical characters of the native populations of Polynesia, Dr. H. L. Shapiro and Dr. P. H. Buck (Te Rangi Hiroa) have added a study of the Cook Islanders, based on material collected by Dr. Buck in 1926 and 1929 (*Mem. Bernice P. Bishop Museum*, 12, No. 1). The process of disintegration has not gone so far in Cook Islands as in other parts of Polynesia, and it is still possible to find there a representative example of true Polynesians. Although strictly speaking the Cook Islands are limited to six, three others, Manihiki, Rakahanga and Tongareva are included. Of the 913 individuals examined, a number were rejected as unsuitable, and the records here studied are derived from 804 individuals, of whom 551 are males and 253 females. Ten measurements and twenty observations were taken. The characteristic features show that the Cook Islanders are akin to other Polynesian groups. Tall, robust, and well developed, they show a typical tendency to brachycephaly, with a massive face and characteristic combination of broad bizygomatic diameters with high narrow foreheads. The nose is large and fleshy and the lips full. In complexion they are moderately brown-skinned with dark, straight, or wavy hair, which, though luxuriant on the head, is only sparsely developed on the body and face. The eyes are full and dark-brown, and the epicanthus is usually absent. The archipelagic uniformity which is characteristic of other parts of Polynesia, with one exception, is completely lacking here. The exception is the resemblance between Manihiki and Rakahanga. Certain characters, however, bind the islanders into a homogeneous group, while in others, such as nose height, face height, head length and span, the islanders are differentiated one from another. Two distinct types, however, can be established with several intergrades, the differences to be allotted to Central. Western and Maori strains.

Proficiency and Psychological Tests

REPORT No. 74 of the Industrial Health Research Board, by E. Farmer and E. G. Chambers, is a study of the prognostic value of some psychological tests. In all, 2,731 men from fourteen occupational groups were tested with a number of psychological tests, and the data were examined to see to what degree proficiency at the tests was related to proficiency at the different occupations. Statistical treatment of the results showed that the psychological tests given to adolescents did have prognostic value in the skilled groups, but that they were of no diagnostic value for proficiency in the unskilled groups. There was also no evidence to show that psychological tests can afford a measure of the factors involved in the proficiency of those already proficient. The report is extremely valuable, not only for its positive conclusions but also because it shows the very great complexity both of the processes involved in proficiency and in the interrelation of the various psychological functions. Vocational selection is an infinitely more difficult problem than some enthusiasts for testing realize.

Birds of Bay Islands, Spanish Honduras

"LAS ISLAS DE LA BAHIA" form a chain of islands in the Caribbean Sea, off the north coast of Honduras. They are little known, and have a very limited fauna, land shells being particularly scarce. James Bond has described the resident birds of the islands, 43 species or subspecies, five of the latter being new to science (*Proc. Acad. Nat. Sci. Philadelphia*, 88, 353; 1936). The resident bird fauna is fundamentally of Central American type, and the island chain must be looked upon as the tops of a submerged mountain range, which through isolation from the mainland have retained a number of Central American species. These relict forms have entirely or almost disappeared from Central America proper, but they appear, again as relicts, on islands off the coast of Yucatan.

Reproduction in the Chimpanzee

THERE are about twenty published records of the birth of chimpanzees in captivity, but in none of these cases has the whole process been described in the full detail which is given in a recent paper by J. H. Elder and R. M. Yerkes (*Proc. Roy. Soc.*, B, 120, 409; 1936). This paper reports fifteen births (one of them twins) which have occurred during the last six years in the Yale Laboratories of Primate Biology. Fertilization, pregnancy, parturition and the puerperium are fully described. Impregnation occurs about, or slightly after, the midpoint of the 35-day sexual cycle. The average duration of pregnancy was 236 days—about 30 days shorter than in man. Menstrual bleeding does not commonly recur after conception. Almost without exception, the chimpanzee female during pregnancy and nursing is much more gentle, friendly, dependable and easily handled than at other times.

Genetical Constitution of *Drosophila pseudo-obscura*

LIGHT is thrown on the relationships of species by a comparison of their mutations. Mr. H. P. Donald (*J. Genetics*, 33, No. 1) has investigated the forty-five known mutations of *Drosophila pseudo-obscura* in comparison with those of *D. melanogaster*, and gives revised linkage maps for its five pairs of chromosomes. A number of the mutants are similar to those of *D. melanogaster*; for example, the autosomal types bithorax, glass, stubble, pink, cross-veinless and jaunty, and the sex-linked mutations known as pointed (= beaded), yellow, scutellar, white, singed, vermilion and miniature. Linkage maps of the two species, connecting genes which are supposed to be homologous, indicate that various rearrangements of the genetic material have taken place, and that these have been intrachromosomal more frequently than interchromosomal. Considerable homology is indicated between corresponding chromosomes or whole arms of chromosomes in the two species. Despite a number of translocations involving changes in the positions of one or more genes, the loci involved appear to have retained largely the same phenotypic effects, variability and mutability as before.

Radioactive Elements in Plants

THE continued interest in the relation of radioactivity to plant growth focuses attention on the paucity of information available as to the presence of radioactive elements in plants. K. Kunasheva and B. Brunowsky, of the Biogeochemical Laboratory of the Academy of Sciences at Moscow, who have already published work dealing with the presence of elements of the thorium series in duckweed, have reported in a letter to the Editor the results of quantitative determinations of uranium in the same species. They find the uranium content to be $9 \cdot 5 \times 10^{-5}$ per cent. By the same method the radium content was found to be $2 \cdot 38 \times 10^{-11}$ per cent. On the basis of these figures, the ratio Ra : U for duckweed is calculated as $2 \cdot 7 \times 10^{-7}$, that is, within the limits of error in measurements, uranium is in equilibrium with radium. Details of the method and results of the measurements are to be published in a forthcoming issue of the *Proceedings of the Biogeochemical Laboratory of the Academy of Sciences*.

A New Genus of Mesembryanthemum

The late Dr. N. E. Brown left a manuscript note of six species of shrubby South African mesembryanthemums. He included these in a new genus, *Mestoklema* (Gr. *Mestos*, full, *klema*, a small branch), and full descriptions of the species appear in the *Gardeners' Chronicle* of August 29. *Mestoklema* is allied to the older genus *Delosperma*, but differs in its peculiar branched habit, the very small flowers, the persistent, hardened, subspinose cymes, and the closed cells of the capsule, which are provided with cell wings.

The South Sandwich Trench

To the north and east of the South Sandwich Islands in the South Atlantic on the edge of the Weddell Sea, the *Meteor*, and later *Discovery II*, took some unexpectedly deep soundings exceeding seven thousand metres. This area was further sounded in the most recent cruise of *Discovery II* and is provisionally mapped in a paper by Dr. N. A. Mackintosh on "The Third Commission of the R.S.S. Discovery II" in the *Geographical Journal* of October. The trench seems to extend in an arc about a hundred miles to the east of the line of volcanic peaks which constitute the group of South Sandwich Islands. On the north it ends in about lat. 55° S., and in its northern part it is widest and deepest, falling to below eight thousand metres. To the south it narrows to a cleft of more than seven thousand metres, less than ten miles wide in its deepest parts. This remarkable cleft has not yet been traced south of about lat. 61° S., where it seems to curve towards the west, south of the ridge joining the South Sandwich and South Orkney Islands.

'Polaroid'

DEMONSTRATIONS of some technical uses of the new polarizing material 'Polaroid' are being given by appointment with Messrs. Polaroid Products, Ltd., 39 Lombard Street, E.C.3 (Telephone, Mansion House 2997). This firm is the representative agent in Great Britain of the American manufacturers of the polarizing film described by Prof. A. F. C. Pollard in NATURE of August 22 (p. 311) and now named the International Polaroid Corporation, New Jersey, U.S.A., with its laboratories in Boston. The film, which formerly consisted of nitrocellulose, but now consists of the less inflammable cellulose acetate, contains sub-microscopic crystals of herapathite with their optic axes oriented in one direction parallel to one another, and is made in the two grades designated Types I and II. Type I is intended for use in optical systems and instruments, whereas Type II is intended for use over light sources when plane polarized illumination is required. Type I may be obtained clear or dyed in various colours. Type II is not optically clear, but polarizes light just as efficiently as Type I and is cemented to one side of glass sheet. Messrs. Polaroid Products, Ltd., supply Type I film, cemented between glass plates of optical quality sufficiently good for most purposes and mounted in bakelite rims with an aperture of 4 cm. Disks, ¼–4 in. diameter, and squares of the same dimensions, with the film cemented to one side of the glass only can also be supplied immediately. The American concern is now manufacturing film 2–2½ ft. wide, and, we are informed, will supply 'Polaroid' in production quantities in the near future. Amongst the technical applications of 'Polaroid' to be seen at the demonstration there is the elimination of glare by motor-car headlights, a very striking and beautiful stereoscopic cinema projection in natural colours, a large apertured stereoscope which can be viewed by several people at the same time, a strain viewer and some effects with colourless 'Cellophane' cut out to form pictures which in polarized light appear in a variety of interference colours. In addition, a lamp is arranged to give strong polarized illumination so that the texture of the skin may be examined by the aid of a 'Polaroid' screen.

A Fairthorne–Salt Mathematical Film

A CINEMA film to show the qualitative properties of the differential equation $\ddot{x} + x = 0$ has been produced by R. A. Fairthorne and B. G. D. Salt and can be obtained from the former at Kirk Michael, Hillfield Road, Farnborough, Hants. It shows two disks of variable radius, revolving at constant speed. The radius of one represents the acceleration $\ddot{x}$, so the length of a string unrolled from it represents the velocity $\dot{x}$. The radius of the second disk is equal to the length of this string, and so represents this velocity, and the length of a string unrolled from it represents the distance x. By arranging that the length of this second string, taken in a certain direction, is numerically equal to the radius of the first disk, we get the differential equation. This arrangement may be regarded as embodying the fundamental ideas of the differential analysers used by Dr. Bush at Massachusetts Institute of Technology or Prof. D. R. Hartree at the University of Manchester. The film can be obtained on 35 mm., 16 mm. or 9·5 mm. stock. The methods used can be extended to other differential equations, as was explained in a paper by Mr. Fairthorne read before the International Congress of Mathematics at Oslo last July.

ERRATUM.—In the summary prepared for NATURE of Dr. I. V. Newman's paper before the Linnean Society of New South Wales on the angiospermic carpel (NATURE, August 1, p. 209), the third conclusion, that "the legume is not a foliar structure", is incorrect. It should read "the evidence is compatible with the legume being a foliar structure".

The Second International Cancer Congress

THE Second International Cancer Congress, held at Brussels under the auspices of L'Union Internationale contre le Cancer, terminated on September 28. Between three and four hundred surgeons, physicians, radiologists and research workers, drawn from forty-seven different countries, were in attendance, and were welcomed by M. Lerat, president of the Congress; by M. Justin Godart, president of L'Union Internationale contre le Cancer; and by M. Vandervelde, (Belgian) Minister of Health, in the presence of H.M. The King of the Belgians.

Great Britain was officially represented by Dr. W. Cramer, Col. A. B. Smallman, Mr. Sampson Handley, Mr. J. J. Shaw, and Mr. Cecil Rowntree. There was also a large group of workers from the great research centres, which included Dr. W. E. Gye, Prof. E. L. Kennaway, Prof. J. W. Cook, Dr. R. D. Passey, Prof. Mathew Stewart, Dr. Dorothy Russell, Dr. P. D. Peacock, Dr. Donaldson, and Mr. Stanford Cade.

The Belgian Committee, to whom the organization of the Congress had been entrusted by the Union Internationale, by a wealth of private and public hospitality did much to establish a degree of intimacy between the nationals of so many diverse countries, and added greatly to the success of the Congress.

Among the more notable official occasions was a reception by the Prime Minister and Mme. van Zeeland held at the beautiful Musée Cinquantenaire; and a banquet at which speeches were made by representatives of Germany, France, Great Britain, Italy, Spain, Greece and Sweden expressing their appreciation of the great scientific and social success of the Congress. During the latter, one delegate felt that song was the only suitable medium with which to express his feelings, and brought down the house with his delightful rendering of "Qui ne sait boire, ne sait rien".

But perhaps the most interesting event—in any event so far as the delegates from the British Empire were concerned—was the reception on the last evening at the Fondation Universitaire, when the opportunity was taken to present to Profs. Kennaway and Cook the prize award of the Union Internationale. The allocation of this prize to the two English research workers was unanimously voted at a meeting of the Council of the Union. It consists of a sum of money and a quantity of radium, generously placed at the disposal of the Union Internationale by the Union Minière [see NATURE, Oct. 3, p. 579].

In addition to a large number of independent papers, thirty-five official reports were presented. All the different aspects of the cancer problem came under consideration, and the subjects ranged from the demonstration of micro-puncture of cells by ultra-violet rays, to the provision of hospital accommodation for incurable cancer patients.

For the presentation of the communications, six different sections had been created, and by skilful organization it had been arranged that papers relating to allied subjects were read in one section, and so far as possible at the same meeting. One of the most interesting meetings was a discussion on carcinogenesis, in which Profs. Kennaway and Cook spoke on chemical compounds as carcinogenic agents, and Dr. Gye on tumours transmissible with viruses. At a subsequent meeting, Prof. F. Pentimalli (Florence) submitted a report on the nature of the agent present in two filtrable fowl tumours. The hereditary factors in cancer were discussed by Dr. Clara Lynch (New York), Prof. Maud Slye (Chicago), Dr. L. Kreyberg (Oslo), Prof. Nadine Dobrovolskaia-Zavadskaia (Paris), Prof. R. Korteweg (Amsterdam), Dr. Wilhelmina Dunning (New York), and Prof. A. Hintze (Berlin).

Communications on the experimental investigation of cancer were submitted by Dr. P. R. Peacock (Glasgow), Prof. R. D. Passey (Leeds), Prof. J. McIntosh (London), Dr. O. Schürch (Winterthur), Prof. Oberndorfer (Istanboul), Dr. I. Berenblum (Leeds), and others. The interesting new subject of transplantable fibro-adenomata of rats and their transformation into sarcomata was discussed by Dr. Ch. Oberling (Paris), and Dr. J. Heiman (New York). Mr. Sampson Handley (London) presented his thesis on the etological importance of lymph stasis.

On the subject of the diagnosis of cancer, Dr. J. Ewing (New York) read a report on problems in histological diagnosis, whilst Prof. L. Hirszfeld (Warsaw), Prof. P. Rondoni (Milan) and Prof. P. Del Rio Hortega (who had specially travelled from Madrid to attend the Congress), discussed the serological and sero-cytological diagnosis of cancer. Dr. Dorothy Russell showed her instructive film demonstrating the tissue culture of gliomata.

The papers read in the section of radiotherapy by Prof. F. Carter Wood (New York), Prof. H. R. Schniz (Zurich), and Dr. L. Mallet (Paris) gave an indication of the progress made in this important branch of cancer therapy as a result of a better understanding of the mode of action of X-rays and radium. By a modification of the previous technique, Schinz has succeeded in obtaining in tumours of the mesopharynx, in which previously radiotherapy had been a failure, a remarkably high percentage of five-year-cures. Schinz also emphasized the importance of radiotherapy as a palliative measure in cancer. This aspect was dealt with in greater detail in the communication of Dr. Mallet. He has applied systematically tele-X-ray therapy to patients in advanced stages of cancer, by exposing large parts of the body at long distances. He showed by numerous illustrations that his method enables him to check the progress of the disease in advanced stages of cancer of the uterus and of the œsophagus, and also in metastases in bones and lungs. Mr. Stanford Cade gave an account of the results obtained by the Curie therapy in pharyngeal cancer.

In the Social Section, the importance of statistics as a scientific method for the investigation of the etiological factors of cancer in man was emphasized in reports by Dr. L. I. Dublin (New York), Dr. W. Cramer (London), and Dr. S. Peller (Jerusalem). Some of the American and German delegates, believing that a morbidity statistic would advance our knowledge, submitted a resolution that the compulsory notification of cancer is advisable from this point of view, and that the Union Internationale should appoint a committee to consider this question.

The incidence of cancer in different races was discussed by Prof. C. Bonne (Batavia), and M. J. A. des Ligneris (South Africa).

The thorny problem of the medical treatment of cancer was discussed in numerous communications. One of these methods which, described as a polyvalent hormonetherapy, had received a good deal of notice in the Continental press, was submitted to a devastating criticism; while the more serious attempts by Prof. E. Freund and Dr. Kaminer of Vienna, which were frankly admitted to be mainly of a palliative nature, were listened to with respectful scepticism.

The general feeling among the delegates was that definite progress has been made both in our understanding of the disease and in the methods of treatment; and that a continuation of this progress is assured. This feeling found expression in the conclusion submitted at the final meeting, in which it was stated, for the first time officially, that cancer is a disease which is not only curable, but also, within limits, preventable.

National Smoke Abatement Exhibition

DURING October, an exhibition and conference is being held under the auspices of the National Smoke Abatement Society in the Science Museum, South Kensington. The interesting Handbook (Pp. 78. Price 6*d*.) published by the Society, the offices of which are at 36 King Street, Manchester, contains twelve articles on various aspects, which are reinforced by another dozen addresses at the Conference held at the Science Museum on October 14–17. Dr. des Voeux, reviewing the smoke abatement movement, mentioned that an exhibition of appliances was held in 1885. Actually one was held still earlier, in November 1881, under most influential auspices and also in South Kensington (NATURE, 25, 219; 1882). The writer has been informed that the organizers were prosecuted for causing a smoke nuisance. Many would be interested to learn that a grate designed by Sir W. Siemens for burning coke and fitted with a gas burner for ignition was a prominent exhibit (NATURE, 23, 25; 1881). The promoters of the 1881 exhibition would have been surprised to learn that a problem which they understood would still await solution after half a century.

Technically, of course, a solution is possible, but the obstacle is a lack of will. Generally speaking, enthusiasts for smoke abatement lack power and influence commensurate with their knowledge and vision. They control neither politics nor finance. As a result it is rare, even now, to find in local government any party making atmospheric cleanliness a primary object of policy. Alteration may, however, come soon. It may be realized by property owners that upper floors of buildings in central urban areas might serve as attractive residential quarters if the air were freed from smoke. That realization might create an interest in smoke abatement in people now indifferent though suffering from the depreciation in value of urban property due to a flight to the suburbs. In one of the papers read, Mr. Noel Carrington blamed the decay of civic spirit in large cities for the lukewarm interest in the smoke nuisance. Those who do not live near their work are prone to be indifferent about the conditions there.

The present activity in rebuilding cities offers an unprecedented chance of replacing smoky by clean fuel appliances, but generally speaking the opportunity is neglected. The opportunity is recognized by public health officials—as shown in Dr. A. S. M. Macgregor's paper on the work of his department in Glasgow; but public opinion rarely gives adequate backing.

The development of flying has brought support to the movement from a new quarter. Flight-Lieut. H. M. Schofield's paper described with terse emphasis how aviation is hindered in Great Britain by atmospheric conditions.

There is no doubt that improvement has taken place in the matter of industrial smoke, but the advance is uneven. In many light industries, the spread in the use of gas and electricity has removed the need for boiler plants, and new factories are often smokeless. However, as H. G. Clinch described, there is often great difficulty in enforcing a high standard, and this is increased by the reluctance of employers to encourage and reward technical training among working stokers.

The heavy industries offer another problem, for generally they are protected by law from prosecution for unavoidable smoke. This exemption has generally deprived them of a strong incentive to seek to avoid smoke. As Mr. H. C. Armstrong said in his paper, Sheffield opinion held that their "steels could not be made without smoke". This was due to the recognized need for maintaining a reducing atmosphere in furnaces. That this could only be done by keeping smoking coal fires seemed so axiomatic as to need no investigation. Recent studies have largely destroyed the basis for this opinion, and new practices are developing in Sheffield and Rotherham, assisted by the development of the 'grid' conveying gas from the coke ovens to the steel works. Mr. Armstrong shows clearly that large technical and financial difficulties retard the rapid abolition of coal-fired furnaces, and that much depends on the availability of cheap gas. A definite amelioration can be looked for.

The same point follows from the examination of the problem of smoke in the clay industries by E. Rowden and A. T. Green. It must have puzzled many to understand why the makers of artistic ceramic ware should be content to live in the atmosphere of the Potteries. The firing of clayware is, however, beset with peculiar technical problems which often demand the use of intermittent kilns. When these are fired by coal, smoke production is inevitable, but efforts are being made to diminish this. Headway is being made with the use of town gas-fired kilns when possible, but cost of fuel is a limiting factor.

These industrial examples show the need for making gaseous fuel cheap if industrial smoke is to be reduced. At the moment, the case of the South Metropolitan Gas Co. has brought forward prominently the question of gas charges, and those interested in smoke abatement will welcome tariffs framed to encourage the displacement of raw coal, not only in the home, but also in industry.

Dr. M. Fishenden reviewed the problem of domestic fuel problems in an illuminating manner, and concluded that although any rapid cure is impossible, present trends to the use of gas, coke, electricity, anthracite should in time be effective.

Three papers dealt with the medical aspects of smoke abatement, two of them with tuberculosis. To-day when the improvement of physique is increasingly regarded as of national concern, it is time to expect that the State will act as though the reduction of atmospheric pollution were something of national importance. A paper by Sir Arthur Hill and Dr. C. R. Metcalfe, on the effect of such pollution upon plants at the Royal Botanic Gardens, Kew, illustrated the direct interest of a public department in the subject.

Only a few of the papers have been mentioned, but all merit study, and together form a very comprehensive survey of the problem as it stands to-day.

H. J. HODSMAN.

Pedology (Soil Science) at the British Association

THE assignment of pedology (or soil science as it is still, unfortunately, termed) to Section M (Agriculture) of the British Association is the natural outcome of its historical development from a branch of agricultural chemistry. But although, in its applied aspect, it has the closest and most vital connexion with agriculture, it is to be feared that it is not entirely at home in the agricultural section. Indeed, if the geologists could be persuaded to adopt it, pedology might more fittingly find a home in Section C. It is probably the exception rather than the rule for papers or discussions to be interesting, or even intelligible, to all attending members, even in the senior sections of the British Association. Section M, however, is expected to be more popular in its appeal, and it might be better in future years to introduce pedology in the form of joint meetings with other sections. Problems of applied pedology might still be assigned to Section M.

One session in Section M on September 14 at Blackpool was devoted to pedology. The president, Prof. J. Hendrick, devoted his address to a review of the development of soil studies in the twentieth century. He directed attention to the great change which has taken place in our outlook on soil science since the beginning of the century. At that time there were no British text-books on the subject, little was known of work in other countries, and the soil was regarded simply as a medium for the growth of crops. Since that time, our outlook has been widened both by the recognition of the soil as an object of study in itself and also by the extension of our interest to include not only British soils but also those of other lands. The study of soils is essentially international, and Prof. Hendrick traced the development of that active organization, the International Society of Soil Science, which held its third Congress in England last year. In the remainder of the address, the newer conceptions in pedology were briefly adumbrated. In conclusion, Prof. Hendrick dwelt on the applied aspect of the subject and its impact on society. Increased knowledge means the possibility of increased production and even over-production, problems for the economist and the social reformer. Yet, whilst malnutrition and under-nutrition exist, even in a prosperous country like Great Britain, the fear of over-production is not likely to restrain the soil investigator from pursuing that fundamental knowledge from which progress in practice ensues.

The remainder of the session was devoted to three different aspects of pedology. Prof. G. W. Robinson dealt with the problems and difficulties of soil classification. Pedology as an independent branch of inquiry being still comparatively youthful, the principles of soil classification have not yet been so clearly defined as in the older disciplines. Whilst there is general agreement in regarding the soil profile as the unit of study, it is not always easy to define its lower limit. Further, actual profiles are not always developed to climax. Apart from complications due to immaturity of development, human interference introduces a group of soil-forming factors which must be accorded their place in a scheme of classification. The importance of giving relevant and precise information about soil profiles was stressed. Much of the published descriptive material is almost valueless through irrelevance and lack of precision. Whilst the final elaboration of a world system of classification must await the accumulation of more information, it seems possible to distinguish three main groups, depending on the character of the leaching processes, namely, (1) completely leached soils; (2) incompletely leached soils; and (3) soils with impeded leaching.

The effect of human interference as a pedogenic factor was raised in the discussion, and it was agreed that the study of soil history is of great importance for the comprehension of contemporary soils.

Dr. R. K. Schofield dealt with the behaviour of soil moisture in the field. Given the importance of soil moisture for the growth of plants, and remembering that the interstitial space of soils is the reservoir not only of water but also of air, the importance of studying the moisture conditions of the soil in profile is evident. Ideally, it would be desirable to follow the moisture changes and movements in each horizon throughout the year. By frequent sampling, a certain amount of information may be obtained, and Dr. Schofield gave the results of observations on the classical Broadbalk field at Rothamsted, on a soil in Utah, and on a soil in the Sudan—the last two under the influence of irrigation.

One of the most striking advances in our knowledge of soil moisture has been the virtual abandonment of the 'capillary-tube hypothesis' and the recognition of the limited role of capillary action in determining water movements in soils. This was stressed in the ensuing discussion by Dr. B. A. Keen, who gave a striking instance of the way in which erroneous ideas of the influence of a deep water-table on surface moisture conditions can still enter into questions of compensation in public schemes for water supply.

Dr. A. B. Stewart dealt with a group of problems in applied pedology by describing the methods used in the advisory service at the Macaulay Institute, Aberdeen. The problems are attacked by three methods, namely, (*a*) field experiments, (*b*) pot experiments, and (*c*) laboratory examination. Since the last method is the cheapest and most convenient, a considerable amount of work has been devoted to correlating laboratory results with field and pot trials. The work is concerned chiefly with the investigation of deficiencies in lime, phosphate and potash. Field and pot experiments are generally in good agreement in the case of potash. In the case of phosphate, agreement is less satisfactory, and the necessity for taking the subsoil conditions into account is suggested. Laboratory methods are, to a large extent, arbitrary and empirical, but, with adequate interpretation, can serve as useful guides to the application of manures and fertilizers.

Soil problems were also dealt with in the session of the Forestry Sub-Section on September 10, where, arising out of an interesting series of papers on afforestation, an animated discussion took place on the possible disadvantages of purely coniferous planting. There was also a discussion on the position of British soils in a world system at a meeting of the British section of the International Society of Soil Science, held in connexion with the Blackpool meeting. G. W. R.

Work of the Government Laboratory

PRESENTING his first report as Government Chemist, Dr. J. J. Fox* refers to the considerable increase in volume and complexity of the work carried out in the Government Laboratory under the direction of his predecessor, Sir Robert Robertson, who held office from March 1921 until April 1936. During this period, the number of samples examined annually rose from about 300,000 to nearly 550,000, whilst the literature of chemistry has been enriched by many accounts of investigations arising out of fiscal and technical developments.

The subject matter of the report follows familiar lines, and provides ample material for satisfaction that the hand of the Government Chemist is on the pulse of so many activities affecting the health and revenues of the nation. Thus one paragraph commences with the words, "In order to ensure that no tea but that which is fit for human food shall pass into the country for human consumption . . .", and records the fact that of the 22,741 samples of imported tea examined during the year ended March 31, 1936, 100 samples, representing 311 packages, were found to contain foreign substances or to be unfit for human consumption. The increase in the number of samples was due principally to the necessity for re-examining nearly 10,000 samples after outbreaks of fire in the warehouses. It is of interest to note that damaged or condemned tea may be used, free of duty, for the manufacture of caffeine, after being suitably denatured with nauseous materials.

Tobacco smokers are informed that in order to maintain the moisture in tobacco and to improve its quality, glycerol or diethylene glycol is added by foreign manufacturers, but such additions are illegal in Great Britain, and the prohibition automatically extends to imported manufactured tobacco. Offal tobacco is used for manufacturing nicotine; now, however, an alkaloid, anabasine, from *Anabasis aphylla*, a weed growing in eastern Europe and northern Africa, is produced for use as a substitute for nicotine in insecticidal preparations. This fact has necessitated researches into methods for the detection of anabasine, and for distinguishing it from nicotine.

Beer is of interest in the Government Laboratory principally in its relation to the revenue, but we are informed in the report that of the 2,115 samples of beer and brewing materials examined, 23 were found to contain arsenic in slight excess of the limit recommended by the Royal Commission on Arsenical Poisoning, namely, the equivalent of one hundredth of a gram of arsenious oxide per pound in solid materials or per gallon in liquids.

Services are rendered to numerous Government departments and offices. Thus the Prison Commission for Scotland desired an opinion on soap; the Post Office on gum, gold thread and ink, among other things; the Mines Department on bath water; the Ministry of Labour on refuse dumps; the Home Office on seized drugs and on matters affecting the health of factory workers; the Ministry of Pensions on Stores supplied to hospitals; and the Board of Inland Revenue on stamps and documents.

Once again we reproduce comments on the composition of cheese and cream. In the paragraph on cheese we read: "The water ranged from 27·0 to 66·8 per cent; the proportion of fat varied from 7·9 to 40·4 per cent of the cheese. . . . As, however, there are no regulations relating to the marking of skimmed or partially skimmed cheese, no exception could be taken to any of the importations". Of tinned cream it is said: "The percentage of fat varied greatly. Two samples contained 50–52 per cent of fat, and the remainder [88] contained from 19–30 per cent. Since there is no standard for cream in this country, exception could not be taken to the samples in respect of low proportion of fat, even when the tins were labelled 'thick cream'". We remind ourselves, with Little Buttercup, that things are seldom what they seem, but we do not find the thought entirely satisfactory.

---

Progress of the Post Office

IN an address delivered to the meeting of the Portsmouth Brotherhood at Portsmouth on October 18, Mr. J. H. Brebner, the controller of press information for the General Post Office, gave a brief account of the history of the Post Office. He laid stress on the fact that in the early days, about 1800, the Post Office was considered more as an instrument for taxation than as an undertaking to be run for the benefit of the public.

In 1801 the Post Office was called on to make a contribution of £150,000 to the Exchequer. The Secretary of that date thought that this was an excellent opportunity to remedy what he considered a grave defect in its system of charging, namely, that the postage was the same whatever distance the letter was delivered, while obviously the charge should vary with the distance. He therefore fixed new rates proportional to the distance the letter travelled. In 1812, for example, the postage from London to Portsmouth was 8*d*. and from London to Thurso 5*s*. A consequence of these high rates was that the illegal conveyance of letters became general. To stop this, prosecutions were undertaken whenever evidence became available. Sometimes hundreds of prosecutions were proceeding simultaneously, and in one case in Scotland there were twelve hundred.

It is instructive to learn that owing to the increased long-distance telephone traffic, an extensive programme of underground cables costing £4,500,000 will be carried out this year. The traffic has increased so rapidly that to enable additional circuits to be provided in advance of the completion of the new cables, schemes are in hand for doubling the capacity of many of the existing four-wire trunk circuits by dividing them into two-wire circuits. Telephone lines more than 100 miles in length will be provided by means of a twelve-channel carrier system, from which twelve telephone circuits will be obtained. This compares with one circuit by normal methods. In this new system, at repeater stations, at every twenty miles, the power of the speech currents can be amplified 100,000 times. The first twelve-channel system will be brought into use between Bristol and Plymouth about the end of this year.

Those who think that radio communication has displaced submarine cables will be surprised to learn that arrangements have been made for the laying of two submarine cables of a new type between Great Britain and Holland, and for one new cable to Ireland. The two Anglo-Dutch cables will provide eleven circuits and the Anglo-Irish cable will provide eight circuits. It is anticipated that further circuits to meet the ever-increasing traffic will be obtained by the installation of additional terminal equipment at a later date.

In conclusion, Mr. Brebner said that the Post Office, by pursuing a policy of reducing the charges for its various services, has grown to be the largest employer of labour in the country. Its ever-increasing profits approximate thirteen millions annually; telephone calls last year were 1,800 million, showing an increase of 140 million over the preceding year. The remarkable progress of recent years is due to the recognition of the fact that the Post Office should work for the common weal. The results which have been achieved fully justify this policy.

Educational Topics and Events

CAMBRIDGE.—D. H. Valentine, of St. John's College, has been appointed curator of the Botanical Museum and Herbarium.

The degree of M.A. has been conferred on Dr. D. J. Bell, University lecturer in biochemistry.

At Trinity College, the following have been elected into fellowships: Dr. N. Feather, on appointment as assistant lecturer in natural sciences, M. H. L. Pryce, for research in mathematics, A. L. Hodgkin, for research in physiology, and T. T. Paterson, for research in geology.

GLASGOW.—Dr. J. W. McNee, University College, London, has been appointed regius professor of the practice of medicine.

The Rector, Sir Ian Colquhoun, is delivering his rectorial address in St. Andrew's Hall, Glasgow, on October 23, at 11 a.m., and a luncheon in his honour is being held in the Bute Hall of the University.

Prof. J. Graham Kerr, M.P., has presented to the Zoological Department of the University a very valuable collection comprising all his zoological manuscripts and the material on which the work was based, including a unique series of *Lepidosiren* and *Spirula*, Budgett's collections of *Protopterus*, and Minchin's slides and material illustrating his study of sponges. Many other collections of great historical interest are included, and will form a basis for many future investigations. In addition, the gift comprises a collection of more than seven thousand books and pamphlets together with various scientific apparatus, and a unique series of demonstration slides which had been accumulated during his long tenure of the chair at Glasgow. In accordance with Prof. Graham Kerr's wishes, the further study of the research material included in this gift is to be restricted to fully qualified investigators, and their work must be carried out in the Department of Zoology at the University.

Prof. F. O. Bower has presented a valuable Zeiss microscope, together with a very complete series of objectives, for the use of research students in the Department of Botany.

Mr. Lewis H. Littlejohn, of the Botany Department, has been awarded a Colonial agricultural research scholarship, and is spending one year at Cambridge and the second year in Trinidad.

NURSERY education problems were dealt with in two papers read before Section L of the British Association on September 11: one by Miss I. Jones on "Nursery Education in Lancashire" and one by Mrs. M. Wintringham on "Emergency Open-air Nurseries in the Distressed Areas". Both papers comment on the favourable influence nursery schools are capable of exerting not only on the children in them but also on the homes from which they come. Miss Jones described two successfully working examples of nursery education: one in "The Tannery School" comprising a full range of classes with children of ages 3–14 years, where older girls are serviceable in the nursery class, finding thus an outlet for mothering instincts, older boys cultivate and keep in order a school garden, and part of the playing field is available for use by toddlers; the other in "The Titan Works School", having only children up to the age of eleven; here conditions point to development into a 'home school' in which parents intimately co-operate with teachers in meeting the needs of the few nursery children. Mrs. Wintringham said of children who have been cared for in the open-air nurseries in distressed areas that "in all cases the teachers of the infant schools, where the children go afterwards, notice how much more alert they are, more independent and adventurous—willing to try" than the other infants. On the question of the effect on family life of "taking the children away from their mothers", she says there are many instances of little reforms and improvements in the personal habits and domestic life of the parents due to the nursery school training.

MR. E. I. LEWIS has issued a pamphlet, "Preparation for Business Careers" (W. Heffer and Sons, Cambridge. 1*s*. net), advocating a course of teaching during the last year of school life which should be a bridge between school and business. Mr. Lewis's ideas were originally presented in an address to a conference of public school masters. He appears to have in mind mainly boys receiving education of a public school or similar type. He does not attempt to deal, "for our present purposes with students in technical schools, colleges or universities. . . ." Mr. Lewis's suggested course aims at avoiding sectional-mindedness and at producing a view of business as a whole, its several parts working to one end. He realizes the present hampering quality of examinations, and sees that only by a new educational treatment can over-specialization be avoided. He makes points which are not new but are in constant need of emphasis. Classical masters, for example, extol the artistic conception of ancient peoples, but neglect their workmanship and their organizing genius. "Whoever would appraise Egyptian, Greek or Roman engineers might with profit consult their living successors". The treatment of subjects, chemistry for example, in vast detail at too early a stage imposes uneven development and imperils chances of promotion to administrative posts where scientific training is needed. No chemist should be content with an education based solely upon the branches of knowledge which directly meet his professional needs; he should enjoy a liberal education, from which flows broad interests, corrective of the narrowness that threatens men who follow professions shut off from the everyday affairs of their kind. With all of which no one who desires to see the scientific worker accorded his proper sphere in the administration of a scientific and industrial world will disagree. Mr. Lewis gives an outline of the subjects of the proposed "Bridge Course", which is the more stimulating since they will by no means find universal agreement.

Science News a Century Ago

Population of England and Wales

The Times of October 26, 1836, contained an article by T. R. Edmonds, author of "Life Tables", on the "Density of the English Population". "The rapid increase of the English population", he said, "during the last 30 or 40 years is one of the most decisive manifestations of our national prosperity. Whilst other European nations are increasing their food and population at the rate of 8 per cent. every ten years, the population of England is increasing at the rate of 16 per cent. every 10 years. The density of the English population is now much greater than that of any other European nation, with the exception of the Netherlands, which being the commercial depot of Germany, is not a fair comparison. In the different counties of England the variations in the density of the population are very considerable; in the manufacturing counties the density is nearly twice as great as in the agricultural counties. . . . In the year 1821, the mean density of the population of England and Wales was represented by 207 inhabitants to each square mile; in 1831 there were 240 to each square mile; and in 1841 there will be 278 inhabitants to each square mile. . . . The comparative densities of the population in the different counties of England is a subject of some importance to the nation and to capitalists. A given extent of territory may, with few exceptions, be presumed to be wealthy or productive in proportion to the density of the population." The article was accompanied by a table of the counties showing the area and the number of inhabitants per square mile; the latter ranging from 4,817 in Middlesex to 72 in Westmoreland.

Death of William Lax, F.R.S.

ON October 29, 1836, the death took place of the Rev. William Lax, the third Lowndean professor of astronomy at Cambridge. Born in 1761, Lax graduated in 1785 from Trinity College, Cambridge, as senior wrangler; he was a Smith's prizeman, and was afterwards elected a fellow of his college. In 1795, at the age of thirty-four years, he was chosen to succeed Dr. John Smith in the Lowndean chair of astronomy and geometry, and after several years spent in tuition was presented to the livings of Marsworth, Buckinghamshire, and St. Ippolyts in Hertfordshire. At the latter place he erected a small observatory, and it was there he died at the age of seventy-five years. Lax was elected a fellow of the Royal Society in 1796, and in 1799 and 1808 respectively he contributed memoirs to the Society on "A Method of Finding the Latitude of a place by means of the Altitude of the Sun", and "On a Method of examining the Divisions of Astronomical Instruments". His "Tables to be used with the Nautical Almanac" was published by the Board of Longitude in 1821. In Lax's time, the University of Cambridge possessed no observatory, and it was due to his successor, George Peacock (1791–1858), Dean of Ely, that one was erected.

The Brussels and Antwerp Railway

THE first railways to be planned in Belgium were those between Ostend and Liège and Antwerp and Valenciennes, and portions of these were opened in 1836. Referring to the railway line between Antwerp and Brussels, the *Athenæum* of October 29, 1836, said: "We learn from *Le Voleur* that this undertaking, which has been in operation only a few months, has already met with great success. The following is an account of the number of passengers who availed themselves of it in the first four months. In May 101,000; in June 98,000; in July 112,000; in August 117,000; total 428,000. . . . This result is extraordinary. The number exceeds that of the travellers by the Manchester and Liverpool Railway, which is upon the average only 80 per train whilst upon the above it is 200. The average price is 1 fr. per person, and the receipts for the four months in question are more than 430,000 frs., which gives an interest of 5 per cent. on the capital."

Societies and Academies

Paris

Academy of Sciences, September 28 (*C.R.*, 203, 573–592).

Edouard Chatton and Mlle. Berthe Biecheler: New evidence relating to the Coccidinia (parasitic Dinoflagellates). The sexuality of *Coccidinium Mesnili*.

Alberto Gonsàlez Domìnguez : A theorem of M. Glivenko.

Paul Montel : Univalence or local multivalence.

Marcel Servigne : The luminescence of solid substances produced by direct excitation in a Geissler tube. Under the experimental conditions described, the light phenomena observed could not have been caused by the action of gaseous ions ; they were due to ultra-violet rays.

René Dubrisay and Albert Saint-Maxen : Researches on the basic lead acetates.

Louis André Germann : Contribution to the study of the mechanism of the condensation between acetone and formaldehyde.

Henri Labbé and Frédéric Heim de Balsac : The presence of vitamin E in the embryo of cacao.

Cracow

Polish Academy of Science and Letters, July 6.

M. Centnerszwer and J. Szper : The electrolysis of some salts in anhydrous glycerol. With copper electrodes, the chlorides of copper, zinc and magnesium, electrolysed in glycerol, give cuprous chloride at the anode and glycerates of the metals at the cathode.

J. Suszko and F. Szelag : The steric inversion of the alkaloids, compounds of the type of the optically active carbinols. The total transformation of quinidine into epiquinidine.

K. Dziewonski and W. Dymek : A method of synthesis of compounds, diaryl derivatives of 2,4-diaminoquinoline.

St. Kreutz : Studies on the luminescence of some minerals. Description of the phenomena observed when fluorite, willemite and calcite are illuminated with a quartz lamp under varying temperature conditions.

W. Vorbrodt : An attempt to use concentrated hydrogen peroxide for the determination of the mineral contents of plant and animal materials. A list of materials is given for which the oxidation is sufficiently complete. The method is specially useful for the determination of phosphorus.

B. Skarzynski : The metabolism of the sterols in the egg of the fowl during its development.

J. S. Mikulski : (1) The influence of constant and alternating temperatures on the survival of some stages of development of *Tribolium confusum*. (2) The influence of constant and alternating temperatures on the variations of the rapidity of development in some stages of the embryogeny of *Tribolium confusum*.

H. Szarski : The anatomy and physiology of the digestive tube of worms of the Naïdin family.

Mme. Z. Opoczynska-Sembratowa : The anatomy and innervation of the heart of *Carausius morosus*.

Taxation, Administration and Research in East Africa

IT has sometimes been questioned by purists in British constitutional practice whether it is advisable that the ministers of His Majesty's Government in charge of Departments of State should have personal experience of conditions in the affairs they are called upon to administer. Whichever way opinion may incline, it is patent that Mr. Ormsby-Gore's tenure of office will afford concrete material for judgment. His knowledge of conditions in the British dependencies is greater than that of any previous holder of the office of Colonial Secretary, and has been approached by none since the days of Joseph Chamberlain. Mr. Ormsby-Gore does not propose to allow his knowledge to lie fallow ; and already both in matters which have arisen under his jurisdiction and in those which he has inherited from his predecessor in office, it has enabled him to show a ready appreciation of the necessity for prompt action and a strong forward policy in native affairs in Africa to remedy or to forestall the dangers, to which he is fully alive, arising out of the dislocation threatening the welfare of African peoples in the present rapid development of economic and social circumstances.

Mr. Ormsby-Gore's dispatch to the Governor of Nyasaland dealing with the report of the Committee on emigrant labour from the Protectorate (see NATURE, 137, 921) is remarkable alike for its independence of judgment and its well-balanced assessment of the conflicting forces, which have to be taken into account in devising measures to meet the trend of circumstances threatening the future stability of the country and its peoples. He intimates that he shares to the full the anxiety of the members of the Committee, and that he agrees to the necessity for immediate steps to remedy a state of affairs, which seems to be bringing hardship and misery to many members of the native community. When he suggests, however, that less spectacular measures may serve the purpose of such of the remedial proposals of the Committee as he has been unable to accept in full, his reasons are in plain view. He goes on to point out that expenditure on a scale, which since 1930 has allocated more than £4,200,000 to the development of the Protectorate and to raising the standard of living of the native inhabitants, cannot continue.

The crux of the native situation in Nyasaland is undoubtedly the hut and poll tax. The Governor of the Protectorate, it is true, and as it appears from the dispatch of the Colonial Secretary, does not admit the contention of the Committee that taxation is the primary cause of the excessive emigration ; but Mr. Ormsby-Gore, while recognizing the influence of a higher standard of living, of the spirit of adventure and of the attraction of conditions of employment in neighbouring territories, holds that the hut and poll tax must be regarded as a most important factor in the present situation. It bears heavily, he maintains, on natives in those areas in which the opportunities of obtaining employment or of selling crops for export are scarce. In this more limited sense, there cannot be two opinions but that he is correct. He suggests, therefore, that taxation in such areas should be reduced immediately. At the same time, he expresses himself as not in favour of the drastic methods of control and restriction of movement advocated in the report of the Committee. To some, Mr. Ormsby-Gore may appear to have been over-cautious ; but in initiating changes among African peoples a certain restraint is no unwise policy.

It is interesting to note how closely in principle the suggestions of the Colonial Secretary addressed to the Governor of Nyasaland are in accord with the attitude of Sir Alan Pim when he touches upon native problems in his recent report on the financial position in Kenya*. Sir Alan Pim's previous experience of adverse conditions among the peoples of the Protectorates of South Africa affords assurance that his diagnosis of factors detrimental to the native population of Kenya may be accepted as well grounded. That this, at any rate, is the conclusion at which Mr. Ormsby-Gore has arrived is indicated by the fact that he has intimated to the Governor, Sir Joseph Byrne, that the recommendations of the report are generally acceptable and should be adopted as a whole.

Not only does Sir Alan Pim regard the system of registration and labour control with little favour, but he also holds taxation of the native, as at present constituted, to be one of the principal factors operating to the detriment of social and economic conditions among them. The case for and against the hut and poll tax, which is estimated to produce the sum of £540,000 in the current year, is stated in detail in this report. No more need be said here than that broadly the conclusion is that this form of taxation is a cause of poverty, is difficult to assess, difficult to collect, and a source of injustice.

Hut and poll taxes were imposed originally on the natives of Africa, as is well known and as has been recalled frequently in recent discussion, in great measure to spur the native to greater activity as a producer and to stimulate and ensure a larger and more steady flow of labour into European employment. This object has been attained at a cost of no little disintegration in native social and economic institutions. In accordance with the recommendations of this report, revision in Kenya is now under consideration.

Sir Alan Pim's recommendations for retrenchment in the finances of Kenya, while sufficiently drastic, though in the opinion of some disappointing in result, are sympathetic towards native claims for consideration. In regard to the medical service, for example, to which the native looks in an increasing degree, he points out that since the Great War a complete change in outlook has taken place, and enlargement rather than retrenchment must be anticipated, although he indicates the road to one possible economy in the development of the non-European sub-medical staff. At the same time, in the matter of scientific research he is by no means over-generous; and although he notes with some approval the desire of the Director of Medical Services to form an Institute of Medical Research for East Africa in Kenya, his general position is that what may be regarded as 'long-term' research must be met from outside sources. This will come as something of a setback to those who appreciate the urgency of inquiry on a much greater scale than as yet has seemed possible without official support on such matters as the nutrition, physical development and the mental capacities of the natives of East Africa, to mention one group only of questions needing investigation.

That there is a wide field for scientific research in matters directly affecting the life of both white settlers and natives in Kenya, and that it is largely untouched, has been deplored on many occasions. It is possible that the solution of the difficulties, financial and other, may lie along lines suggested in the report of this Commission. It is there pointed out that local research in agriculture, for example, might be associated with more advanced study in a centre at either the research institute at Amani in Tanganyika or at the centre for higher education at Makerere in Uganda. Such a solution would facilitate a scheme of co-operation as between the several Territories in East Africa, which might be made sufficiently wide to cover the whole field of appropriate research.

The possibilities of a scheme of co-ordinated and co-operative research in East Africa, in which responsibility for the various branches of inquiry would be distributed among the local governments, deserve to be explored further. Such a question may scarcely be considered to fall within the terms of reference of the newly appointed Commission, which is to proceed under the chairmanship of Lord De La Warr to Uganda early next year, for the purpose of inquiring into the constitution and working of the centre for higher education at Makerere and affiliated institutions, as well as to examine and report on their effect on the educational institutions and systems of the Territories affected (*The Times*, Oct. 20). At the same time, it is a matter upon which even a passing expression of opinion from the Commission, or better a suggestion as to a line of inquiry, would be of inestimable value as a stage towards specific action.

---

High Court Procedure and the Cost of Patent Actions

At the recent meeting in Blackpool of the British Association, the president of Section G (Engineering), Prof. W. Cramp, gave an address on "The Engineer and the Nation" in which he referred to the difficulties in the way of an inventor who patents his invention and attempts to create a new industry. As an illustration of these difficulties, Prof. Cramp mentioned a patent action within his own experience which cost £30,000, more than half of which was spent in obtaining a judgment (reversed on appeal) from a judge who, he stated, admitted that "he could hardly understand a word about it". On this state of affairs Prof. Cramp expressed the opinion that "there is no hope for the Patentee in this country under such a clumsy ineffective system ; but to change it will be difficult. It will be necessary to break through the resistance of a thoroughly case-hardened Bar, and engineers know what that means. I believe that this Association is the only body with the necessary prestige and influence to produce the desired effect. I hope that this Section will urge the Council to take steps to bring about a reform that is so long overdue."

Reform of the patent system in Great Britain has been under consideration more than once during recent years, and the net result is that amended Rules of the Supreme Court are at the present moment being put into effect. This position has been reached by two stages. The first stage included the Departmental Committee on the Patents Acts, presided over by Sir Charles Sargant, and a discussion at the centenary meeting of the British Association in London in 1931. After the Departmental Committee had decided that the cost of patent actions was a subject outside its terms of reference, the subject was brought before the British Association at the centenary meeting. At that meeting, papers on "The Development of Invention" were read by nine representative authorities under the chairmanship of Sir James Swinburne, and the related subjects of High Court procedure and the cost of patent actions were carefully considered. There was general agreement that litigation over patents had become so slow and expensive that only the large corporations or companies and wealthy individuals could afford to go to law over patents, and that there was no satisfactory method of obtaining a decision of very numerous disputes arising on patented inventions. Various suggestions for reform were put forward, of which probably the most interesting was one advocating arbitration of the disputes under procedure similar to that adopted under the London Building Acts. The suggestion, briefly, was that the advisers to parties in a patent dispute should call in either a member of the Patent Bar or some other experienced person to act as a third adviser, and that the parties should agree to abide by any award of the three advisers, signed by at least two of them. This suggestion has not apparently been at all widely adopted.

In the second stage, High Court procedure was considered by the Business of Courts Committee, presided over by Lord Hanworth, and recommendations on the subject were made in the Final Report, 1936. The Committee examined suggestions in regard to rearrangements in the constitution of the Court including (*a*) proposals for the delegation of the hearing of minor patent actions to the Comptroller of Patents or some special officer in his department and (*b*) proposals for the appointment of a special High Court judge to deal with patent business ; and reported against each of these proposals. The Committee further expressed the opinion that the machinery for trial with assessors or with court experts was amply available under existing rules, and that there was not sufficient ground for forcing the machinery upon unwilling parties. In relation to this opinion it should be remembered that Section 31 (1) of the Patents and Designs Acts, 1907–1932, enacts that in an action or proceeding for infringement or revocation of a patent, the court may, if it think fit, and shall on the request of all of the parties to the proceedings, call in the aid of an assessor specially qualified, and try the case wholly or partially with his assistance.

The Business of Courts Committee also considered carefully the possibility of a reform of procedure in the High Court as at present constituted and found an almost universal agreement that it would be desirable, before patent actions come into court, that there should be some means adopted of crystallizing the issues, as well of law as of fact. The Committee recommended that the rules should be amended so as to enable the judge, (*a*) to order the parties to embody their scientific evidence in affidavits to be subject to cross-examination and to be exchanged before the hearing in court, and (*b*) to order the parties to exchange statements (to be signed by counsel), setting out all matters of fact and contentions of law (including contentions on the construction of documents), on which they intend to rely at the trial. These recommendations are now being put into practice by the rules of the Supreme Court (No. 3), 1936, some of the rules being operative from July 13 this year and the remainder from October 12.

In commenting on the patent case that cost £30,000 in the English courts, Prof. Cramp stated that "In France, thanks largely to Napoleon's short way with legal privilege the case given above, with an appeal, cost less than one-tenth of the hearing in the English courts. There, to the best of my recollection, the system is as follows. The court sits to determine if there is a case. Having decided in the affirmative three technical experts are appointed, one by each litigant and one by the judge. These three have access to all apparatus, experiments and documents. Each presents an independent report to the judge and on these the issue is decided." It is a fact that, apart from fees paid to some members of the French Bar who are also eminent politicians or senators, the fees of our Patent Bar are higher than those of the French Bar, and it is true that according to the present procedure in France, the evidence of the three experts is not subject to cross-examination in open court. Nevertheless, it would be unwise to infer from Prof. Cramp's statement that opinion in Great Britain is unanimously in favour of adopting the French procedure, and it is significant that, in the Bill at present before the French legislature, provision is made for cross-examination of the experts in open court, and that this system has already been adopted in the United States.

If any inference is to be drawn from this short statement of High Court procedure and the cost of patent actions, it may possibly be that Prof. Cramp's "case-hardened Bar" shows little indication of bending under the stress of the recent changes and not the slightest indication of breaking. The recent changes have established the present position, and it is unlikely that further changes will be adopted until the present position has been tested, unless they are generally acceptable. It is to be hoped, therefore, that, if the Council of the British Association decides to recommend any further change, it will be specified precisely and will be such as to receive the unanimous support of all the parties interested; otherwise it seems highly improbable that the recommendation will "break through the resistance of a thoroughly case-hardened Bar".

Astronomical Telescopes

Lunettes et télescopes:
théorie, conditions d'emploi, description, réglage. Par André Danjon et André Couder. Pp. xvi+715+14 plates. (Paris: Éditions de la *Revue d'Optique théorique et instrumentale*, 1935.) 100 francs.

THE collaboration of MM. Danjon and Couder has resulted in a notable addition to astronomical literature. The volume under review is the best and most complete book on telescopes that has been written, and it will undoubtedly remain for a long time the standard work on the subject. M. Danjon is the director of the Strasbourg Observatory and a practical astronomer with wide experience; M. Couder, one of the astronomers at the Paris Observatory, is a skilled optician, who made the 81-cm. mirror and other optical parts of the reflector at the Forcalquier (Basses-Alpes) station of the Paris Observatory. The excellent photographs that are being obtained with this instrument are a sufficient testimony to the high quality of its optics. The authors were therefore particularly well qualified for their task.

The volume is divided into five parts. The first part deals with the general theory and use of telescopes. The elementary geometrical theory is summarized, and the limitations of this theory caused by the diffraction of light are then considered. This leads naturally to the question of resolving power, which is discussed in relation to the resolving power of the eye in visual observations and to the resolving power of the photographic plate in photographic observations. The observation of point-sources (stars) and of bodies showing a sensible surface (planets, comets, nebulæ, etc.) are separately considered. Of particular value is a chapter on atmospheric agitation, its measurement and its effect on resolving power.

The careful study of the whole of this part is strongly recommended to amateur telescope users. It will remove many misconceptions and will help them to realize the limitations of their observations. One observer, for example, may describe a comet as having a bright tail but no nucleus; another may describe the same comet as having a nucleus but a scarcely perceptible tail. The two observations are not necessarily inconsistent, but are the result of using telescopes with different apertures and different magnifications. A common misconception is that under conditions of poor definition, it is advantageous to reduce the aperture. An image that is more agreeable to the eye is obtained, but the gain is purely illusory. There is no gain in resolving power and the advantage of the full aperture in the moments of better seeing is lost.

The second part contains a good discussion of the principal aberrations of an optical system, illustrated by numerical examples. The nature of the several aberrations is explained in a very clear manner and their order of magnitude is estimated, using only elementary mathematics. The drawings of focal and extra-focal images, affected by various aberrations, will be found useful in examining any particular telescope for the presence of these aberrations.

The third part is concerned with different types of reflecting and refracting telescopes, and with the design of object glasses and eyepieces. The Newtonian and Cassegrain forms of the reflecting telescope are first discussed; their aberrations are estimated and their limitations are emphasized. These may be termed the classical types of reflector. Alternative designs have been proposed, with the view of obtaining a larger field of good definition. The Schwarzschild, Chrétien, Couder and Schmidt types of reflecting telescope are described and discussed.

A general outline is given of the methods used by the optical computer to reduce aberrations by the combination of two lenses of different types of glass, and several of the principal types of objective are described in some detail. A chapter is devoted to the more common types of oculars and their aberrations.

In the fourth part are described various types of mountings and of miscellaneous auxiliary apparatus; methods of testing and adjusting telescopes; the manufacture of optical glass; the processes for silvering mirrors; the flexure of mirrors and the methods of mounting so as to minimize the effects of flexure; and thermal phenomena, causing variations of focal length and of surface figure. The whole of this part is full of practical information for the telescope user. The adjustment of the Newtonian and Cassegrain reflectors is explained. The testing of an objective for relative tilt of the components, for centring and for tilt of the objective as a whole is described in detail; the method of testing the squaring-on of the photographic plate is also described. A full account is given both of the Hartmann test and of the knife-edge test of Foucault. The method of computing the results of the Hartmann test to show the zonal aberrations and the astigmatic defect is illustrated by the actual figures for the Forcalquier mirror. The result of the Hartmann test is often summed up by a numerical figure, called the Hartmann criterion, which is the weighted mean of the angular aberrations, the weight for each zone being proportional to its distance from the axis. The Hartmann criterion depends upon the origin chosen for the longitudinal aberrations; the origin that gives the smallest value to the criterion is chosen, though this is not necessarily reached in the plane of the circle of least zonal aberration. Moreover, the authors point out that the criterion can only have a significance in relation to the theoretical resolving power of the objective, which depends on its diameter, and, further, that two objectives of the same diameter may have errors of different type and distribution, giving the same value of the criterion, although the images produced by one may be better than those given by the other. In short, though the test gives full information about the defects of figure, the criterion in itself is of relatively small importance.

It is of interest to note the authors' specification for a satisfactory objective: (1) The radius of the circle of least aberration must be comparable to that of the theoretical diffraction image and, in the mean, the reduced transverse aberrations must be smaller than unity; (2) the greatest defect of the surface from tautochronism must not exceed a quarter wave-length and for most of the surface it should be appreciably smaller.

The final part gives a historical account of the invention and evolution of the telescope. The invention of the telescope is often attributed to Hans Lipperhey, a spectacle-maker of Middelburg, in the year 1608. The authors assign the invention to Giambattista della Porta, of Murano near Venice, in the year 1580. Their account of the invention is fully documented, and it seems reasonably certain that, even if della Porta was not actually the inventor, Lipperhey ought not to receive the credit.

Every practical astronomer, amateur and professional, should read this book; many portions of it will be found to deserve careful study. I would urge all who can do so to purchase it; for so comprehensive a work, the price (with the present value of the franc) is very moderate. The expenditure will be found to be a good investment.

H. SPENCER JONES.

The Technique of Biography

(1) Edison, his Life, his Work, his Genius
By W. A. Simonds. Pp. 364 + 12 plates. (London: George Allen and Unwin, Ltd., 1935.) 10*s.* 6*d.* net.

(2) Partners in Progress
By Esse V. Hathaway. Pp. vii + 303 + 12 plates. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 15*s.* net.

(3) Outposts of Science:
a Journey to the Workshops of our Leading Men of Science. By B. Jaffe. Pp. xxvi + 547 + 32 plates. (New York: Simon and Schuster, Inc., 1935.) 3.75 dollars.

THE technique of biography has sometimes seemed to change rapidly in a changing world. The god-like and disembodied abstractions of one phase vanished before the painfully concrete and over-bodied victims of the 'de-bunker', now happily retiring from his brief tenure of the stage. But one aim of the biographer has never, in any worthy practice of the art, varied or failed. The merely superficial account of what a man did never was real biography; the mainspring of action, the 'why' rather than the 'what' and the 'how', must always be the centre of interest in any work of value. The three works before us are all mainly biographical in intent, and must be tested principally for depth of penetration. One of them passes the test triumphantly, the other two are, relatively, insignificant and superficial.

(1) Thomas Alva Edison has always been something of a puzzle to the student of science and technology in the industrial revolution. His career belonged to the 'log-cabin to White House' category, yet no account of his life seemed to recognize that his mainspring of action had not been identified. Every schoolboy was thrilled by the story of his violently episodic progress, his staccato and his sostenuto, his plunges from one subject to another, his living of laborious days and nights in the glamour of wizardry at Menlo Park. But why did he do this and thus, was the glamour real or artificial, was it a spontaneous and so to speak accidental growth, or was it as well engineered as the material products round which it grew? Mr. Simonds, in "Edison, his Life, his Work, his Genius", supplies new factual material and re-presents the old, but of the essence of the man, his genius in the real sense, we feel that we have learnt no more. The restless versatility, the dæmonic energy, are as vividly before us as ever, but why did the man do these things? Was he impelled by an altruistic desire to benefit his kind, was he in search of wealth and power for himself, was the need to "bat the other fellow"—a succession of other fellows—"in the eye" an important element in the good he undoubtedly did for humanity at large?

The questions remain unanswered; Mr. Simonds gives us a good record of fact, but despite the promise implied in his preface he never attempts analysis. He gives us reason to suppose that the first hypothesis is sound, he supplies some evidence for the others, but we suspect his own hypothesis to be merely that Edison did it all because he couldn't help it. We lay down the book with the same feeling of disappointment as with every other life of Edison.

(2) Miss Hathaway does no more for Edison in the score of pages she can spare for him in her verbal picture gallery of "Partners in Progress". The sitters are a well-chosen galaxy from the last twenty-five centuries, but if Mr. Simonds gives us his one sitter in plain black and white, Miss Hathaway presents hers in chromo-lithograph. We just don't believe that Hippocrates was as purple as he is painted; he was probably a grim forthright G.P. without time for rhetoric and romanticism, and he would almost certainly have shared our objection to Miss Hathaway's parsimony with predicates; he might have said with us that what he wanted was verb, not sap. As a cataloguer Miss Hathaway shows talent; her grouping of twenty-five biographies is logical if a trifle obvious. But she adds nothing of value to the already familiar; she pads out inordinately, and her style is maddening.

(3) These two authors might have been more welcome had they not arrived in the company of Bernard Jaffe. "Outposts of Science" is as definitely about people as are the other two works, but there is just enough vivid portraiture to make the *dramatis personæ* fully alive, mainly lovable, occasionally laughable, always humanly understandable. The real dramatic material is the spirit of investigation; the characters in this thrilling presentation of the search for truth are nicely subordinated to their work, their achievements, and partial failures. The major themes are, appropriately, the inner compulsion and the rules of the great game of research, a game in which individual motives are scarcely ever single, but in which single-mindedness is the common dominant.

Boswell's Johnson is as much Boswell as Johnson. Every biography is an autobiography. So in reading the five hundred pages from which the author has apparently excluded himself, we learn to hold in high regard the modest investigator of investigators who tells us in a dozen introductory pages how he made this fine book and what he learnt in the making of it. His four years labour was well spent, and he has done a greater and more difficult service than if he had devoted himself to the physical sciences in which he began his career. One feels that even the star at the eyepiece end of the Mount Wilson 60-inch, of which he tells us in these pages, could scarcely fail to be held by his unrolling of a great scenario.

It is perhaps in part an accident that to a physicist this physicist's account of biological research is more enthralling than his account of physical researches, but it is probably not an accident that the book opens with a chapter in which the story of *Drosophila* is told in a manner which makes this chapter on genetics the most fascinating part of a fascinating whole.

There are many good research workers, there are many good teachers, but there are distressingly few interpreters of Mr. Jaffe's calibre to carry on the vitally important task of explaining the aims, the methods, and the essential achievements of science to the intelligent public. We trust that he will continue his admirable work; he will do well indeed if he does as well as in his survey of the "Outposts of Science".

Biochemical Progress

Annual Review of Biochemistry
Edited by James Murray Luck. Vol. 5. Pp. ix+640. (Stanford University P.O., Calif.: Annual Review of Biochemistry, Ltd.; London: H. K. Lewis and Co., Ltd., 1936.) 5 dollars.

IT is true to say that these annual reports are now eagerly awaited. This year they appeared somewhat later, due it would appear largely to their international character, which is more than ever marked. As evidence of the spread of research institutions of the first class all over the geographical world, it is interesting to note reports from Pretoria, Honolulu, Leningrad, as well as from all parts of the United States and the older European centres. There are twenty-six different reports varying in length and in the ease with which they can be read by the general student who is not an expert in the particular field. In some sections the work is largely pioneer and is still to be correlated; in others a particular stage has been completed and a problem largely solved in preparation for the next step forward.

Gradually more light is being thrown on biological oxidations and reductions. For some of these it has long been known that a co-enzyme is an essential unit in a complex system of reaction components. It is now largely established that such compounds are composed of adenine, phosphoric acid and a sugar ribose, the point of attachment of which to the adenine has now been determined.

Ascorbic acid, the vitamin, is the subject of intense study. Three principal methods are now available for its synthesis, and a number of closely related analogues are available for the investigation of the correlation between constitution and physiological activity. There is evidence that ascorbic acid inhibits the action of certain enzymes unless iron is also present. Such enzymes would appear to contain —SS— compounds in their protein complex which have to be made into —SH compounds for the enzyme to become active. Addition of ferrous ions increases the specificity range of papain and enables the enzyme to hydrolyse peptone. A clue is being obtained which points to the existence of active groupings of elements in the enzymes.

Individual reports by the leading experts deal with the sugars, fats and proteins, either from the point of view of their structure or metabolism, and progress with the hormones and vitamins is fully chronicled; there are signs that the former are now becoming the more fashionable subjects of research. The progress made with the investigation of the structure of the œstrogenic compounds is remarkable and is leading to expansion in many directions as, for example, in regard to the factors involved in the secretion of milk for which lactogenic preparations, which appear to contain a chemical unity prolactin, have been made. Methods of assay of these substances are also having to be developed.

In addition to insulin, many of the hormones are now being manufactured on the commercial scale, so quick has been their application.

All the time, the animal and the plant world are being investigated for rare or new substances—

two new nitrogen-containing extractives have been found in the lower vertebrates, namely, a betaine, homarine, in lobster muscle, and a guanidine derivative, asterubin, in star-fish. More attention is being paid to bacteria, and there are reports on metabolism, soil microbiology and the biochemistry of the fungi.

We have refrained from listing the separate reports or their authors, but we would wish to endorse the thanks conveyed to the contributors by the editors in their preface. It is of great value to the worker to have these judicial summaries by experts made available so promptly each year.

Solubility

Solubility of Non-Electrolytes

By Prof. Joel H. Hildebrand. (American Chemical Society Monograph Series, No. 17.) Second edition. Pp. 203. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1936.) 22*s*. 6*d*. net.

It is not often that a reviewer, who has read through the first edition of a book, finds it worth while to do more than glance through a second edition, in order to discover and review the new sections that have been introduced. Prof. Hildebrand's book is an exception, since the reviewer has taken the opportunity to renew his acquaintance with the earlier as well as the later text, and has found this to be a most interesting experience, since the book is full of matter which is not dealt with adequately (and indeed appears to have been largely overlooked) in the ordinary text-books of physical chemistry.

The book has a strict thermodynamic background, which sometimes makes it rather hard for the ordinary chemist to read, and it is not always easy to bear in mind the significance of the symbols which are carried forward from page to page; but for the most part the conclusions are also stated in general terms, so that the significance of the deductions is easily seen and can readily be applied to concrete cases. The author is, however, now inclined to be sceptical of his former deduction (following Dolezalek) that negative deviations from Raoult's law, which lead in extreme cases to the formation of two liquid layers, can be explained by the association of one of the liquids, since the degree of association required is often fantastic, and unsupported by collateral experimental evidence.

One of the first novelties to be introduced is the author's own conception of 'regular solutions', in which the identity of molecular size and molecular attraction of an ideal solution is not required, but in which "thermal agitation is able to overcome any tendency towards molecular orientation, combination or association, and to give the same completely random distribution as exists in ideal solutions". Under this heading, an account is given of Menke's work in Debye's laboratory on the structure of liquids. The forces between polar molecules are discussed on the basis of London's formula for the interaction of dipoles, and those between non-polar molecules on the basis of Lennard-Jones's theory of force-fields. Other novelties include Langmuir's theory of interfacial energies, Bernal and Fowler's investigation of the structure of water, and Butler's work on metallic solutions.

It is remarkable that the new edition actually occupies three pages less than the old one. This result is surely almost without precedent, and is one on which the author deserves to be congratulated heartily.

L'Espèce

Par Prof. L. Cuénot. (Encyclopédie scientifique: Bibliothèque de biologie générale.) Pp. ix+310. (Paris: Gaston Doin et Cie, 1936.) 30 francs.

This book provides a very helpful account of certain aspects of the species problem. Both the meaning of the concept of species, and the process of specification, are well handled, as is the question of isolation. The examples are, throughout, varied and well chosen.

The author wisely gives a preliminary survey of the genetic phenomena relevant to his purpose, together with a satisfactory description of meiosis. Unfortunately, the general treatment is much hampered by omitting the concept of the gene-complex, and a discussion of polymorphism and of the effects of fluctuation in numbers should have been included in a work of this kind. Likewise some reference should have been made to the various problems of relative growth, and the idea should have been developed that the evolution of rare and abundant species is likely to follow different lines.

However, this is quite a stimulating book, and it is provided with a good glossary, bibliography and index.

E. B. F.

Tables annuelles de constantes et données numériques de chimie, physique, biologie et technologie

(Annual Tables of Constants and Numerical Data; Chemical, Physical, Biological and Technological). Données numériques sur l'effet Raman: spectres, intensités, modes de vibration (Numerical Data on the Raman Effect: Spectra, Intensities, Vibration Patterns). Par Dr. M. Magat. Années: 1931 à 1934. Pp. 112. (Paris: Gauthier-Villars; New York: McGraw-Hill Book Co., Inc., 1936.)

THIS is principally a collection of data obtained on the Raman effect between 1931 and 1934. The substances whose spectra are described are grouped according to their chemical constitution, one fifth of the space being devoted to inorganic compounds and four fifths to organic compounds. In making the compilation, Dr. Magat has attempted to assess the relative reliability of the work of different authors where more than one investigation has been made of a particular substance, and, where necessary and possible, has given mean wave-numbers. He has also made an individual contribution of considerable value in making an attempt to correlate intensity data. It is a pity that so little attention is usually paid to accurate measurement of intensities when the original plates of the spectra are obtained. The methods of photographic photometry are not unduly difficult, and in the present case the technique is often simplified by the fact that the spectrum is comprised within a small wave-length range. There is little doubt that much of the work described here will have to be repeated ultimately on this account, when it becomes necessary to compare it with the rapidly developing theory of polyatomic molecules.

There is an appendix on the modes of vibration of polyatomic molecules, and two lists of papers—in addition to those in the text—one on the theory of the Raman effect and the other on some of its applications. The apparent completeness of the data, many of the sources being inaccessible to the ordinary worker, and the excellent way in which they are reproduced, combine to make the book indispensable for anyone interested in this field.

The Making of Modern Turkey, from Byzantium to Angora

By Sir Harry Luke. Pp. viii + 246 + 1 plate. (London: Macmillan and Co., Ltd., 1936.) 10s. 6d. net.

SIR HARRY LUKE's personal acquaintance with Turkey began so long ago as 1904, and at one point or another he has been in touch with the Turk ever since that date. In consequence he speaks with authority and understanding of the ideals and aspirations which inspired the political and social movements of the present century and have transformed Turkey from the titular seat of an international spiritual hegemony, as was claimed, into a nationalist State. His purpose is not to write a history of the Turks, but to analyse the forces and the elements which, partly rooted in Byzantium, partly arising out of the consequences of the conversion of the Turks to Islam, made the country in the end "the Sick Man of Europe", and in the inevitable disintegration of an international society, left nationalism and a dictator as apparently the only way open to reform.

Sir Harry Luke's critical judgment places recent developments in Turkey in their true historical perspective, and his book is indispensable to anyone who seeks to understand the play of race, language and politics in modern Turkish social development.

Handbuch der Vererbungswissenschaft

Herausgegeben von E. Baur und M. Hartmann. Band 3: Genetik und Tierzüchtung. Von C. Kronacher. Pp. vii + 280. (Berlin: Gebrüder Borntraeger, 1934.) 37.50 gold marks.

THIS handbook of animal breeding is a valuable summary of practical results in the improvement of domestic animals, including rabbits and some birds as well as horses, cattle, sheep, pigs and goats. Such questions as twinning in cattle are dealt with and two pairs of identical twins are described. Various interspecific crosses are discussed, as well as the inheritance of numerous abnormalities in all domestic breeds. The considerable amount of knowledge of serology in the different groups is also summarized. Emphasis is laid on the inheritance of qualities of practical value, such as milk yield in cows, wool characters and fertility in sheep. Such a summary should be of much value to all veterinarians and practical breeders. The book ends with a short index and a full bibliography occupying 87 pages.

An Enquiry into Prognosis in the Neuroses

By Dr. T. A. Ross. Pp. vii + 194. (Cambridge: At the University Press, 1936.) 10s. 6d. net.

THIS is an account of the results of treatment at the Cassel Hospital for Functional Nervous Disorders. The account covers twelve hundred patients. About 40 per cent of the patients reported themselves well at the end of three years, 34 per cent at the end of five years. We do not like to think that the nursing staff were meant to be neutral. An understanding nurse can do so much to help a patient; the doctor need not think he is a little tin god who gets all the patient's confidence. Nurses trained on psychological lines can be so understanding. The common-sense attitude adopted towards the much over-rated *placebo*, occupation therapy, is welcome.

Heredity and the Ascent of Man

By Dr. C. C. Hurst. Pp. ix + 138. (Cambridge: At the University Press, 1935.) 3s. 6d. net.

DR. HURST's little volume is less stereotyped and more discursive than the usual elementary book on this subject. His nine chapters begin with "The Mystery of Life" and the gene, ending on the experimental creation of new species, the ascent of man and the future of man and mind. The gene is regarded as the origin of life, and the evolution of man and his civilization are briefly traced. While highly speculative in places, yet Dr. Hurst succeeds in bringing out many of the salient recent facts of genetics.

Chemistry and Food Science

In the opening paper of a symposium on "Chemistry and Food Science" in Section B (Chemistry), held at the Blackpool meeting of the British Association, Dr. Leslie Harris, of the Cambridge Nutritional Laboratory, spoke of a 'food cycle', analogous to the 'nitrogen cycle' of the chemist. To explain what was meant by the food cycle, he said that food in the first place must be collected or gathered; then it may undergo some manufacturing process; next it may be transported (by sea, rail or road); after which it may be preserved or stored in the cold; before at last it is prepared for the table and eaten. To complete the 'food cycle', it has to be remembered that food, or some part of it, is ultimately converted into manure, and so fertilization is brought into the picture—and with fertilization goes food production, the raising of crops and the rearing of farm animals. In each of these stages of the food cycle, the work of the chemist has been of service to the community, and in the discussion each stage was in turn dealt with by an expert. It might be thought that the logical order is to discuss first food manufacture, and then transport and storage and finally nutrition. On the other hand, all these complicated processes are of no avail, if the final product fails to nourish—so that nutrition must be the final criterion, and may be given pride of place.

On the purely chemical side, as Dr. Harris pointed out, a great body of knowledge has been won in the science of food and nutrition. For example, what were formerly mysterious and intangible 'antiscorbutic' or 'antirachitic' properties in foodstuffs have been shown to be due to 'vitamins', still unidentified and given only vague descriptive letters, C, D, etc. Recently, the chemist has been able to reach one of his final goals by determining the structural formulæ of the vitamins (or five of the better known of them, at least), and in more than one instance he has even synthesized them in the laboratory. The consequences of such discoveries have not been insignificant. For example, the pharmacologist or clinician is now able to prescribe an exact dose consisting of a given number of International Units of an accurately standardized synthetic vitamin. But perhaps more important is the fact that the science of nutrition is now placed on a rational, logical basis instead of being an arbitrary, empirical and rule-of-thumb art. We can now speak with certainty and precision about matters which before, since they lacked formal proof, were open to dispute or disbelief.

THE SCIENCE OF NUTRITION

The next point raised was that it is a mistake to consider food and nutritional science too exclusively from the *chemical* angle. Nutrition is a *biological* process, and therefore can only be adequately studied by the combined methods of biochemistry and biophysics, of physiology and pathology, etc. No progress would have been possible for the pure chemist in his effort to solve nutritional problems without the aid of biological technique, such as animal-feeding tests, biological assays, etc. This is the justification for the existence of that highly trained specialist, the nutritionist—who, to be competent, must needs use the methods not only of chemistry and physics but also those of various biological sciences. In addition, we are beginning to realize that nutrition as a social science is inextricably bound up also with agriculture, and no less with economics.

PREVALENCE OF MALNUTRITION

In conclusion, Dr. Harris said that as a main function of the British Association is to examine "the services of science to the community", the present problem is to inquire how far the science of food and nutrition has served the needs of the people and, more important, how much room there still is for improvement. What constitutes an adequate diet, and how far is it attained in practice? For the present purpose it is not necessary to consider the nutritional needs of the human individual from the more technical aspect —that is, the requirement for given *food constituents*, as fats, proteins, vitamins, etc. It is sufficient to point to the common *errors of diet* as met with in Great Britain, for example, inadequacy of such 'protective foods' as milk, fruit and vegetables.

How can the position as it exists in Britain at the present time be summed up? It is true that people are better nourished than they were (few are now unable to obtain sufficient energy or crude protein), but much remains to be done to furnish a sufficient supply of those accessory factors which are essential for health and optimum growth. In the past, it has been difficult to assess at all accurately the prevalence of malnutrition because of the lack of definite standards of reference: average weights and heights for different age groups are available, but these are not the optima to be striven for. But recently progress in biochemical and other methods has provided specific diagnostic tests for partial deficiencies, and these are now being applied to random groups of the population and might with advantage be utilized on a large scale. Recent inquiries from various angles (for example, Sir J. B. Orr's from the economic side, and a number of surveys from the clinical side) are beginning to make it possible to assess fairly accurately the prevalence of specific disorders of malnutrition in Great Britain to-day.

It is no longer disputed that malnutrition (or 'sub-optimum nutrition') is widespread. It is due to some extent to ignorance, but much more to economic causes—there is still 'starvation in the midst of plenty'; such are the official conclusions of authoritative bodies which have been called upon to give their verdict, such as the International Committees recently appointed by the League of Nations, and by the International Labour Office.

Scientific evidence of malnutrition, presumptive or direct, has been obtained along several different lines: (1) economic (that is, insufficiency of money spent on food), (2) dietetic (inadequacy of food eaten), (3) medical (existence of disorders of deficiency), (4) sociological (comparison of the health standards of poorly-fed and better-fed social groups), and (5) experimental (improvement in health observed in controlled tests when the inadequate food is suitably augmented).

THE PREPARATION OF FOOD

The discussion of the scientific aspect of the preparation of food was very appropriately entrusted to Dr. L. H. Lampitt, head of the research department of an important catering firm.

Dr. Lampitt said that there have been at least five factors stimulating scientific investigations of food. These are—fear of food shortage, fear of war, national economic policies, commercial competition, and one general factor—the desire of man to search into the unknown.

"The coining of the word vitamin," claimed Dr. Lampitt, "has made the English stomach-conscious in a new way, and while I personally cannot see that any nation gains much by that neurotic attention to food which is obvious in certain classes in more than one foreign country, yet possibly an intelligent interest in food can be stimulated which will react to the betterment of the health of our people. One sometimes feels that the vitamin cult has perhaps blinded some of its votaries to the need of calories . . . and perhaps the inorganic salts will receive their due recognition in the near future."

Moreover, as Dr. Lampitt emphasized, people are apt to forget that palatability is a first essential in food, and that proper cooking, in its way, may be as important as a knowledge of calories and vitamins and inorganic salts. Mass production of food, in canning and preserving, and in restaurants, has necessitated the application of science by commercial firms to maintain the quality of food and to enable it to be kept for long periods of time. Thus it is comparatively simple for a chef to make a mayonnaise sauce; but its production in hundreds of gallons, so that the product will remain in good condition, no matter how badly treated by the retailer, and afterwards in the home, involves a whole series of problems which the chemist alone can solve. Mass production also introduces another factor, in the form of metallic contamination. None the less, the unfounded scaremongering about the contamination of food from aluminium cooking-vessels is altogether to be deprecated. Bacterial contamination is another matter, and is one of the most difficult and insistent problems in food industry. But thanks to the help of legislation and scientific investigations, the standard of purity of food in Great Britain is higher, Dr. Lampitt claims, than in many other countries which, in contrast with our own, have the most complete bureaucratic control.

FOOD PRESERVATION AND TRANSPORT

Numerous interesting points were briefly touched on in a paper by Dr. Franklin Kidd, head of the Low Temperature Research Station at Cambridge, which was read in his absence by Dr. Thomas Moran. For example, on the practical side, in the work on proteins, two problems have been solved. In the first place, it has been shown how even the toughest meats from old animals can be rendered tender by hanging for the right time at the right temperature. Conditions are now also understood for avoiding that *hardening* which may occur during preservation in a frozen condition. An important result of this discovery has been that summer catches of choice halibut from far northern waters may now be taken to any region of the earth and eaten at any season. With quick freezing and thawing, and holding at extremely low temperature, the herring gluts of to-day can be preserved and 'spread'. In these matters, as Dr. Kidd concluded, we are at the beginning of great changes in the structure and organization of the fish trade in all countries.

An important aspect of modern food science relates to the conditions of food transport, and these were discussed by Mr. T. Herbert, of the L.M.S. Railway Company. As he pointed out, improvements in refrigeration and chilling processes have created entirely new branches of overseas trade. At home, improved containers have been installed on the railways, and more compact and efficient freezing plant has been evolved. As a result the consumer has been able to receive quicker deliveries, fresher food and greater variety. A vivid impression was conveyed to the audience of the different problems which have already been solved by showing them lantern slides illustrating the imposing provision made on board ship and on rail for the transport of such commodities as meat, bananas, etc.

SOCIAL IMPLICATIONS

That topics concerning nutrition and malnutrition are still liable to be controversial issues was apparent with the opening of the general discussion by the president of the Association, Sir Josiah Stamp, who pleaded for scientific definition of the terms used and statistical treatment of conclusions, and emphasized that these questions have social and even political implications. How, he asked, can one define the "amount of money needed for an optimum diet" when a French housewife is able to manage on so much less than her English counterpart, or how is one to define the "amount of money *available* for food" when it depends on how much of it is spent on beer!

FOOD SCIENCE AND AGRICULTURE

Prof. H. G. Denham, who followed, spoke of the benefits which scientific research has rendered to agriculture in New Zealand, and Prof. W. J. Young, of Melbourne, paid a similar tribute on behalf of Australia. In New Zealand the use of superphosphate has enabled the farmer to put a cow on every acre instead of only one cow on three or four acres. As a result of the drop in its price, the consumption of butter has been greatly increased. In the same way, the consumption of milk might be raised with marked effects for good on many sections of the community. Another contribution of the chemist to agriculture and to food science is the discovery that borax cures a disease of Cox's orange apples. Another is that cobalt, not iron, is needed to secure New Zealand sheep against certain common infectious diseases. Both Prof. Denham and Prof. Young united in expressing their obligation to the work of the Low Temperature Research Station at Cambridge.

The value and indispensability of the contribution of the analytical chemist to food science was the theme chosen by Dr. G. Roche Lynch, president of the Society of Public Analysts and other Analytical Chemists. As he pointed out, much of our "newer knowledge of nutrition" has its origin in the work of the public analyst in controlling the adulteration of food.

Positive Economics of the Fungi

THE emphasis of the study of economic mycology is so much upon the negative side, the effect of fungi as producers of disease, that it is very stimulating to have the presidential address to Section K (Botany) of the British Association, delivered on September 10, deal with the beneficial activities of these organisms. Mr. J. Ramsbottom has collected very numerous examples where fungi are of positive value to the community, and his paper makes fascinating reading.

Perhaps the most obvious use of fungi is as articles of food. In addition to the common mushroom, blewits (*Tricholoma personatum*) and species of the genus *Boletus* (*B. edulis* and *B. scaber*) are eaten in Great Britain; but Mr. Ramsbottom also mentioned the use of *Pholiota ægerita* and *Polyporus tuberaster*, of literary lore, the Canadian *Grifolia* (*Polyporus*) *Tuckahoe*, the Indian bread of America (*Poria cocos*), the blackfellow's bread of Australia (*Polyporus mylittæ*) and various tropical species of the genus *Lentinus*. Three species of the larger fungi are cultivated by man, namely, the field mushroom, the shiitake (*Cortinellus Shiitake*) and *Volvaria volvacea*. A historical review of the development of mushroom culture finds a natural place in Mr. Ramsbottom's paper, and a consideration of modern methods of pure-culture also appears therein. Production of the shiitake has little horticultural similarity to mushroom growing. A pile of logs is sprinkled with powdered wood from previously infected material, or covered with straw mats bearing spores. The cultivation of *Volvaria volvacea* is less precise, for heaps of rice straw, chopped banana leaves, or other vegetable refuse, are merely watered with rice-wash or sugar-cane juice, and usually bear within a fortnight. There is an extensive cultivation of this fungus within the tropics.

Truffles (*Tuber* spp.) still occur in Great Britain, and Mr. Ramsbottom's paper contains an implicit invitation for field mycologists to follow the example of C. E. Broome, who, in the middle of last century, always used a rake upon his fungus forays, and found truffles from very numerous localities.

A whimsical reference to the criminal use of poisonous fungi led to a consideration of the medicinal value of certain species. *Lycoperdon Bovista* has been used in the past for stanching wounds, ergot of rye (*Claviceps purpurea*) holds the seal of the British Pharmacopœia, and many other examples of more homely uses of fungal remedies are given. *Cordyceps sinensis*, a parasite of caterpillars, is much used in China, being sold along with the caterpillar, and tied with red silk.

Perhaps few dentists or fly fishermen would recognize the soft flesh of *Fomes fomentarius* as the amadou of their craft, and relatively few photographers have experienced the use of the inky juice of *Coprinus comatus* as a retouching medium. Hottentot and Egyptian ladies used fungus spores as face powder, and one wonders why their modern sisters have not made greater use of the delicate shades of spore colour for this purpose. Wood attacked by fungi is not necessarily worthless. The green colour of oak or birch attacked by *Chlorosplenium æruginosum* is the 'green wood' used in the manufacture of Tunbridge ware, whilst 'brown oak' of commerce is the result of inoculation with *Fistulina hepatica*. A most fascinating use of a mould, *Mucor racemosus*, is described from Chiloe Island and eastern Patagonia, for there the wood of such trees as *Eucryphia cordifolia*, *Weinmannia trichosperma* and species of *Nothofagus*, is converted to a palatable food for cattle by the agency of the fungus and associated bacteria.

No account of the uses of fungi would be complete without some reference to the symbiotic mycorrhiza of orchid plants. The work of Noel Bernard showed that inoculation with a fungus was necessary for the germination of orchid seeds, and gave abundant growth where previously had been great waste of seed. Although the work of B. L. Knudson has shown that the seed can germinate under aseptic conditions, if supplied directly with glucose, the symbiotic method of Bernard is still used extensively in some countries.

A very large part of Mr. Ramsbottom's address dealt, very naturally, with fermentative changes brought about by fungi. As an introduction to this section, he quoted the discovery of nineteen different enzymes—"apparently sufficient for any purpose here below"—from the fungus *Aspergillus Oryzæ*. Compressed yeast, which is now used extensively in bread manufacture, has evolved gradually from the older preparations, as leavens, barms and more liquid ferments. Wines are still made chiefly with naturally occurring yeasts, usually allied to *Saccharomyces ellipsoideus*; but various strains of *S. cerevisiæ* are maintained in pure culture for all the more distinctive brands of beer. A point of general mycological interest is the discovery by K. Kruis and J. Šatava that there is an alternation of generations in yeasts; *Torula* and other non-sporing forms are regarded as haploid phases.

The world's coal resources must come to an end sooner or later, and it is very satisfying to have the assurance that suitable methods for the production of power alcohol could be brought into operation on a large scale, as soon as international interest should demand. Fungal organisms can also be employed for the conversion of starch to sugar in malting operations, and give better results than the use of enzymes derived from the germinating grain.

Mr. Ramsbottom had many interesting facts to relate about the production of fermented foods and drinks. The reader cannot but revel in the international nature of his discourse, for he described the preparation of *shoyu koji*, from soy beans in Japan, China, Java and other countries, *tamari*, *miso*, *to-fu*, from the same parts, *saké*, a beverage made from rice in Japan, and the ripening of various kinds of cheese in all parts of the world, and probably dating back to Neolithic times. There is also detailed mention of Russian *kvass*, Mexican *pulque*, *laette* in Scandinavia, the old English ginger-beer plant, *kephir* and *koumiss*, beverages made from fermented milk in central Asia, *leben*, a similar drink of Egypt, and *mazu* of the Armenians. The accounts of cheese-ripening are particularly interesting, and many practical problems are described. One cannot but sympathize, for example, with the up-to-date farmer who pulled down his old wooden dairy shelves, and replaced them with tile and slate, only to find that he had also parted with the "esteemed special quality" of his Stilton cheeses—the wooden shelves had been the unsuspected culture medium for the specific organism concerned.

The work originated by Pasteur led to a new era in the production of organic compounds, and since the time when Van Tieghem, Pasteur's pupil, first studied the formation of gallic acid from tannin, many compounds have been produced mycologically. Glycerol, which is a very important compound in many industries, can be produced if sugar is fermented in the presence of alkaline salts. W. Connstein and K. Lüdecke, under the stress of war conditions in 1914, showed that disodium sulphite was much more suitable than the commoner alkaline salts; it could be added in large quantities without detriment to the yeast, and kept out other contaminating organisms. Commercial diastase, oxalic and citric acids, gluconic acid, and an imposing host of organic compounds, some of them never previously prepared in the laboratory, have been made by the action of fungi. Exhaustion of our coal reserves need have no terrors, for in addition to power alcohol, dyestuffs can be made with the aid of fungal organisms. α-Hydroxyanthroquinone pigments can be produced through the agency of certain species of the genus *Helminthosporium*. Ergosterol, fats and proteins must also be added to the list of mycologically producible substances, and the discovery by Chapman that a species of *Oidium*, found to be blocking sewer channels, could produce a thick film on nutrient medium, which had the odour and flavour of cream cheese, illustrates the romantic possibilities of science.

There is a great deal in Mr. Ramsbottom's address which can be used to render the acquirement of knowledge by the student a pleasant experience. The subject-matter is about candy, cheese, 'Marmite', coffee, mushrooms, baking and brewing—instances of common experience; but the discourse gave sufficient detail to make it of interest to the technician also. The dominant impression was one of confidence in the future. Natural mineral resources are now being exploited at an enormous rate, to produce power, dyestuffs and various chemicals; but many of these needs could also be met by the gentle ministrations of fungi. Perhaps the large number of substances already produced by these organisms might be taken as earnest that man need not fear the exhaustion of Nature's experiment with carboniferous conservation.

Genetics and Ecology in Relation to Selection

ONE of the most striking features of post-War biology has been the reanimation of Darwinism on a genotypic, instead of a phenotypic, basis. That such an attitude to evolutionary theory derives strong support from modern genetic and ecological work is undoubtedly the chief fact which emerged from the discussion on selection held on September 10 by Section D (Zoology) of the British Association at the recent Blackpool meeting. This occupied the first morning, and immediately followed Dr. J. S. Huxley's presidential address to the Section, which itself provided a comprehensive introduction to the subject. For his review of "Natural Selection and Evolutionary Progress" was a remarkable achievement, including almost everything that could and should be said in a general survey of selection.

In recent years experiment has largely replaced observation in the study of evolution. It is now plain that selection can operate only on genotypically controlled variability. Consequently, the effects of mutation, which is the initiation of a heritable variation, demand careful study. That these are nearly always disadvantageous need, however, cause us no surprise, for any organism must represent a system carefully balanced and adjusted to its environment; so that any random change within it is immensely more likely to impair than to improve its efficiency. Yet occasional mutations have actually been observed which might be of advantage at least in special circumstances: like that mentioned by Dr. Huxley, in which a variety of tobacco failed to flower until the ratio of light to darkness was altered to correspond with what would prevail in a semi-tropical summer, when it proved superior to the normal form. But the relative viability of the genes may be most favourably compared in crowded cultures, when it can be studied as a deviation from expectation in Mendelian ratios. Dr. Timoféef-Ressovsky, who has elaborated this technique, pointed out that such tests also demonstrate that genes have different survival values in different degrees of crowding. For this work he has employed populations of *Drosophila*, and his method has provided an experimental basis for the study of selection in the laboratory.

Using the same genus, Dr. C. Gordon has now supplied proof of selective elimination in Nature. He finds that the number of autosomal recessives is very significantly in excess of the number of recessive sex-linked genes per length of chromatin —a discovery to be correlated with the fact that selection can operate on the former only when the genes in question are present in double dose, but on the latter, in every individual of the heterogametic sex in which they occur. Dr. Gordon has also demonstrated the reality of selection in Nature by releasing, and afterwards studying, a balanced population of *Drosophila melanogaster*. This consisted of normal and 'ebony' flies in a known ratio, set free in England, where the species is not indigenous. The latter is a dark mutant form, mono-factorial and recessive. It proved to be progressively eliminated in the open.

Selection, however, operates not merely to reject one character and conserve another: it may also alter the *effects* of the genes, but not the genes themselves. This view, the evolutionary implications of which have been developed only in recent years, follows naturally from the consideration that genetic factors interact with one another to produce the characters for which they are responsible. Thus mutations which are pathological in one gene-complex may be harmless or even advantageous in another, and such effects are open to the influence of selection. This concept, ably elaborated in Dr. Huxley's address, was illustrated by Mr. E. B. Ford by an example drawn from work on *Gammarus chevreuxi*. A gene which changed the eye-colour from black to red at one mutation, changed it to brownish when it mutated in another stock. A mating between the two showed that the same locus was concerned. Furthermore, successive back-crossings of each type of red into the other stock reversed their effects, demonstrating that the phenotypic difference was due to the action of the total gene-complex, not to mutation to another allelomorph at the same locus.

The effects of the genes, then, are susceptible of modification by selection, and Mr. Ford pointed out that the evolution of polymorphic mimics can be explained by no other means. It is often found that two forms of mimetic butterflies, each highly adapted in a number of distinct characters, are controlled by a single factor-pair. The allelomorphic difference concerned must have originated spontaneously by mutation, but we cannot suppose that selection has had to wait for the fortuitous occurrence of a change producing all the characters required. Such would seem an almost impossible event even in a single instance, yet the condition is common. The alternative explanation of the occurrence of parallel variation in model and mimic is disposed of by the superficiality of the resemblances between them. Thus Mr. Ford has found that the red pigment produced by the mimetic forms of *Papilio polytes* is chemically different from that of the models, though this is well known to be an instance in which the polymorphism concerned is under simple Mendelian control.

Furthermore, the study of mimetic insects has clearly demonstrated the reality of selection as an agent in stabilizing the population. Prof. G. D. Hale Carpenter, who discussed the forms of *Pseudacræa eurytus*, which mimics various species of *Bematistes*, has collected this butterfly on an island in Lake Victoria in which the proportion of models to mimics varied in different years. He found that when the models were the commoner (70 per cent of the association), intermediates between the different forms of *P. eurytus* were rare (4 per cent or less); but when the mimics were in excess, such intermediates were quite frequent (11–30 per cent).

Finally, Darwin's view of sexual selection has evoked much criticism. It is rightly felt that his analysis of this subject is one of the least satisfactory steps in his argument. However, Mr. F. C. Minns provided evidence of sexual selection in budgerigars. He further pointed out that in some forms the process must favour vigour and activity in the male and the reverse in the female, a condition proved in *Drosophila*.

It was the duty of Prof. H. J. Muller to summarize the whole subject, and he performed this difficult task with success. There can be no doubt about the value of a carefully planned discussion such as this, illuminating, as it did, a single problem from widely different angles. Each of the speakers has himself worked on the particular aspect of selection which he developed, and took the opportunity to bring forward recently ascertained or unrecorded facts.

Obituary

Dr. W. H. Harrison

WE regret to record the very sudden death, on August 18, of William Hudson Harrison, late of the Indian Agricultural Service, at his home near Leeds. Harrison was born in 1876. He graduated with honours in chemistry at the Yorkshire College in 1897, having been highly distinguished as a student and personally beloved by all. After graduation he was appointed chemist and manager at Knostrop Sewerage Works, Leeds, which post he held for nine years, receiving the warmest appreciation for his work both from the Leeds authorities and from the Royal Commission on sewage disposal.

In 1906 Harrison was appointed agricultural chemist to the Government of Madras, India. Here he commenced work by carrying out some valuable soil surveys, and then went on to a study of rice cultivation as practised in India under swamp conditions. He discovered the most obscure phenomena, and proceeded to elucidate them step by step. His work was highly original and practical and is assuredly a classic in this field. His papers are a record of his resource and genius. For his earlier papers on this subject he was awarded the D.Sc. degree of the University of Manchester.

Harrison's extensive work on swamp soils can only be referred to here in mere outline. His preliminary observations showed that the anærobic fermentation of soil organic matter and green manure in these submerged soils produced large quantities of methane and nitrogen and relatively small amounts of carbon dioxide and hydrogen. On the other hand, anærobic fermentation of green manure without soil to hold up the gas produced much carbon dioxide and hydrogen in the first phase and carbon dioxide and methane in the second phase. Only a small amount of gaseous nitrogen was formed. Other experiments showed that by a secondary reaction under swamp soil conditions, carbon dioxide and hydrogen are recombined by bacterial agencies with the formation of organic matter and even methane. Hence the important conclusion was reached that the gases actually found in swamp soils are a residue of the gases produced in the primary fermentation, thus providing a rational explanation for the peculiar composition of the soil gas.

The gas evolved from the surface of swamp soils was found to consist mainly of oxygen and nitrogen. This gas is entirely distinct from the gases in the soil, and the soil gases do not normally escape from the surface. The evolution of oxygen at the surface was shown to be the work of a mixed film composed of certain bacteria, diatoms and algæ. The bacteria were isolated and characterized and shown to have the power of oxidizing methane and hydrogen. The photosynthetic utilization of carbon dioxide with liberation of oxygen by the film was proved, and it was shown that the development of oxygen was dependent upon the supply of methane and carbon dioxide from the soil gases.

From these and other inquiries, Harrison demonstrated that an important indirect manurial effect of green manure is to aerate the soil water in this type of cultivation. Comparing cropped and uncropped soil, it was found, among other interesting facts, that cropping greatly increased the formation of gaseous nitrogen, especially during the later stages of growth. Evidence from numerous experiments showed that the extra nitrogen formed in cropped soils is derived from the fermentation of dead roots which accumulate as the plant grows. The nitrogen cycle did not seem favourable, and it is evident that Harrison was aiming at further work on this aspect of the subject, but at this stage he was appointed Imperial agricultural chemist and transferred to Pusa. The appointment was an honour and a call to greater responsibility. He had to abandon his work on rice, but he has left a contribution which is unique.

At Pusa, Harrison undertook inquiries into soil nitrates and phosphates and soil reaction. The work on the influence of calcium carbonate on the penetration of certain phosphatic manures into the soil yielded notable information. Eventually administrative duties filled more and more of his time. He was first appointed joint director of Pusa and later became head of the service as director and agricultural adviser to the Government of India, from which post he retired in 1931.

Dr. Panchanan Mitra

THE death occurred on July 25, after a short illness, of Dr. Panchanan Mitra, head of the Department of Anthropology of the University of Calcutta.

Panchanan Mitra, born in Calcutta on May 25, 1891, was a member of a family already distinguished in the study of Indian history and culture. His grandfather, Raja Rajendra Lal Mitra, was the first Indian president of the Asiatic Society of Bengal. After a distinguished career at the University of Calcutta and four years as a lecturer in English, Panchanan Mitra in 1919 was awarded the Premchand Raichand Scholarship of his university for a thesis afterwards (1923) published under the title "Prehistoric India"; and in the same year was appointed to the staff of the Department of Anthropology, of which he became head on the retirement of Diwan Bahadur Dr. Anantha Krishna Iyer in 1932. In 1929, at the instance of Dr. Craighill Handy, he was appointed to a fellowship of the Bernice P. Bishop Museum, Honolulu, and travelled extensively in Polynesia, collecting evidence bearing upon the problem of the influence of Indian cultural traits on Polynesia. His results are now on the point of publication. A period spent at Yale University working with Dr. Clark Wissler on distributional studies resulted in "A History of American Anthropology" (Calcutta, 1931), for which he was awarded a Ph.D. In 1931 also he visited Spain and southern France as a member of the American School of Archæology in France. Two years later he presided over the Anthropological Section of the Indian Science Congress.

Dr. Mitra was not only himself a distinguished research worker, but he was also an organizer of research. He was responsible for the close conjunction of research in the laboratory and in the field, which is now an important feature in the work of his Department. His premature death is a great loss to anthropological studies in India.

Prof. Eugène Lagrange

EUGÈNE LAGRANGE, seismologist and emeritus professor of physics at the École militaire at Brussels, died in that city on June 15 (*Boll. Ital. Soc. Sism.*, **34**, 156; 1936). Born in 1855, he entered the École militaire in 1873 and, after passing through its course, was appointed first as assistant professor, and then as professor, of physics, an office that he held until his retirement in 1907. In 1898, he spent some time in Strassburg, in order to become acquainted with the use of seismological instruments. Through the generosity of M. Ernest Solvay, he was enabled to construct a seismological station at the Royal Observatory of Uccle, where he installed three horizontal pendulums of the Rebeur-Ehlert type. His observations there were continued until the end of 1903, when M. Solvay presented the station to the Belgian Government. At the same time, two other stations were placed under his direction, one of them at a depth of more than half a mile in a disused passage of a coalmine, the principal object of which was to discover if any relation exists between microseismic movements and the emission of firedamp. From 1908, Prof. Lagrange directed the well-known journal *Ciel et Terre*, until, in 1910, it was combined with the *Bulletin de la Société belge d'Astronomie*.

Mr. Alan A. Blakeway

WE regret to record the death, at the age of thirty-eight years, of Mr. Alan Blakeway, director of the British School of Archæology at Athens, which took place at Winchester after an operation on October 9.

Alan Albert Antisdel Blakeway was a son of the late Charles Edward Blakeway, Archdeacon of Stafford, and was educated at Shrewsbury School and Christ Church, Oxford. After taking first class honours in the school of *Literæ Humaniores*, he was for six years a master at Winchester, and then in 1931 was elected a fellow and tutor in ancient history of Corpus Christi College, Oxford. In May last, on the death of Humfry Payne, he accepted the directorship of the British School for the time being. His death took place on the eve of the opening of the exhibition at the Royal Academy of Arts, which celebrates the fiftieth anniversary of the School, and in the preparations for which both he and Payne had taken a very active part.

Blakeway had excavated on behalf of the School both at Perachora and in Crete, and he had for long been engaged in research on the commercial relations of Greece with Italy, Sicily and France in the eighth and seventh centuries B.C. The first fruits of his researches, which he had begun to publish in the *Annual* of the School and the *Journal of Hellenic Studies*, had already won recognition as of outstanding merit.

WE regret to announce the following deaths:

Dr. J. W. Folsom, senior entomologist in the United States Department of Agriculture, an authority on cotton insects, on September 24, aged sixty-five years.

Dr. George Forbes, F.R.S., formerly professor of natural philosophy in Anderson's College, Glasgow, on October 22, aged eighty-seven years.

Prof. F. Hendrickx, emeritus professor of veterinary medicine in the Belgian Veterinary School.

Dr. S. M. Kintner, vice-president in charge of engineering of the Westinghouse Electric and Manufacturing Company, formerly professor of electrical engineering in the University of Pittsburgh, an authority on radio engineering, on September 28, aged sixty-four years.

Prof. W. A. Parks, F.R.S., professor of geology in the University of Toronto, on October 3.

Dr. E. E. Prince, former Dominion Commissioner of Fisheries, Canada, an authority on the life-histories of marine food fishes, aged seventy-eight years.

Dr. Gustaf Schack-Sommer, a pioneer in the sugar-beet industry in Great Britain, aged eighty-two years.

Prof. G. Sergi, emeritus professor of anthropology in the University of Rome, aged ninety-five years.

Prof. W. J. Sollas, F.R.S., professor of geology in the University of Oxford, on October 20, aged eighty-seven years.

News and Views

Prof. A. R. Radcliffe-Brown

ALFRED REGINALD RADCLIFFE-BROWN, who has been appointed to the recently instituted professorship of social anthropology in the University of Oxford (see p. 772), was educated at the King Edward High School, Birmingham, and Trinity College, Cambridge, where he was elected to the Anthony Wilkin scholarship in ethnology, carrying out ethnographical investigations in the Andaman Islands. He was a fellow of Trinity College from 1908 until 1914, and a lecturer in ethnology in the University of London in 1909–10. After the Great War, Prof. Radcliffe-Brown held an educational post in Tonga for a time and was afterwards on the staff of the Transvaal Museum until he was appointed to the chair of social anthropology in the University of Cape Town in 1921. This he held until his appointment as professor of anthropology in the University of Sydney. Here, as at Cape Town, he was active in promoting ethnographical work in the field, and the present activity of anthropological studies in Australia is largely due to his enthusiasm and power of organization. In 1931 he left Australia to join the staff of the University of Chicago. Prof. Radcliffe-Brown was president of the Anthropological Section of the British Association at the centenary meeting in London in 1931, when he dealt in his presidential address with the methods of investigation in social anthropology, of which he had already given a practical demonstration in "The Andaman Islanders", which is, up to the present, his most important and considerable contribution to anthropological literature.

National Museum of Wales and Welsh Cultural Studies

IMPORTANT developments in policy and organization, made possible by an increased Treasury grant, were announced in the annual report of Council of the National Museum of Wales, which was presented at the court of governors held at Cardiff on October 23, when Mr. W. G. A. Ormsby-Gore, vice-president of Council, was in the chair. An immediate addition of £1,500 per annum, to be followed by two increments of £750 per annum, will raise the Treasury grant to £20,000 per annum in all by April 1, 1938. Of the additional income, the Council proposes to set aside part to form a fund for the purchase of collections of outstanding importance, otherwise beyond the normal resources of the Museum. Of even greater interest, however, is the second development, to which effect has already been given. The Sub-Department of Folk Culture and Industries within the Department of Archæology has been advanced to the status of a full department. It will cover the national ethnography and cultural history of Wales from the Act of Union of 1536 to the present day, with the proviso that the modern industrial civilization will not be covered, save to a limited degree. It will, therefore, concern itself with the trades and crafts, the ways of living and working, the domestic and industrial environment, and the clothes and customs of past generations of all ranks of the Welsh people. The enhanced status of this section of the National Museum is no more than due recognition of the value of a piece of work to which much time and research have been devoted by the responsible authorities, and from which important studies have already accrued. The collections at Cardiff illustrating the life and culture of the Welsh people—even more now that this opportunity for expansion is afforded them—provoke regret that no similar unitary collection deals in like manner with the folk history of England.

Future of Liquid Fuel Production

SIR PHILIP DAWSON's presidential address to the Institute of Fuel on October 15 entitled "Road, Rail and Fuel" emphasized our dependence on imported liquid fuel, and especially motor spirit. He stated that in the present year, Germany will produce more than fifty per cent of her needs of light motor fuel. The use of Diesel fuel is increasing in all forms of transport. Discussing the relation of road and rail, he said that the former employs almost twice as many persons as the railways, and in ten years the number of railway employees has fallen by fourteen per cent. Sir Philip advocated an extension of railway electrification, but pointed out that this would involve a big reduction in the consumption of coal, even were the power generated from steam boilers. At the same meeting Dr. Franz Fischer, of the Kaiser Wilhelm Institut, Mulheim, delivered the Melchett Lecture to the Institute, taking as his subject the conversion of coal into liquid motor fuels and other products by way of carbon monoxide. Having indicated the advantages of beginning with a single pure gas such as carbon monoxide rather than raw coal, as in direct hydrogenation, Dr. Fischer traced the development of his work from 1921 until the present stage when large-scale plant is in use. Very extensive efforts were necessary in the search for a suitable catalyst and a method for adequately purifying the gaseous raw material. Hydrocarbons ranging from petrol to paraffin wax are obtained by this 'Kogasin' synthesis. Thus these researches have shown that from coal and water all necessary liquid fuels would be obtainable from coal even if mineral oils were entirely exhausted. Fischer's process offers the advantage over the process of direct hydrogenation, that high pressures are not used and that only plant of common materials, easy to fabricate, is required.

Electric Services in Buildings

MR. H. T. YOUNG, who is connected with the installation and contracting section of the electrical industry, gave his presidential address before the Institution of Electrical Engineers on October 22. In the early days, electrical installations in buildings were for lighting and bells. Wood casing was used, and, so far as possible, it was concealed from view. Cables, wires and equipment were placed anywhere where they would be out of sight. Now new and larger buildings are being erected all over the country, and electrical contractors are having difficulty in doing their work satisfactorily under the new conditions. The steel and concrete buildings of to-day, if once completed, are almost impregnable to electric services. The item in electrical accounts entitled "cutting away and making good" averages about ten per cent of the cost of the whole installation. In new buildings which are planned and designed for electrical services, this item is much smaller and the time of building is accelerated; Mr. Young urged that channels, ducts and conduits for the reception of wires and cables should be considered in the future as an integral part of the building from the point of intake to the outlets. In the United States and Canada, underfloor duct systems have been adopted for more than ten years as standard practice in nearly every type of building, except private houses. The ducts are made of steel or fibre and are laid in the floor during construction. In Great Britain, a beginning of the duct system has been made. Three ducts are used, one for telephones and signalling wires, one for heating and power, and one for lighting.

MR. YOUNG showed lantern slides of installations in progress and completed where electrical engineers and architects have planned their work together. In particular, he mentioned the new buildings of the University of London, which he said are the most interesting buildings in the course of erection in the country to-day, and also seem to have the most complete electrical installation, as the lighting, space-heating, water-heating, and many other services are all electric. There is one flue only, and that is for a coal fire in an official's study. In blocks of flats in London, arrangements are now being made for the reception of sound and television services. These are taken from one central aerial system and distributed by cables to a terminal box in each flat. The tenant receives both services on his own equipment through a 'socket outlet' and plug attachment. A special type of cable is used for carrying the extremely high frequency currents used in television. The estimated total annual consumption of all-mains radio sets is 300 million units. This equals twice the estimated load in 1910 for lighting, heating and cooking. He mentioned that a large store in London (Selfridge's) has an annual consumption of electricity (7¼ million units) which equals that of places like Weymouth, Perth, or the whole of the Isle of Wight. There are other buildings in London, such as stores and hotels, which consume five million units per annum. He considers that none of these could be described as fully equipped electrically.

The Training of the Engineer

IN his inaugural address as president of the North-East Coast Institution of Engineers and

Shipbuilders on Friday, October 23, Prof. C. J. Hawkes took as his main theme "The Training of the Engineer" and, as a background, his work and experience in the revision of the engineering degree courses at the University of Durham lent an unusual interest and value to his remarks. Engineering is not a science but an art depending on science and, between the two, there are still many gaps, which the engineer has to bridge. His decisions have to be in a form capable of being translated into practice, and he has to be trained to make use of established scientific principles in conjunction with a knowledge of the needs of the world, of the natural forces to be contended with, of the properties of the materials to be used, of the capacities and limitations of those through whom the work has to be done and of the plant, tools, and machinery on which the processes depend. Prof. Hawkes indicated how the curricula at Durham have been revised to comply with these comprehensive demands. The more human aspects are provided for by weekly reports and discussions in college, and by the personal contact during the workshop training with men of all classes, perhaps the most broadening influence that could be found. By the limitation of available time, the graduate course is mainly confined to the study of scientific principles and their applications. Such subjects as economics, works organization and administration are considered preferably as post-graduate studies. Prof. Hawkes also took occasion to report the progress of research work at Armstrong College, which has been greatly fostered by the members of the Institution he was addressing.

Observatory for St. Albans High School for Girls

ON October 23, Sir Frank Dyson inaugurated at St. Albans High School for Girls the observatory recently bequeathed to the school by the late Dr. William Alfred Parr. Dr. Parr, a well-known amateur astronomer and past-president of the British Astronomical Association, resided in St. Albans during the last few years of his life, and had erected in his garden a small but well-equipped observatory, containing a four-inch clock-driven equatorial by Cooke, with a photo-visual object-glass, Evershed solar spectroscope and other accessories. The entire observatory, which is of wood, surmounted by a 10-foot revolving dome, was, with its small annexe, removed from Dr. Parr's garden during the summer, and re-erected in the school grounds near the new gymnasium, under the supervision of Dr. W. H. Steavenson. Following an address by Sir Frank to the staff and pupils, assembled in the latter building, the observatory was formally opened and dedicated with picturesque ceremony, the Dean of St. Albans, the senior science mistress and the head girl taking part.

Food and the Family Budget

THE Engineers' Study Group on Economics, which was formed towards the end of 1933 to investigate the economic and social problems presented by the co-existence of poverty and actual or potential plenty, has now published its investigations on family budgets in a pamphlet entitled "Food and the Family Budget" (Engineers' Study Group, Hazlitt House, Southampton Buildings, W.C.2. 1*s*. 6*d*.). This investigation has been confined to conditions as they exist in Great Britain to-day. The problem is treated quantitatively, and an attempt is made to deduce some general minimum standard of living which would be both desirable and practicable. The method used was that of analysing and comparing published data on family budgets, at the same time taking into consideration modern trends in consumption and requirements indicated by scientific research. The total budget required to provide the minimum standard desirable was found for a "statistical average family" of 3·72 persons to be about £6 per week (equivalent to about 63*s*. per week for each wage earner) and of this sum about 37*s*. a week would be required for expenditure on food. The suggested food budget is shown to be compatible with (*a*) the dietetic requirements laid down by the British Medical Association Committee on Nutrition; (*b*) actual national consumption; and (*c*) the increased consumption of home-grown foodstuffs that would raise the dietetic standard to a level adumbrated by Sir John Orr. There is little doubt, it is stated, that a large part of the population is suffering from lack of nutritious foodstuffs, particularly fresh dairy produce, fruit and vegetables.

Noise on the Road

THE Departmental Committee which was set up in 1934 by the Minister of Transport, under the chairmanship first of Sir Henry Fowler and afterwards of Dr. G. W. C. Kaye, to study the question of motor-vehicle noises, has issued its second interim report (London: H.M. Stationery Office. 1*s*. net). The report elaborates and extends the first report of the Committee, which dealt with new vehicles including motor-cars, sports-cars, motor-cycles and goods- and passenger-carrying vehicles. It appears from the report that a consensus of opinion considered that a loudness of ninety British standard phons represents in general a transition point between tolerably noisy vehicles and unduly noisy ones. Two types of tests are therefore proposed by the Committee: (*a*) normal-running tests in which a vehicle running under full throttle at 30 m.p.h. must not generate an overall noise exceeding 90 phons at 18 feet lateral distance; (*b*) racing-engine tests in which a stationary vehicle the engine of which is racing at maximum-power speed must not generate an overall noise exceeding 90 phons at 25 feet behind the open end of the exhaust pipe. A temporary tolerance limit is suggested for motor-cycles and commercial vehicles. In the meantime, the Minister has received an assurance from the manufacturers of motor-cycles and sports-cars, which are among the chief offenders on the road, that no new vehicle shall in future leave their works the noise of which can be regarded as offensive. The Ministry of Transport is proposing to set up six noise-testing stations to assist the industry in this laudable object. Meanwhile, work is proceeding on the production of a simplified objective noise meter so as to facilitate its production in greater numbers. Detailed results of the tests, which were carried out by the National Physical Laboratory, are given in the report.

Recent Acquisitions at the Natural History Museum

THE Museum has received as a permanent loan from His Majesty the King a fine series of elephant tusks. The series comprises the record pair of Indian tusks, three pairs and a single large tusk of the African species, and an ornamented tusk of the Malayan elephant. The Indian tusks, which are figured in Rowland Ward's "Records of Big Game", are of exceptional size for Indian ivory, measuring 8 ft. 9 in. and 8 ft. 6½ in. in length and weighing 161 lb. and 160 lb. respectively. Good Indian tusks rarely exceed 6–7 ft. in length or weigh more than 80–100 lb. The Trustees of the American Museum of Natural History, New York, have handed over to the National collection the type specimens of fifteen races of British and Irish birds, described by the late Dr. E. Hartert and Mr. H. F. Witherby. These types formed part of the famous Rothschild collection which was purchased by the American Museum in 1932. Through the generosity of Mr. E. C. Stuart Baker, the Museum has received the largest collection of birds' eggs ever presented to the British Museum. This great collection consists of approximately 50,000 eggs belonging to some 1,960 different species of birds found in the Indian Empire. Very many of these eggs were not previously represented in the national collection and in a considerable number of cases Baker's specimens are the only ones known. A collection of more than 6,000 invertebrates, chiefly Brachiopoda and Trilobita, including 40 new species, as well as type and figured specimens, collected by Mr. B. B. Bancroft with great exactness as to horizon and locality, from the Ordovician of the Welsh Borderland and the Lake District, has been purchased for the Department of Geology. The Mineral Department has received from the Director of the Geological Survey of Nigeria as a donation a piece, besides several fragments, of the meteoric stone which fell near Udei station, Benue river, Nigeria, in 1927. The meteorite is of unusual interest because it belongs to the rare pallasite group of stony-irons containing olivine.

THE Department of Botany has received from Mr. C. J. Brooks his fern herbarium, containing about 2,650 specimens. Mr. Brooks was employed as a chemist in the gold-mining industry in Sarawak and later in Sumatra, where he collected insects and ferns. He discovered many new species in the mountains of Borneo and Sumatra, including Gunong Dempo. He also visited Celebes and Amboina. In the latter island he made a very complete collection and ascended the volcano Salahoetoe. Mr. Brooks's plants were mostly worked out by Capt. C. R. W. K. van Alderwerelt van Rosenburgh at Buitenzorg, and many are types or paratypes not otherwise represented in Europe. He was also in touch with Prof. E. B. Copeland and the late Prince Roland Bonaparte, and obtained some specimens by exchange. Especially notable are a set of Schlechter's New Guinea ferns and some from Papua collected by the Rev. Copland King. His herbarium is the most valuable acquisition that the fern collections have had for many years, the more so as it comes from a region which was previously somewhat scantily represented. The Oxford University Exploration Club has presented the botanical collections made by Mr. H. G. Vevers on the recent expedition to Greenland. This comprises more than five hundred numbers. Dr. G. N. Humphreys of the Mount Everest (1936) Expedition has sent to the Museum a collection of 88 flowering plants which he made at the higher camps used by that Expedition. Considering the conditions under which Dr. Humphreys worked, the plants are very well collected and dried, and he appears to have obtained a good representation of the alpine flora. The Department has particularly fine collections from Nepal, and Dr. Humphreys' specimens will add further to the importance of this Himalayan material. A number of the species represented reach the altitudinal limit of flowering-plant vegetation, and it is particularly valuable to have the precise altitude at which each specimen was collected.

Colonial Territories and Economic Opportunity

THE Advisory Committee of the National Executive of the Labour Party has prepared a pamphlet on "The Demand for Colonial Territories and Equality of Economic Opportunity" in which the position of the three 'dissatisfied' Powers—Germany, Italy and Japan—is examined (Labour Party, Transport House, Smith Square, London, S.W.1. 4*d*.). In analysing access to raw materials, the division of the world, recently adopted by the *Economist*, into the British Empire, the French Empire, the Dutch Empire, the U.S.A., the U.S.S.R., and the rest of the world, is used. The general conclusion is reached that colonies are of some, but not of great, economic importance. Only in the case of rubber are the colonial possessions of a Great Power of dominant importance. It is held that the abolition of discrimination rather than the exchange of territories should be the objective. To this end, the Labour Party should advocate the bringing of Colonial possessions, such as those of Britain in Africa, under the mandates system—approximately of the present *B* Class of mandates. The pamphlet is full of information and deserves close study.

Teaching Electric Cookery in Switzerland

IN the *Electrical Age* of October, a magazine published by the Electrical Association for Women, an interesting summary is given of Swiss methods of teaching electrical cooking in schools. Swiss manufacturers supply special electric cookers for use in school kitchens. These are made to stand away from the wall so that access can be obtained from all sides. The oven is placed on one side instead of being put under the hot plates as in the ordinary domestic cooker. This facilitates access to it and at the same time provides standing place for cooking utensils on the top of the oven. The arrangements are such that the pupils can be conveniently divided into four groups. Each group is self-contained and has charge of a cooker with oven, table and washing-up arrangements, and a cupboard for utensils and crockery. The items of equipment are arranged as close together as possible and in the order in which they are required. In order to teach economy, the pupils are required to reckon up the total cost in materials and electrical consumption of all food prepared. A separate meter is usually installed in the circuit supplying each cooker. Although rarely used in schools, descriptions are given of the tilting cauldron and the tilting oven often used in hotels and institutions. The cauldrons, instead of having a tap for withdrawing the contents, are arranged to tilt and pour out the contents over a wide lip. They are mounted on trunnions and worked by a worm gear so that the tipping is done gradually without the risk of spilling. They can be kept clean as easily as a basin, and the heat control is such that even milk cannot boil over.

Agricultural and Horticultural Pests

MUCH recent research into the incidence and overwintering of the potato blight fungus (*Phytophthora infestans*) has made it necessary for the Ministry of Agriculture to revise its leaflet upon this subject. The new Advisory Leaflet, No. 271, shows that the fungus overwinters upon infected tubers, and there are usually sufficient of these left from previous crops, or thrown out from storage pits, to begin fresh infection in the spring. Control by spraying and dusting is described, and other methods include the removal and destruction of haulm before digging the crop, and the disposal of blighted tubers. Advisory Leaflet No. 273 replaces leaflet No. 195, and deals with American gooseberry mildew (*Sphærotheca mors-uvi*). The subject-matter has been brought up to date. A short Advisory Leaflet (No. 182) deals with spurrey (*Spergula arvensis*) as an agricultural weed. Spraying with 5 per cent solution of copper sulphate, or 7–10 per cent sulphuric acid, are recommended for control of the weed amongst cereal crops, in addition to the application of lime, and other methods.

Medallions of Manganese Steel

WHEN King Edward, as Prince of Wales, visited the Hecla Works of Hadfields, Ltd., some years ago, he cast a medallion portrait of himself in manganese steel. A similar medallion, 20 inches in diameter, was recently cast showing the head and shoulders of General the Right Hon. J. C. Smuts, P.C., and both are now on view at the Johannesburg Empire Exhibition, of which General Smuts is honorary president. The manganese steel of which these medallions are made is run into the moulds at a temperature of about 1,450° C., but despite this high temperature, and owing to the specially developed moulding sand employed, the definition of the features is remarkable, each detail being reproduced as clearly as in a photograph.

Faraday House Journal

WITH the opening of the Michaelmas term at Faraday House Electrical Engineering College, *Faraday House Journal* makes its reappearance and, in addition to the usual personal, social and collegiate items, the present number contains several short papers of note. The principal, Dr. A. Russell, writing under the title "Unfettered Mathematics in Engineering", continues his articles on capacitance coefficients, and here shows that the capacitance of a system of two external spheres can be expressed in terms of certain spherical condensers, the values of which can readily be found. In a paper "On a Natural System of Absolute Physical Measurement", Sir Ambrose Fleming puts the case for, and gives data relative to, a system based on the rest mass of the nucleus of the hydrogen atom and the wave-lengths and periodic times of certain of its radiations. "Fluorescence under Ultra-Violet Light" by Dr. W. R. C. Coode-Adams and "Perspective" by the Rev. L. Van Vestraut complete this section of the contents and their titles sufficiently indicate the nature of these two papers.

Bureau international des Poids et Mesures

DR. CHARLES-EDOUARD GUILLAUME, director of the Bureau international des Poids et Mesures, is retiring after fifty-three years in the service of metrology. The permanent administrative committee of the International Committee of Weights and Measures, which consists of Prof. V. Volterra of Rome (president), Prof. B. Cabrera of Madrid (secretary), Prof. P. Janet of Paris, Prof. P. Zeeman of Amsterdam, and Dr. C. E. Guillaume, has nominated M. Albert Pérard, assistant-director of the Bureau, to succeed Dr. Guillaume. M. Pérard, like his predecessor, has spent all his life at the Bureau; he is best known for his work on the metrology of the interference of light. The Bureau, the oldest of the international scientific organizations, is at the Pavillon de Breteuil, Sèvres, Seine-et-Oise; since the signature of the Convention of the Metre in 1875, it has been under the direction in turn of G. Govi, O. J. Broch, J. R. Benoît and Dr. Guillaume.

New Midwives' Service

A CIRCULAR on the Midwives Act, which has recently become law, has been issued by the Minister of Health (Circular 1569. London: H.M. Stationery Office. 6*d*. net). The Act marks an important advance in the policy of improving the public health services of Great Britain, and should do much to improve the maternity services, and secure a reduction in the present rate of maternal mortality. The Act aims at providing every prospective mother whose baby will be borne at home with the services of a trained midwife for her confinement and fourteen days thereafter. The new arrangements should also do much to improve the status and prospects of midwives who enter the new service. The Circular, which is addressed to the local authorities administering the Act, contains a memorandum fully explaining the provisions of the Act.

Leonard Darwin Scholarship of the Eugenics Society

THE Eugenics Society has established a second Leonard Darwin scholarship, which is to be devoted to the investigation of racial crossing. The first holder is J. C. Trevor, a graduate of Oxford in anthropology, who has spent the last two years studying mixtures of negro and white stocks in the United States, with the aid of a Commonwealth fellowship. He has collected ethnological material in the Virgin Islands and in East Africa, and with Dr. Dudley Buxton has made an investigation of English medieval skulls. He has also a collection of biometric material on West African and American negro crania. Mr. Trevor will devote a year to a survey of the literature on the subject of inter-racial crossing.

Another New Star in Aquila

THE Swedish observer, Mr. Nils Tamm, who discovered a nova of magnitude 8 in Aquila last month, has now detected another of these bodies in the same constellation. The latest nova was announced on October 20 as having been found on a plate taken on October 7, when the magnitude is stated to have been 7·0. Dr. W. H. Steavenson, who gives the position of the nova for 1936·0 as R.A. $19^h\ 23^m\ 28{\cdot}16^s$, North Decl. 7° 28′ 32·5″, finds the magnitude to be about 8·0, with little fading between October 21 and 25. He reports the colour as being fiery red. In the spectrum the red line of hydrogen (Hα) is very bright and prominent, and contributes a large proportion of the total visual light of the nova. Tamm's earlier nova is still of about the eighth magnitude, after undergoing some marked fluctuations since its discovery. The two novæ can just be seen simultaneously in a good prism binocular, being only a little more than six degrees apart.

The Night Sky in November

AT the beginning of the month, the duration of night (defined as the interval from sunset to the following sunrise) is 14·4 hours, and at the end of the month 15·9 hours in the latitude of London. The moon is new on November $14^d\ 4{\cdot}7^h$ and full on November $28^d\ 16{\cdot}2^h$ U.T. Occultations of stars brighter than magnitude 5 occur on November 28–29, when κ Tauri reappears at $17^h\ 30{\cdot}6^m$ and τ Tauri disappears at $23^h\ 48{\cdot}4^m$ and reappears at $1^h\ 0{\cdot}2^m$. The planet Venus sets this month in the early evening, and at sunset is low in the south-west. Jupiter is in the same region of the sky, and on the evening of November 12 will be found about 2° above Venus. The near approach of these two bright objects (actual conjunction takes place on November $13^d\ 12^h$) will be well worth looking for at nightfall on November 12 and following with telescopic aid about midday on November 13. Mars is a morning star of magnitude about + 1·8. Saturn is above the horizon during the first part of the night; on November 15 it sets just before 1^h. Watch may be kept on November 15–16 for a possible display of the Leonid meteors. This shower, the radiant point of which is at R.A. $10^h\ 0^m$, Dec. + 22°, is generally visible every November, but at epochs of every 33 years it yields, with some exceptions, an unusually brilliant display. The last great shower was due in 1932, but in Great Britain it failed to come up to expectations, though at one station in the United States as many as 240 meteors were observed in an hour. November 19–20 is the date of maximum of the Andromedids, a shower associated with the lost comet of Biela; the radiant of the shower is not far from the star γ Andromedæ. (Near ν Andromedæ may be seen, with the naked eye, a tiny, faint hazy patch which is the Andromeda nebula, distant 870,000 light years.) The light variations of Algol (β Persei) can be observed at about the following times: November $8^d\ 2^h$, $10^d\ 23^h$, $13^d\ 19^h$, $28^d\ 4^h$ and December $1^d\ 0^h$. In mid-November at about 22^h, the constellations Cassiopeia, Perseus, Andromeda, Aries and Cetus are on or near the meridian, but the eastern half of the sky, rich in first magnitude stars and led by the Pleiades, will probably claim the observer's attention.

Announcements

THE Right Hon. Lord Rutherford will deliver the twelfth annual Norman Lockyer Lecture of the British Science Guild at the Goldsmiths' Hall, Foster Lane, London, E.C.2, on November 12 at 4.30 p.m. The title of Lord Rutherford's lecture will be "Science in Development". This is the last occasion upon which the Norman Lockyer Lecture will be arranged by the British Science Guild as an independent body. In future the lecture will be carried on under the auspices of the British Association. Tickets for Lord Rutherford's lecture are obtainable, free of charge, on application to the Secretary, British Science Guild, 535–7 Abbey House, Victoria Street, London, S.W.1.

SIR THOMAS HOLLAND will deliver the Huxley Lecture at the Imperial College of Science and Technology on May 4, 1937, at 5.30 p.m. The subject of Sir Thomas's lecture will be "The Permanence of Oceanic Depressions and Continental Elevations".

PROF. S. CHAPMAN, chief professor of mathematics in the Imperial College of Science, has been elected a member of the Kaiserlich Deutsche Akademie der Naturforscher, Halle, in recognition of his researches in terrestrial magnetism.

THE Chadwick Gold Medal and Prize for excellence in municipal engineering and hygiene was presented to Mr. E. A. Drew, of University College, London, on October 27.

AT the annual statutory meeting of the Royal Society of Edinburgh held on October 26, the following Council was elected: *President:* Prof. D'Arcy Wentworth Thompson; *Vice-Presidents:* Principal O. Charnock Bradley; Prof. P. T. Herring; the Marquis of Linlithgow; Prof. E. B. Bailey; Prof. F. A. E. Crew; and Lieut.-Col. A. G. M'Kendrick; *General Secretary:* Prof. James P. Kendall; *Secretaries to Ordinary Meetings:* Dr. A. C. Aitken and Dr. C. H. O'Donoghue; *Treasurer:* Dr. James

Watt; *Curator of Library and Museum:* Dr. Leonard Dobbin; *Councillors:* Principal J. C. Smail; Sir Harold J. Stiles; Prof. J. Walton; Prof. Edwin Bramwell; Prof. T. H. Bryce; Prof. I. de Burgh Daly; Mr. J. A. Inglis; Prof. A. D. Peacock; Dr. J. E. Mackenzie; Prof. Sydney Smith; Prof. Ralph Stockman; and Dr. E. Maclagan Wedderburn.

A BRONZE bust of Dr. Emile Roux was recently unveiled at Angoulême, where addresses were delivered by Prof. Marchoux, representing the Paris Academy of Medicine, and Dr. Louis Martin, Roux's successor at the Pasteur Institute.

A PAN-RUSSIAN scientific institute for the study of the bacteriophage has been erected at Tiflis, and will be opened next year under the direction of Prof. F. d'Hérelle.

AT the ninety-fourth Congress of the Society of German Men of Science and Physicians, recently held at Dresden, a German Society of Hygiene was founded under the presidency of Prof. Hans Reiter, president of the Health Office of the Reich.

THE Argentine Government has formed a national committee of intellectual co-operation with the object of promoting intellectual co-operation with different countries in science, literature, art, education, etc. The committee will enter into relations with the International Institute of Intellectual Co-operation in Paris and the International Office of Education at Geneva.

MESSRS. JAMES TREGASKIS AND SON, of 66 Great Russell Street, London, W.C.1, in their Caxton Head Catalogue, No. 1023, are offering for sale some interesting Newton papers. This includes John Flamstead's "Historia Cœlestis", a collection relating to the "Historia Cœlestis" published by Newton and Halley without the consent of the author; a letter by Newton to Sir Richard Onslow; Newton's signature on an oblong vellum document; a letter from Menschikoff to Newton concerning the former's fellowship of the Royal Society, together with three autographed drafts of Newton's reply; a note on the calculus by Newton; several letters on the calculus; and a letter to Newton from John T. Desaguliers, inventor of the planetarium.

THE Imperial Council of Agricultural Research, Simla, announces that there is a surplus stock of certain agricultural and veterinary publications for free disposal (packing and carriage to be paid by the indentor). The following are listed: Handbooks of Commercial Products (17 different volumes); Catalogue of Indian Insects (parts 1–22, part 11 excepted); Proceedings of the Board of Agriculture in India (1906–29—series incomplete). The number of copies available is limited, but in the case of the Commercial Handbooks is quite considerable. Application for any of these publications should be made to the Manager of Publications, Civil Lines, Delhi, on or before November 30.

ERRATUM. In NATURE of October 3, p. 589, in the letter entitled "A New Strigeid Parasite of the Rare Genus *Cyathocotyle*", for "*Cyathocotyle calvusi*" read "*Cyathocotyle calvi*".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An assistant engineer in the Roads Department of the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, London, S.W.1 (October 31).

An assistant (Grade II) (physics or engineering) in the Signals Experimental Establishment, Woolwich Common, S.E.18—The Superintendent (November 2).

An assistant lecturer in mechanical engineering, and a workshop instructor in Coventry Technical College—The Director of Education, Council House, Coventry (November 6).

An assistant physicist in the Radiotherapy Department of the Middlesex Hospital Medical School, W.1—The Dean (November 9).

AN assistant (man) in the Technical Education Branch and a woman organizer of instruction in domestic subjects in the Education Department of the West Riding of Yorkshire—The Education Officer, County Hall, Wakefield (November 9).

A University reader in mechanical engineering in King's College, London—The Academic Registrar, University of London, W.C.1 (November 10).

An Imperial mycologist at the Imperial Institute of Agricultural Research, Pusa, Bihar, India—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (November 10).

A metallurgical inspector in the Indian Stores Department—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (November 13).

A principal of Twickenham Technical Institute—H. M. Walton, 10 Great George Street, Westminster, S.W.1 (November 14).

A technical officer (ref. A. 263) and assistants (Grade III) at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (November 14).

A lecturer in experimental zoology in the University of Edinburgh—The Secretary (November 21).

A St. Mungo professor of pathology in the University of Glasgow—The Secretary to the University Court (November 26).

A principal of the Farm School and Officer-in-Charge of the School Farm and Experimental Station in the Department of Agriculture, Peradeniya, Ceylon—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1 (November 30).

An assistant research chemist at the British Drug Houses, Ltd., Graham Street, City Road, N.1—The Secretary.

An executive engineer in the Public Works Department of the Government of Sierra Leone—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (quote *M*/4572).

A reader in bacteriology in the Department of Pathology, University of Oxford—The Professor of Pathology.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 764.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

The Hydrogen Bond and the Structure of Proteins

IN a theory put forward in these columns in March last[1], it was suggested that the molecule of simple native protein may contain closed polypeptides: that the polypeptides, open or closed, fall into rings: and that the ring system is such as to allow the possibility of a regular and orderly arrangement of hundreds of amino and imino acid residues which, to some extent at least, is independent of the particular residues in the molecule. These suggestions, as was clear from the outset, can be given precise formulation in more than one way. Two in particular seemed worthy of detailed consideration.

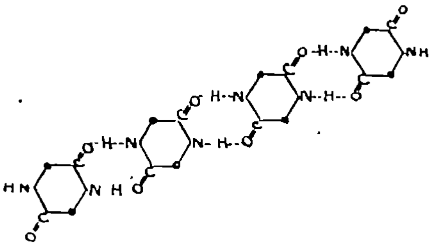

FIG. 1.

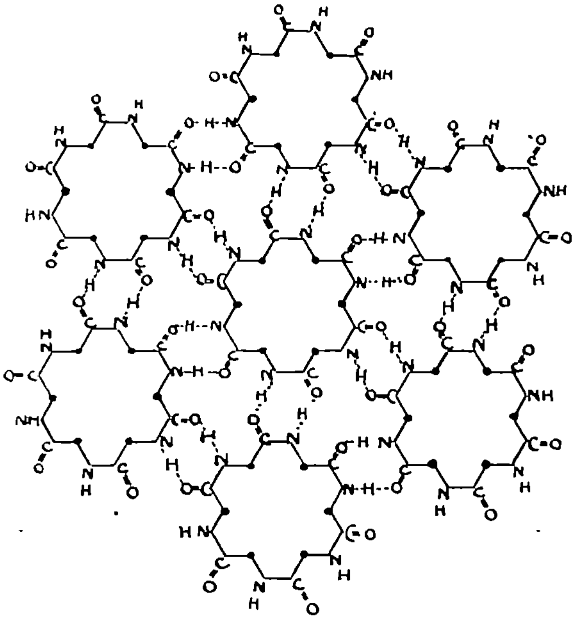

FIG. 2.

In the previous communication the formulation was in terms of the cyclization of polypeptides and the polymerization of diketopiperazines and other closed polypeptides by means of the intra- and intermolecular lactam-lactim transformation

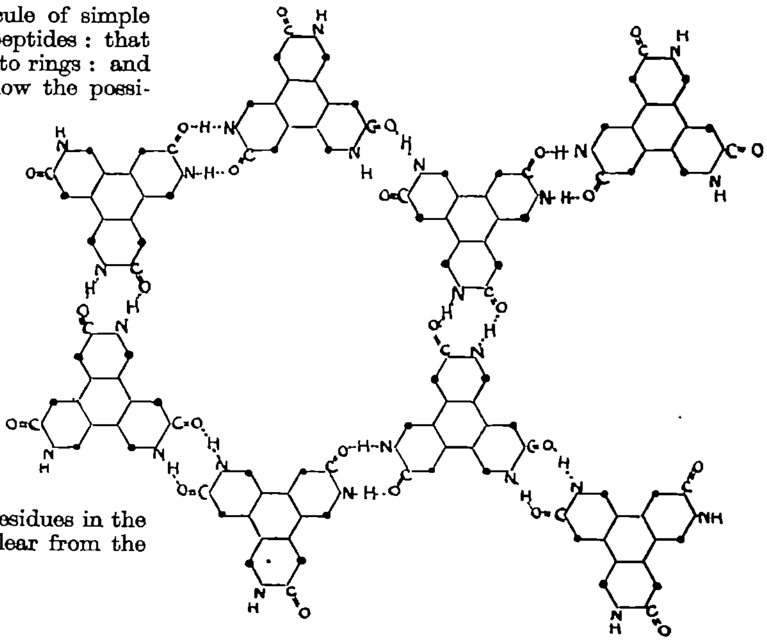

FIG. 3.

$$\rangle C=O\ H-N\langle\ \rightleftarrows\ \rangle C(OH)\ -N\langle$$

This postulate, that polypeptides cyclize and polymerize by means of this transformation into laminar molecules, carried with it the deduction that lamina may be linked to lamina by hydroxyl bonds[2], a conclusion in good accord with many facts as to the behaviour of proteins, for example, capacity for hydration[3].

In the present communication, a correlative interpretation in terms of hydrogen bonds[4]—which have a close relationship to hydroxyl bonds—is presented for consideration.

The suggestion that hydrogen bonds play a part in the structure of the protein molecule was put forward by Jordan Lloyd in 1932[7] and 1933[5], and afterwards by many writers, in particular Mirsky and Pauling[6] who, in a paper of great interest, have shown that it throws considerable light upon the phenomena of denaturation and floculation of proteins. This postulate can be developed very much on the same lines as the lactam-lactim postulate. Using the hydrogen bond as the mechanism whereby closed polypeptides may polymerize, we can build a linear polymer from substituted diketopiperazines (Fig. 1). Similarly, the hexapeptide anhydride can build a surface polymer (Fig. 2). Mixed polymers may also be constructed. Hydrogen bond polymerization (like lactam-lactim polymerization) thus allows the construction of laminar molecules of considerable extent having characteristic densities and characteristic lacunæ. The laminæ need not be plane. The use of hydrogen bonds also for intra-molecular links in polypeptides is under consideration.

In putting forward the two postulates we would stress the fact that there is no conflict between them. Indeed the formation of a hydrogen bond may be an intermediate step in the lactam-lactim transformation. Further, the hydrogen bond can be the mechanism of polymerization not only of polypeptides such as those shown in Fig. 2 but also of the cyclized polypeptides which are derived from the earlier postulate, for example, of cyclol 6, as shown in Fig. 3. It may also be pointed out that these postulates yield deductions which lend themselves to testing by experimental methods. As an example we take the deduction that individual protein films have characteristic lacunæ—and so characteristic permeabilities—and characteristic densities.

Reaction Kinetics and the Walden Inversion

DESPITE forty years of research, much mystery still surrounds the conditions determining the occurrence or non-occurrence of the Walden inversion. This is partly due to the difficulty of relating rotation to configuration; but it is due even more to the evident circumstance that these conditions must be intimately connected with the mechanism of substitution: it is only in comparatively recent years that the mechanism of aliphatic substitution has been fruitfully studied. In this field, mechanism has revealed itself principally through the examination of reaction kinetics; and by this means mechanism has been brought into intelligible relation with the structures of reactants and the conditions of reaction. For details we may refer to an early note in NATURE[1], and to a number of papers on the subject which have since appeared mainly in the *Journal of the Chemical Society*. It is an obvious sequel to apply the same weapon, the study of kinetics, in attacking the problem of the Walden inversion; for it should certainly be possible to trace a connexion between inversion and kinetics, and thus, with the aid of the knowledge already gained, to relate inversion to mechanism and its determining factors, structure and conditions.

This was our point of view a year ago when we commenced this method of approach. It is now no longer hypothetical that kinetics is able to link inversion with mechanism of substitution, and thus with structure and conditions.

It is not the purpose of this note to summarize interim results, the presentation of which would require too much space: our primary object is to direct attention to a highly effective method of investigating this problem. It seems appropriate, however, to give in outline a single illustration of the type of observation which in our view supplies the missing link in the argument connecting the occurrence of inversion with structure and conditions.

The hydrolysis of optically active α-bromopropionic acid was studied by E. Fischer[2], who obtained lactic acids of opposite sign of rotation according to whether he used silver carbonate or potassium hydroxide; much discussion has been based on this contrast, especially since in the case of some other halogeno-acids the two reagents give products having the same sign of rotation. Now Fischer was not in a position to know what we were able to predict from the electrical properties of the groups concerned, namely, that the α-bromopropionate ion is a critical structure for hydrolysis: the rates of halogen-ionization and of bimolecular replacement being comparable, it is possible to make either the unimolecular or the bimolecular mechanism dominant by changing the concentrations. He could not know either that in his hydrolysis with potassium hydroxide he was working in the range of the bimolecular mechanism, which, with moderate dilution, would have given place to the unimolecular mechanism; or that unimolecular hydrolysis would have given the opposite result, and, therefore, the same result as silver carbonate. In the scheme

$$\begin{array}{c} l\text{-}\alpha\text{-Bromopropionic} \\ \text{acid (as anion)} \end{array} \left\{ \begin{array}{l} \textit{Unimolecular } l\text{-Lactic acid } (S_N1) \\ \textit{Bimolecular } d\text{-Lactic acid } (S_N2) \end{array} \right.$$

the prefixes refer to configuration, signs of rotation being in this case oppositely related.

The principles underlying the dependence of inversion (including racemization) on the kinetics of substitution were considered in a previous paper[3]. The hydrolysis of α-halogeno-acids is one of the cases in which the two mechanisms, S_N2 and S_N1, lead to stereochemically different forms, and the identity or non-identity of the hydroxy-acids obtained with the aid of silver oxide and potassium hydroxide depends jointly on the constitution of the halogeno-compound and on the mechanism of the substitution. Several experimental studies of the nature illustrated have now been completed and will shortly be published, together with a general survey of the relevant theoretical principles.

Linkage in Man

SINCE hæmophilia and colour-blindness are both sex-linked conditions, the genes determining them may be expected to show linkage. That is to say, if a hæmophilic is colour-blind the majority of his hæmophilic relatives should be colour-blind, and the majority of his non-hæmophilic relatives should not be so. Similarly, if a non-hæmophilic brother of a hæmophilic is colour-blind, a majority of his hæmophilic brothers and other relatives should not be colour-blind; a majority of his non-hæmophilic brothers should be colour-blind, while most of his sisters should be transmitters of hæmophilia or colour-blindness, but not of both or neither.

To the two existing pedigrees showing both of these diseases we have added four more. The existence of linkage is established. The probability that our results are due to chance is less than 4×10^{-6}. For example, in one pedigree the three living hæmophilic relatives of a colour-blind hæmophilic, namely, a brother, a first cousin twice removed, and a second cousin once removed, were also colour-blind, while five male relatives who might have been, but were not, hæmophilic, had normal vision.

In the six pedigrees there was one case of crossing-over, a colour-blind hæmophilic having a colour-blind non-hæmophilic brother. There had been 28¾ opportunities of crossing-over, so the frequency of crossing-over (after allowing for certain small corrections) is as likely to be below as above 5 per cent.

A full account will be published elsewhere. We have to thank a number of colleagues, and particularly Drs. Birch, Macfarlane, Madlener, Riddell and Wright, and the Medical Research Council, for their assistance. We should like particularly to acknowledge the cordial co-operation of many members of the families concerned.

Distortion of Iron and Molybdenum

THE recent communication in NATURE by Túry and Krausz[1] may be helpful regarding work on the plastic distortion of metals and, in particular, on the nature of the yield point. In their letter, Fig. 1, No. 2, shows a load-extension curve for molybdenum wire after a certain treatment and involving the use of nitrogen at 1,300° C. for 20 sec. This curve closely resembles the well-known load-extension curve for iron and soft steel, apart from a horizontal portion at the top of the curve. Fig. 1, No. 1, shows a curve for wire treated in hydrogen only, but no such yield point is shown in this case. The shape of the curves may be partly due to the different treatments affecting the crystal size, and it would be useful to know the size of the crystals in the wire and to know the behaviour of iron wire after similar treatments. In this connexion, data[2] given by Arrowsmith for 'Armco' iron show that for material in which the crystal width was approximately 0·11 mm. did not have a marked yield point, but for a crystal width of approximately 0·07 mm. there was a considerable yield. Curves given by Edwards and Pfeil[3] suggest that for aggregates of iron crystals the marked yield may not occur when the crystals are wider than approximately 0·25 mm. or 0·4 mm.

In iron and soft steel, the remarkable yield is associated with the Piobert effect[4] (also known as Lüders' lines) which has also been reported, but much less frequently, as occurring in non-ferrous metals (for example, in aluminium and copper, but I believe that the distortion may be rather different in such cases because of the absence of the marked yield, though possibly related). It has been attributed to the presence of a second constituent in the structure and, on the Continent, to the presence of thin films of cementite at the boundaries of the ferrite crystals forming a strong network of cementite. The network was assumed to take the applied load for stresses up to the yield point, at which it broke down, thus releasing the load on to the weaker and more ductile crystals of ferrite which, as a result, extended immediately.

This I believe to be unlikely for several reasons[5] and that, so far as is known, it seems probable that the yield in aggregates of iron crystals (Piobert effect) is due primarily to the mode of distortion of the single iron crystal together with small crystal size, and that the effect may occur in aggregates of crystals of other metals provided that the mode of distortion of the single crystal of the metal resembles that of iron, and that the crystals be very small. (Crystal size may be of great importance. Thompson and Millington[6] attributed the distortion associated with the marked yield to certain kinds of motion in the body-centred cubic crystal, but it may occur in metals of dissimilar lattice because of the apparently unknown influence of crystal size.) Further, the effect shows a ready response of the aggregate of iron crystals to distort in a general way according to the internal distribution of stress, and it seems that the *transmission* (which results in the yielding) of the distortion throughout the aggregate is facilitated by the large number of planes in the body-centred cubic latticed crystals of iron on which slip may occur, and also, if body-centred cubic crystals can distort on planes (those of maximum shear stress) other than crystal planes[7], and again by crystal size.

This *transmission*, without 'jamming' as it were, would happen, presumably, if the crystal size be not too big or if the capability of the individual crystals to collaborate with the influence of the general stress distribution be relatively unlimited. (Of the possible slip-planes in iron there appear to be at least three types, {110}, {112} and {123}, and the number of types appears generally to be more than for other metals, whilst for β-brass the types appear to be {110} and {112}. By symmetry, there are a large number of planes, some of which will be possible slip-planes in virtue of their proximity to the planes of maximum shear stress.)

A thorough investigation of the distortion associated with the Piobert effect in soft steel, using X-ray diffraction methods, is in progress here and, as yet, reveals distortion in the crystals, but without the appearance of 'preferred' orientation of crystal planes, and suggesting that the distortion within the aggregate is complex. Present work also consists in examining the properties of aggregates of very small crystals. C. F. Elam (Mrs. G. H. Tipper) concludes that there is no material difference between facts ascertained about the distortion of single crystals of iron and β-brass[7]. Attempts were made here during the summer of last year to produce the Piobert effect in aggregates of body-centred cubic latticed crystals of β-brass, but the desired smallness of crystal size could not be produced, which was unfortunate; so work on molybdenum, rather than tungsten (both of similar lattice as the brass), has already been started.

Simultaneous Transmission and Reception of Radio Waves

WE have succeeded in operating a valve receiver R_1 and a valve transmitter T_1 both working on the same antenna, and during their operation, receiving through R_1 another distant transmitter T_2, working on exactly the same frequency as T_1. This has been done by a device making use of simultaneous modulation of T_1 and R_1.

The frequencies used are about 11 megacycles per sec. for the carrier waves of T_1 and T_2, and 750 cycles/sec. for modulation. We have also worked with lower frequencies, for example, a carrier wave of 1 megacycle/sec. and modulation frequencies of 50–16,000 cycles/sec.

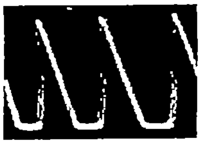

FIG 1.

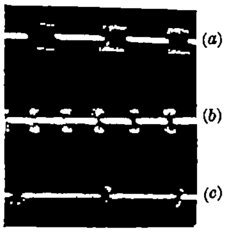

FIG. 2.

A special wave-form of modulation other than the common sinusoidal wave has been advantageously used for this purpose. This wave-form as well as the transmitted groups of waves can be observed during actual work, by a cathode ray oscillograph. Fig. 1 is from a photograph of such a wave-form used for modulation (frequency 750 cycles/sec.) Fig. 2*a* shows a pattern of transmitted groups of waves of a frequency one megacycle/sec. modulated by 750 cycles/sec.; Fig. 2*b* is the same pattern as Fig 2*a* modulated at double frequency, that is, 1,500 cycles/sec.; Fig. 2*c* is the same pattern as Fig. 2*a*, but using for the transmitting valve a high negative grid-bias near to the point at which the modulated transmitter T_1 stops oscillation.

Owing to the development of short-wave technique, this problem of simultaneous transmission and reception may form the basis of many future scientific and technical applications.

A Cosmic Cyclotron as a Cosmic Ray Generator?

MANY hypotheses have been propounded regarding the origin of cosmic radiation, but none of them seems to be able to account for the enormous energies found. In this note I shall try to show that a double star may constitute a gigantic cyclotron, which can give rays with energies of the right order of magnitude.

Let us assume that a charged particle (for example, an electron) moves in the magnetic equatorial plane of a star. If the field is H (equal to a constant multiplied by R^{-3}), the particle moves in a small circle with radius ρ which has a precessional movement around the star in a circle with radius R (Fig. 1). The angular velocity of the precession is

$$\omega=\frac{3}{2}v\frac{\rho}{R^2},$$

where v is the velocity of the particle. If v is very near c, the velocity of light, we have $\rho = V/300H$, if eV is the energy of the particle in electron volts. Then we get:

$$\omega=\frac{c}{200\,R^2}\;\frac{V}{H} \qquad . \; . \; . \quad (1)$$

We now assume that a planet, or a second star, rotates around the first star, with the same angular velocity ω. Then an electric field F (deriving from a difference of potential between the stars or from the rotation) can constantly increase the energy of the particle in the same way as a rotating electric field accelerates ions in a cyclotron. When the energy of the particle increases, R is diminished and the particle seems to be in a rather stable equilibrium in relation to the rotating system.

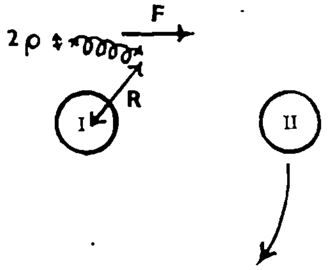

FIG. 1

The maximum energy of the particle can be calculated from (1). If R is 7×10^{10} cm. (about the radius of our sun) and H is 50 gauss (about the magnetic field at the surface of the sun), and further, $\omega = 0{\cdot}5 \times 10^{-4}$ sec.$^{-1}$ (a reasonable value for the rotation of a double star), we get

$$V \sim 10^{11} \text{ electron volts},$$

which is of the order of magnitude of the energy of the bursts.

Wilhelm von Waldeyer

IN the note on Wilhelm von Waldeyer in NATURE of October 3, p. 579, there appears the statement that this German anatomist was the first to describe the neurone theory. Most discoveries have been based on the work of previous investigators, and there is much useless discussion on priority concerning almost every great contribution to pure or applied science. In the present instance, however, a survey of the relevant literature readily shows that Waldeyer's only significant contribution to the neurone theory with which his name is so often linked was the introduction of the term 'neurone'.

The doctrine that the nervous system is formed of cells is a corollary of the cellular theory of Schwann and Schleiden. Leeuwenhoek and Malpighi saw cells ('globuli') in the cerebral cortex and, so early as 1741, Swedenborg, in his "Oeconomia Regni Animalis", described the cortical cells and their supposed functional importance in a manner surprisingly similar to the views which are now held. Waller's work (1850) on the degeneration of nerve fibres showed the trophic influence of the nerve cell on the fibre. Deiters, in 1865, showed that each nerve cell possessed an axis cylinder and dendrites. His

(1886) established the fact that nerve cells are derived from columnar ectodermal cells and are, therefore, almost certainly autonomous cellular elements themselves. He wrote: "Als festehendes Princip vertrete ich dabei den Satz : dass jede Nervenfaser aus einer einzigen Zelle als Ausläufer hervorgeht. Diese ist ihr genetisches, ihr nutritives und ihr functionelles Centrum ; alle anderen Verbindungen der Faser sind entweder nur mittelbare oder sie sind secundär entstanden."

Golgi's introduction (1873) of the method of silver impregnation provided an elegant technique for the study of the nervous system and, although Golgi himself mixed considerable *a priori* reasoning with his objective findings, Forel, of Zurich, used Golgi's results as the basis of a vigorous appeal for the application of the cellular theory to the nervous system.

It is to Ramon y Cajal, however, that we owe most of the fundamental data on which the neurone doctrine rests. He established, by work which must for ever be of basic significance, the conception that "the nervous system is built up of conductive chains of individually distinct and discrete conducting nerve-cells". It was this conception which Waldeyer called the neurone doctrine, and only too frequently in the literature is the credit for its establishment given to him. Sir Charles Sherrington, in his Royal Society obituary notice of Cajal, has presented the real position admirably. He writes : "The doctrine was his chief life-work and he felt it his due that it should be recognised as his. In his Memoirs, in each edition, he reverted to it : 'that which, and all that, Waldeyer did was to publish in a weekly newspaper a résumé of my research and to invent the word *neurone*'. Cajal had reason to feel hurt ; the injustice is unaccountable. Not at any time had the researches of Waldeyer touched the subject. He had not contributed either to the discoveries or to the generalisation".

The Red Blood Corpuscles of Primitive Mammals

ALTHOUGH the investigations of Weidenreich, Lohner, and Jordan, and the more recent studies of Arey and Ponder have led to considerable discussion concerning the actual form of the red corpuscles in the circulating blood of the Eutheria, it has long been recognized and generally accepted as an established fact that the mature erythrocytes are non-nucleated in all groups of the Mammalia.

Whilst subscribing to this view, Rogers[1] has brought forward the suggestion that at least two mammals (llama and echidna) possess red blood corpuscles which do not conform to this condition in their adult stages.

Rogers's statement, made in the course of a discussion on the transport system in the vertebrates, that "In all the mammals, with the possible exceptions of Llama and Echidna, they (that is, the erythrocytes) are non-nucleated", led me to prepare and examine a series of blood smears from the primitive Prototheria. These animals, confined entirely to the Australian region, are represented by a single living order, the Monotremata, including the duck-bill or platypus (*Ornithorhynchus anatinus*) and the spiny anteater or echidna (*Tachyglossus aculeatus*).

I am not in a position to offer any personal observations on the blood of the llama, but an abstract in French by Robert Tissot, of Biffi's paper "Alcune osservazioni sul sangue del lama", states that "Les erythrocytes du lama sont elliptiques et biconvexes ; leur forme est donc celle des verres de lunettes pour presbytes ; ils ne sont pas nucléés".

The red blood corpuscles of platypus and echidna are typically mammalian in form, being non-nucleated, biconcave discs. An examination of the mature erythrocytes from the blood of echidna clearly disproves Rogers's contention that the red corpuscles of this primitive mammal were possibly exceptional in regard to their structure. The suggestion that these corpuscles might prove to be nucleated is, therefore, without foundation.

Analysis of Tissues for Metallic Content

REFERENCE was made in a previous letter[1] to the occurrence of nickel and cobalt in a number of plant and animal tissues and in some New Zealand soils, and also to the vital part cobalt has been found by workers in Australia to play in the lives of sheep. The location and function of cobalt in sheep were not known, and efforts have been directed to discover in which tissues of the sheep cobalt is normally present.

Ordinary direct spectrographic analysis of tissues by the oxy-coal gas flame method gave no indication of cobalt or nickel, and experiments were made on quantities of 50–100 gm. of wet tissues, using chemical methods to extract and partially to separate the metals before analysing them spectrographically. The results obtained indicate that this method has wider applications and will give new information regarding the relations between healthy life and the mineral content of the soluble (chemically active) and insoluble (physically active) parts of tissues. Experiments made with sheep's liver, spleen and heart, show that hydrochloric acid of about normal strength, acting at room temperature for 18–24 hours, extracts the alkalis, magnesium, zinc, manganese, nickel, etc., with only a small portion of organic matter, and that calcium, copper and iron are only partially extracted from the much larger part of the tissue which remains.

The best procedure found so far has been to digest 100 gm. coarsely cut tissue with a mixture of 100 c.c. of water and 15 c.c. of strong hydrochloric acid. Filter next day, evaporate to low volume and add successive quantities of 2 c.c. nitric acid and some hydrochloric acid, so long as any marked action is apparent : keep the hydrochloric acid in excess at the end to expel the nitric acid, dilute and filter. A mixture (about 1 drop for healthy to 10 drops for diseased livers) of resinous and oily compounds remains on the paper ; the former retains traces of copper, silver, etc., and a small precipitate sometimes separates from the filtrate on cooling, which may contain lead and calcium. The liquid is diluted to about 80 c.c., making it weakly acid, and is precipitated, filtered, etc., successively with (1) hydrogen sulphide, (2) ammonium acetate after oxidizing iron, (3) hydrogen sulphide, that is, in acetic acid, and

(4) after adding hydrochloric acid, with potassium ferrocyanide. All the reagents used can be obtained free from metallic impurities.

As examples of the results obtained, calcium was reduced in sheep's liver (all tissues being dried on filter paper to remove oil) from 0·10 to 0·04 per cent; copper from 0·05 to 0·035 per cent; and iron from 0·03 to less than 0·008 per cent. In sheep's spleen the calcium was reduced from 0·09 to 0·03 per cent and iron from 0·15 to 0·05 per cent, but the percentage of copper was slightly higher in the residue than in the dried spleen.

Further analysis by the flame method proves that precipitate (1) contains most of the copper, silver and some lead, (2) iron phosphate, (3) zinc and cadmium sulphides and (4) manganese, nickel, cobalt, cæsium (sometimes present) and some rubidium as ferrocyanides. Healthy liver contains much more zinc than appears to be realized; nickel was easily detected in it, but of cobalt there has only been the slightest evidence of its strongest line. The spleen and heart also contain zinc and minute traces of nickel, and traces of cadmium were found in one sheep's liver and in a salmon's liver which also contained zinc and nickel. Arc or spark spectra of these precipitates would probably reveal the presence of other trace metals. The 'ashing' of tissues is often a very slow process, and some metals such as zinc, cadmium and the alkalis volatilize in varying degrees. These results are given tentatively as indications of the merits of the method and of the uses to which it may be applied.

Sheep diseases are very serious matters also in parts of Great Britain and are under investigation. Mr. J. B. E. Patterson, of Dartington Hall, Devon, recently sent me samples of the livers of four sheep which had died from one of these diseases, and evidence of changes in the mineral content as compared with normal livers has been obtained. There are indications too of a faulty metabolism resulting in the accumulation of oil, or compounds containing oil, in the liver to such an extent as to affect its normal working.

Many questions present themselves: for example, (1) effects of age on the composition of extract and residue; (2) changes caused by diseases, such as cancer; (3) changes due to imperfect feeding; (4) the effects of 'drugs', etc.; but the facilities at my command—a (spectroscopic) laboratory 14 ft. × 7 ft., furnished only with gas service—will not enable me to go far in answering them. This letter will serve, perhaps, to attract attention to what I believe to be a new and useful line of attack.

Relation of so-called *Streptococcus apis* to certain Lactic Acid Streptococci

ONE of us has previously reported the isolation, from larvæ affected with European foul brood, of strains of *Str. apis* identical in every respect except that of gelatinolysis and caseolysis[1]. It has now been found that these two *Str. apis* strains are indistinguishable morphologically, culturally and biochemically from the well-recognized dairy types *Str. glycerinaceus* and *Str. liquefaciens*, the former being a non-proteolytic variant of the latter[2,3]. Thus all four types occur as diplococci and occasionally as short chains. They grow well in litmus milk at 15° and at 45° (the proteolytic *Str. apis* causing a breakdown of the casein similar to that produced by *Str. liquefaciens*); ferment glucose, fructose, lactose, galactose, maltose, mannose, sucrose and salacin strongly; glycerol, dextrin and trehalose slightly; but not arabinose, inulin, starch, xylose, inositol, adonitol or erythritol. Sorbitol and mannitol are usually, and raffinose not usually, fermented. Aesculin is fermented to give a positive reaction with ferric chloride. In glucose broth a final pH of 4·1–4·2 is obtained. All four types also grow in bile salt lactose broth, and resist heating at 60° for 15 minutes in milk at pH 6·6.

The question of nomenclature and the relation of these types to other streptococci will be dealt with later.

A New Microcolorimetric Apparatus and a Method for Determination of Total Blood Volume

IT is a matter of importance in physiology to construct an apparatus by which it is possible to determine the concentration of very weak dye-solutions in small quantities, without any decrease in its layer-thickness. In my apparatus a capillary tube is used with a volume of 10 cubic millimetres and a length of 20 millimetres. In this capillary tube is placed the dye-solution, the concentration of which is to be determined. The tube is covered with a black paper-hull to keep out the light from the side. The tube is hung vertically by a holder of simple construction on the object stage. This dye-solution is enlarged by the microscope, from which the eyepiece has been removed. In its place there is a prism-system, which is similar to the upper part of a Duboscq colorimeter. The prism cuts off the rays in one half of the field of vision. Under the other half of this prism is fastened a wedge in order to compare the concentrations of the dye solutions. This wedge can be moved horizontally by a screw in front of a scale. Under the wedge is a light-filter, a diaphragm and an illuminating mirror from which the rays are directed through the filter, diaphragm and wedge to the other half of the eyepiece; the scale is determined by the aid of dye solutions of defined concentration. The unknown dye solution is put into the capillary tube. The wedge is screwed until there is an equalization of colour intensity and so the concentration of dye solution can be easily calculated. In this way one can estimate the colour concentration of dye solution between 1 : 10,000–1 : 100,000. It can be used also for determination of weaker and stronger dye solutions by changing the length of the capillary tube.

This method was used for the estimation of the total blood volume of white rats. For the determination, Congo Red was used. The blood volume of forty normal white rats of the same breed was estimated. 25–50 cubic mm. of blood is necessary for the estimation. The process is similar to Went and Drinker's method, but in the colorimetry there is an essential difference. As a result of this investigation it was found that the total blood volume per 100 gm. body weight is 4·19 ± 0·6 cubic centimetre on the average. Other control experiments are in progress.

University, Budapest.

Mock Suns observed at Nanda Devi in Garhwal

DURING the recent British American Himalayan Expedition, from an altitude of about 21,000 ft. on Nanda Devi in Garhwal, we saw at 3.30 p.m. on August 20 a particularly fine display of parhelia, or 'mock suns'. The two lateral images and the lower one were especially bright, and were arranged as usual on a broad halo of light. The weather was cold at the time, unusually so even at that altitude for the monsoon period, 20° F. being recorded on the mountainside that same evening. We had on several previous occasions seen solar haloes, as we approached Nanda Devi via the Rishiganga gorge, but no certain appearance of 'mock suns', and the weather following the occurrence of these haloes had been fair and not particularly cold.

The afternoon of August 20, however, preceded by about thirty hours the worst blizzard we experienced during the course of the expedition. This blizzard, accompanied by a violent wind from the east—a southerly monsoon wind, we believe, deflected off the neighbouring great south face of Nanda Devi—held us in our tents at 21,300 ft. (Camp III) for about thirty hours, the minimum temperature on this occasion being recorded at 12° F.

I am well acquainted with the phenomenon of 'mock suns' in the Arctic, but I am unaware that it has been recorded previously from such low latitudes as those of the Himalaya, in this instance lat. 30° 22′. Its occurrence during the monsoon period, and at the altitude observed, would appear to indicate exceptionally low temperatures in the upper atmosphere. But 1936 will long be remembered in India for its unusually intense and prolonged monsoon.

It may also be of interest to record that on August 29, from the summit of Nanda Devi (25,645 ft.), Mr. H. W. Tilman and I looked through a still and clear atmosphere (the air temperature was 19° F. at 3 p.m.) towards the great 70-mile circuit of mountains of the rim of the Nanda Devi basin. The latter, as well as features beyond, were partially obscured by rising columns of cumulus cloud of very beautiful form. We learnt later that, while we were bathed in sunshine throughout the day, the districts to the south and west beyond the "rim" were experiencing disastrous floods, Mussoorie receiving as much as 19 inches of rain in the course of that day.

Points from Foregoing Letters

USING a hydrogen bond as the mechanism whereby 'laminar' protein molecules are formed from closed polypeptides, Dr. D. M. Wrinch and Dr. D. Jordan Lloyd elaborate possible structural formulæ and deduces that individual protein films must possess characteristic permeabilities and densities.

The optical rotation of lactic acid obtained from l-α-bromopropionic acid may be either left-handed like that of the parent compound, or may show inversion to right-handed rotation; this depends on whether the conditions are such as to favour a uni- or bimolecular reaction, as shown by the rate at which the change takes place. W. A. Cowdrey, Dr. E. D. Hughes and Prof. C. K. Ingold mention this as a particular instance of the general importance of paying attention to the rate of reaction in connexion with the Walden inversion.

From an investigation of the pedigree of four more families in which both colour blindness and hæmophilia occur, Dr. Julia Bell and Prof. J. B. S. Haldane conclude that these conditions, which are sex-linked, are also linked (and therefore transmitted) together. In the six pedigrees studied there was only one case of crossing-over, a colour-blind hæmophilic having a colour-blind non-hæmophilic brother.

The cause of the distortion associated with the remarkable yield in iron and soft steel is discussed by Dr. E. W. Fell. He considers it probably due to the mode of distortion of single iron crystals (multiplicity of slip-planes) and to small crystal size. This facilitates *transmission* of the distortion throughout the aggregate of crystals. Attempts to confirm this by producing similar effects in β-brass and molybdenum are described.

By means of a device making use of simultaneous modulation of a valve transmitter and a valve receiver, H. Antoun and F. Minaw have succeeded in carrying out simultaneous transmission and reception of radio waves. They submit a photograph showing a special wave form of modulation and another showing patterns of transmitted groups of waves.

How a double star may act as an enormous 'cyclotron' and accelerate charged particles moving in the electric field derived from a difference of potential between the stars or from their rotation, is described by Prof. H. Alfvén, who calculates that the particles can in this way obtain energies such as are found in cosmic rays.

Following upon Rogers's suggestion that the red blood corpuscles of echidna might prove to be nucleated, Prof. E. A. Briggs has examined a series of blood smears from the primitive Prototheria, platypus and echidna. The erythrocytes are typically mammalian in form, being non-nucleated biconcave disks.

In view of the importance of small amounts of certain metals for the health of animals, H. Ramage describes a method of extraction of the 'soluble' mineral constituents by means of dilute hydrochloric acid, and gives the percentage of calcium and iron found by this method in the liver and spleen of sheep.

An experimental arrangement for determining the concentration of weak coloured solutions in small amounts of the liquid (one drop or less) is described by Dr. J. Ch. Somogyi. The method has been used in estimating the total blood volume of white rats.

Research Items

Boat Construction in Ancient Scandinavia and Oceania

MR. JAMES HORNELL, following up previous studies of similarities in the methods of boat construction in ancient Scandinavia and Oceania, directs attention in *Man* of September to the character of a boat from Botel Tobago, a small island off the coast of Formosa, now in the Hamburg Museum of Ethnology. This bears out a statement made in general terms by J. W. Davidson that the Botel Tobago boats were almost an exact counterpart of the boats constructed in the Solomon Islands as to form, method of construction and ornamentation. They are, in fact, of the Solomon Island *mon* type, and with the Moluccan *orembai* belong to the same class of naval design. The greater crudity of the *mon* and the *orembai* is probably due to degradation. The boat is equal ended, each end being sharp and rising in a gracefully abrupt fashion, and terminating in an acuminate point. The greatest beam is amidship, and the gunwale assumes a broadly lanceolate shape. The base of the hull consists of a narrow salient keel spliced to a narrow curved stern post. On each side of the keel are three wide strakes. The two lower run horizontally, and are shorter than the third, of which the terminal sections form the up-curved end-pieces. Each half end-piece is cut from the solid. The planks are held together initially by means of wooden dowel pins inserted into opposed edges. The dowel attachment is reinforced by lashings. Three sets of cleats, shaped out in the planking, give attachments for a transverse frame, a triangular bulkhead board, and the tie of the converging sides at each end. Probably there were paddling thwarts, though none is now present. The method of lashing the hull planking is more nearly related to that of the Scandinavian type than in either the *mon* or the *orembai*; and the presence of keel and stem posts is another approximation to the later Viking boats, which is not present in the round-bottomed *orembai* and *mon*. The striking resemblances to the Scandinavian boats raises interesting questions as to distribution and diffusion of design.

Yavapai Indians

A FURTHER study of Yuman peoples has been added to the series which is now nearing completion in Mr. E. W. Gifford's investigation of the culture of the north-eastern and western Yavapai (*Univ. California Pub. Amer. Archæol. and Ethnol*, 34, 4). The Yavapai were unique among the Yuman groups in inhabiting a vast territory, embracing some 20,000 square miles and roughly 200 miles in east-west dimensions and 100 miles in north-south dimensions. This country afforded a wide variety of territory, ranging from the low country of the confluence of the Gila and Colorado Rivers to the high ground of central Arizona; and therefore affords an exceptional opportunity for studying the adaptability of a hunting and gathering people to various environments. These adaptations must have been made within a few centuries, as the country is dotted with the settlements of an earlier Puebloid population. Evidently they adopted little of the cultural habits of their agricultural predecessors. They were nomadic; and their country was sparsely occupied, each group wandering over its territory in search of the ripening plants and the animals on which it subsisted. This is indicated by the table of seasonal occupations given by one of the informants. The Yavapai have much in common linguistically and culturally with their northern neighbours, possibly owing to a not very distant origin from a common stock, as they themselves assert. The Western Yavapai appear to have absorbed certain elements of Yuma-Mohave culture and rejected others. The Navaho traded with the North-eastern Yavapai, bringing woven blankets, shell-beads and turquoise on donkeys. Occasionally the Yavapai visited the Navaho country with buckskin, mountain lion skins, and mescal, sometimes speaking Navaho themselves, sometimes using Tonto Apache as interpreters. The Yavapai afford an unusual opportunity for appraising the influence of two environments, one geographical and one social.

Prehistoric Relics in Malta

A STRIKING feature of the annual report of the Museum Department of Malta for 1935–36 is the number of discoveries of prehistoric relics of human beings and animals made on the island. Twelve rock-tomb burials were accidentally met with, and are described briefly, and prehistoric cave-dwellings and a neolithic site (at Kalet Marku) were excavated. The remains of prehistoric animals are equally interesting and impressive: elephants, tortoises, a frog or toad, extinct birds, and a new species of otter and others from one Pleistocene fissure, and from another, *Elephas falconeri*, *E. melitensis* and *Hippopotamus pentlandi*. These represent only a small part of the remains discovered and described during the year.

Food Production and Nutrition

"STATISTICS of Food Production, Consumption and Prices" is the title of the fourth volume dealing with food and nutrition issued by the League of Nations (The Problem of Nutrition, vol. 4. London: Allen and Unwin. 3*s*.). It is a preliminary study by the International Institute of Agriculture, Rome, of the available statistical material on the production, consumption and prices of the chief protective and other foodstuffs, for example, milk and dairy products, meat, eggs and poultry, fruit and vegetables, cereals and sugar. Half the volume is devoted to an analytical examination of the situation in the limited number of countries for which data exist. The remainder of the volume gives statistical tables relating to production and consumption, with wholesale and retail price indexes. The financial assistance rendered to agriculture in some of the principal agricultural countries is also dealt with. The information collected illustrates the incompleteness of the data available in respect of most of the foodstuffs considered.

Geckos of Japan

THE first of a series of papers to be published upon the lizards of Japan deals with the geckos (Yaichiro Okada, *Sci. Rep. Tokyo Bunrika Daigaku*, 2, 233; 1936). Fourteen species are here recorded, described and illustrated. They belong to seven genera, all found in tropical and subtropical regions. But of the fourteen species, only seven are regarded as endemic, the remainder having a wide distribution embracing South China, the Malay Peninsula, and the Philippines. Such distribution is easily accounted for by the ease with which the species, attached to vegetation or some object, are transported by Nature or by man. Yet in spite of the possibilities none has succeeded in establishing itself in the Arctic region.

Environment of Marquesan Insects

THE insect fauna of the Marquesas Islands has been extensively investigated under the auspices of the Pacific Entomological Survey, the central organization of which is at Honolulu. In Bulletin 139 (1936) of the Bernice P. Bishop Museum (forming Pacific Entomological Survey, Publication 9), Mr. A. M. Adamson gives an interesting account of the topography, geology, flora, etc., of the islands, which serves as a background, or basis, for the discussion of their faunistic relations. The islands are the most remote from a 'continental' region of any archipelago in the world, the coast of Mexico being nearly 3,000 miles away and Fiji about 2,700 miles. Their total area is only about 400 square miles; their general altitude is but little more than 4,000 ft. and the coasts are almost entirely unprotected by coral reefs. The greater part of the endemic fauna is now restricted to the higher altitudes, where the climate is very moist and the temperature temperate, rather than tropical. The specific endemism of the flora is much lower than that of Hawaii, with which it has affinities: on the whole, the flora is most nearly related to that of the Society Islands. Three vertical zones of plant distribution can be distinguished, the uppermost, or rain forest, containing the chief food plants of the indigenous insects. The native flora below 1,000 ft. has been replaced in large measure by immigrants and to a certain extent up to 2,500 ft. also. It is evident that the changes being brought out by colonization, either directly or indirectly, are already very marked, and the present survey is a timely one. Probably many species of insects have been already lost, and many more will disappear in the not-distant future.

Hormones and Horticulture

A USEFUL résumé of present-day knowledge of plant hormones, or growth-regulating substances, is given by Dr. M. A. H. Tincker (*J. Roy. Hort. Soc.*, 61, Pt. 9; Sept. 1936). The history of investigation in this subject goes back to Darwin, and the work of Rothert and Fitting, of Boysen-Jensen, and later of Loeb and Went, established the idea of chemical 'messengers' or regulators, as a feature of plant physiology. Much of the earlier work dealt with the bending of coleoptiles of cereal seedlings, but the findings of Went, that a root-forming substance was produced by leaves, initiated a new line of horticultural inquiry. Later investigations showed that the growth-promoting substance was an organic acid. It was produced by a wide variety of plants, and was even found in such products as rice polishings, wheat-germ oil and pollen. The active substance is β-indolylacetic acid, and it can be synthesized *in vitro*. Perhaps the most valuable line of future horticultural work is that suggested by Hitchcock and Zimmerman, who have used root-producing hormones in the propagation of difficult cuttings such as maple and apple.

A New Disease of Stocks

A PAPER by Mr. W. M. Ware (*Gard. Chron.*, Sept. 26, 1936) announces the appearance of a new disease of cultivated Stock plants (*Matthiola* spp.). It is caused by a fungus belonging to the genus *Alternaria*, but its exact specific relations have not yet been determined. The fungus can flourish when conditions are good for the growth of Stocks, and it appeared first in a greenhouse where a crop was being raised through the winter. Extensive spots, either somewhat dry, or bearing a copious fructification of spores, appear on the lower leaves of hybrid strains, the Ten Weeks Stocks being apparently immune or highly resistant. Control by removal of diseased leaves proved laborious and only partly effective, whilst fructifications actually appear amongst sulphur dust. The problem of eradication is still further complicated, for it is imperative that the fungus be controlled in its early stages, before the leaves which must be included with the marketable bloom are infected.

A Catalogue of Earthquake Epicentres

IN the University Observatory at Oxford, two card catalogues of epicentres are kept, one arranged in order of latitude, the other in that of longitude, with the dates on which the corresponding foci have been in action since the year 1913. Both catalogues are in constant use at the Observatory, and Miss Ethel F. Bellamy has done good service to seismology by reproducing the former in her "Index Catalogue of Epicentres for 1913–1930" (Isle of Wight: County Press, Newport, 40 pp.; 1936). Miss Bellamy's "Catalogue of Earthquakes 1925–1930", an abbreviation of the "International Seismological Summary", was published a year ago, and all who have worked with it must have appreciated its accuracy. Her new work, which must have been equally laborious, she regards as a geographical index to the Summary. It is divided into four parts. In the first, the epicentres in north latitude and east longitude are arranged in increasing order of latitude, and, when several epicentres lie on the same parallel, in increasing order of longitude. The other parts are similarly arranged for the remaining quadrants. The dates on which earthquakes have occurred beneath each epicentre are entered according to the year, month and day, those in which earthquakes possessed deep foci being printed in italics. The positions of the epicentres are plotted on an equal area projection map of the world, a map that shows very clearly the concentration of activity in the Mediterranean area, the East Indian Archipelago and the margins of the Pacific Ocean. A similar map represents the distribution of seismological stations throughout the world, their clustering in Europe and Japan and their sparseness in Africa, Central Asia and the East Indies and neighbouring islands. This distribution may be in part responsible for the much greater number of earthquakes recorded in the north-east quadrant and in the zone between the parallels of 35° and 45° of north latitude.

Railway Signals for Fogs

IN the October issue of the *Journal of Scientific Instruments*, Mr. A. E. Tattersall describes two forms of signal lamps which, while not so effective as those he described in the same journal a year ago, require less power and will do something towards securing greater safety in running during fogs. Both are operated by wires from the signal box placing the necessary coloured glasses before the lamp, which is about 11 ft. above the rails. Both secure a parallel beam of light by reflecting the light of an electic lamp with a concentrated source of 5–10 watts at a spherical mirror the spherical aberration of which is compensated by a glass lining. Any special form of distribution of the issuing light beam is secured by the form of the glass front of the box in which the lamp is housed.

X-Ray Method for determining Electronic Charge

THE absolute wave-length of X-rays is now known from ruled grating measurements with a high degree of accuracy. A precise determination of the angle of diffraction from a crystal leads to a value for the crystal spacing, and by using the crystal density, to a value for the absolute atomic masses and for the electronic charge. A new measurement by J. W. M. Du Mond and V. L. Bollman (*Phys. Rev.*, 50, 524) overcomes the objection which has been made to this method that the density is determined for a large crystal while the X-ray reflection involves only the surface layers. The crystals used in the work were very finely powdered calcite in which the depth of penetration of the rays embraces the whole fragment. The density was determined on the same powder specimen. The value obtained for e was $4{\cdot}799 \pm 0{\cdot}007$ E.S.U.

Excitation of Nuclei by Proton Bombardment

L. R. HAFSTAD, N. P. Heydenburg and M. A. Tuve (*Phys. Rev.*, 50, 504) have been able to study in detail the yield of alpha- and gamma-rays from fluorine and lithium as a function of the energy of the bombarding protons. The tube and the Van de Graaff type generator are improved versions of those used in former experiments, and the voltage was measured by a galvanometer and high resistance. The alpha-particle emission from lithium had to be studied with a thick lithium target, and unambiguous results on the excitation function were not obtained. In the gamma-ray excitation of lithium, a resonance-voltage at 440 kv. was observed, and the half-width of this resonance was estimated as 11 kv. In the excitation of fluorine, resonance levels were found at 328 kv., 892 kv. and 942 kv., with half-widths of 4, 10, 15 kv. respectively. The width of the lithium excitation region is probably connected with the time of relaxation of an excited level in ^{8}Be, and a discussion of the probable mechanism of this relaxation is given.

Phosphatase of Cows' Milk

THERE is already strong evidence that the phosphatase of cows' milk arises directly from the secretory cells of the mammary gland. This is confirmed by S. J. Folley and H. D. Kay (*Enzymologia*, 1, 48 ; 1936) as the result of the study of the phosphomono-esterase content of the milk of sixty-six Dairy Shorthorn cows in relation to the progress of lactation. They find that the advance of lactation is accompanied by regular changes in the concentration of the phosphomonoesterase, the output of the enzyme in the milk rising to a maximum at about 180 days post-partum, whereas no such regular changes in enzyme content occur in the blood serum as lactation progresses. The results suggest that the rate of secretion, or it may be unavoidable loss of phosphatase in the milk, is in general inversely related to the functional efficiency of the mammary gland. It is therefore considered highly probable that the enzyme comes from and is continually being synthesized by the secreting cells of this gland.

Absolute Activity of Choline Esterase

THE enzyme choline esterase arouses interest not only because of its function in the body of destroying the acetylcholine by means of which so many nerves produce their effect; it is reversibly and specifically poisoned by a group of synthetic urethanes allied to eserine. L. H. Easson and E. Stedman (*Proc. Roy. Soc.*, B, 121, 142 ; 1936) have reached various interesting conclusions as the result of a quantitative study of the activity of this enzyme under different conditions. They assume that the substances which inhibit the enzyme act by combining with it in the same way as the choline esters, and thus blocking the active groups. They assume that the combination between enzyme and inhibitor is governed by the laws of mass action. The experimental data agree well with these assumptions. The authors have thus calculated the number of active groups in their enzyme preparations and have come to the conclusion that each active group hydrolyses about 3,500 molecules of butyryl choline per second, or 1,490 molecules of acetylcholine. This conclusion may be compared with various calculations of the rate of working of each molecule of an enzyme. The new method of reasoning gives results that refer to active groups rather than molecules, but they are of the same order of magnitude as those obtained for molecules of invertase. Some enzymes work more quickly than this, others work more slowly. The calculations are complicated by the fact that the inhibitor substances are themselves slowly destroyed by the enzyme.

A Catalogue of Stellar Proper Motions

A KNOWLEDGE of stellar proper motions—the small progressive angular changes of the relative positions of stars—is of basic importance to astronomy. In the first place, proper motions provide data for the study of the spatial movement of individual stars, for 'star-streaming', and for the motion of the solar system ; secondly, they enter into any work involving the reduction of measures for star places on photographic plates, such as astrographic chart work and the determination of the parallaxes of stars. Proper motions may be derived from a comparison, after a sufficient lapse of time, of the positions of stars as given in various catalogues, based on meridian observations, or from photographs taken with a fairly long time-interval (say, thirty years) between them. In 1923, Dr. Richard Schorr, director of the Hamburg Observatory at Bergedorf, published a catalogue of proper motions including more than 21,000 stars, compiled from various sources. He has now published a new edition of this work (*Bergedorfer Eigenbewegungs-Lexikon*, 1 and 2) in which all proper motions available up to the end of the year 1935 are collected together from every available source. The new catalogue, which is conveniently arranged for reference in one degree zones of declination, contains no fewer than 94,731 stars, of which 60,642 are in the northern hemisphere. These tabulations, together with footnote references to the large number of proper motions published in the *Greenwich Astrographic Catalogue* (4, 5 and 6) and in the five catalogues by Schlesinger (*Yale Transactions*, 4, 5, 7, 9 and 10) provide a complete means of ascertaining in a few minutes whether a star has any measurable proper motion. The value of such a catalogue is obvious, and Dr. Schorr will deserve the thanks of astronomers for the compilation of this extensive work.

International Commission on Large Dams

CONGRESS AT WASHINGTON

THE Second Congress of the International Commission on Large Dams was held in Washington, D.C., on September 7–12, concurrently with the meetings of the World Power Conference. The joint opening session of the Conference and Congress was held on September 7 in the Constitution Hall and a joint closing session on September 12 in the Government Auditorium. A further joint meeting was also held on September 11 when President Roosevelt addressed the delegates and welcomed the numerous visitors from abroad.

Apart from the joint sessions, the meetings of the Dams Congress were confined to the discussion of a limited number of technical questions. These questions, five in number, had been selected well in advance of the Congress, and more than sixty papers were presented for discussion. In addition, there had been appointed for each question a general reporter whose duty it had been to prepare a general report summarizing the various papers on each topic. Advance copies of most of the papers were available before the meeting, and were accompanied by summaries in English, French, German and Spanish. The five questions selected for discussion were special cements, design and waterproofing of shrinkage contraction and expansion joints, the facing of masonry and concrete dams, geotechnical studies of foundation materials, and the calculation of the stability of earth dams. Some twenty communications on miscellaneous topics were also presented, but were not discussed at the meetings.

The importance of the use of special cements for concrete dams and other large concrete structures, to which attention was directed at the first Congress held in Stockholm in 1933, was evidenced by the numerous papers from many countries which this subject attracted. Subsequent to the Stockholm Congress, an International Sub-Committee on Special Cements was set up by the International Commission on Large Dams, and national committees were also formed in many countries in collaboration with it.

The object of the work of the International Sub-Committee was to examine, and, so far as possible, obtain agreement, on methods for testing those properties of cements which assume special importance in large mass concrete structures; and to stimulate the interest of cement manufacturers in the production of cements specially suited for such types of construction. The properties demanded of such cements are: as low a heat of hydration as possible in order to reduce the temperatures attained in the concrete mass, a rather long setting time so as to enable large volumes of concrete to be placed without undue stiffening, good workability to facilitate placing without segregation or separation of water from the mixed concrete, a high ultimate concrete strength but only relatively low strengths at early ages, good resistance to the solvent action of percolating water, and no abnormal drying shrinkage. The necessity in modern dam construction for paying special attention to the properties of the cement used has its origin in the much increased rate at which large concrete dams are now built.

Two papers of particular importance were the interim report of the International Sub-Committee on Special Cements and the report from the U.S. Bureau of Reclamation. The former report, which was the result of experimental work carried out in a number of different countries, including Great Britain, tentatively recommended test methods for measuring the heat of hydration and solubility of cements; it also contained a description of the method used in Germany for comparing the drying shrinkage of cements and reports by Swedish investigators on the workability of concrete. The report from the U.S. Bureau of Reclamation prepared by Mr. J. L. Savage, chief designing engineer, was a document of more than two hundred pages containing a very valuable summary of investigations made in the United States on special cements, and of the experience gained with them in the construction of a number of large dams, including Boulder Dam on the Colorado River, Bonneville and Grand Coulee Dams on the Columbia River and Norris Dam in the Tennessee Valley.

In discussing the design and waterproofing of joints in mass concrete, a distinction was drawn between shrinkage joints, the function of which is limited to the construction period and to the earlier part of the operating period, and contraction and expansion joints which are intended to guard against movements occurring over the entire life of the dam. The general consensus of opinion was that contraction joints at intervals of 12–15 metres should be provided in all concrete gravity dams, but with respect to arch dams no general agreement as to their necessity or otherwise was reached. The various methods for sealing joints by the use of metal plates, of bitumen, rubber, and cement grouting were discussed in detail in several of the papers presented. The use of copper or stainless steel joints was preferred.

The reports submitted on the subject of facings for masonry and concrete dams dealt with the different methods which have been developed for reducing or preventing water percolation through the upstream face, and, when climatic conditions are severe, for protecting the face against damage by frost and by abrasion from floating ice and debris. The relative merits of masonry, cement mortar and rich concrete facings formed a controversial subject, some authors holding that under severe frost conditions not even a rich concrete can be expected to stand without damage, if it is exposed in a wet state, and that protection, as by a masonry facing, is necessary. Other contributors were not, however, in favour of masonry facing on account of the risk of the opening of joints owing to differences in thermal expansion between the face and the concrete behind. The use of metallic coverings or diaphragms, and of bituminous coatings suitably protected to obtain an impervious face, was also discussed. At a subsequent meeting of the Executive Committee of the International Commission on Large Dams, a resolution was passed that when suitable precautions are taken to obtain a resistant concrete face, no other protection is necessary.

Under the topic of geotechnical studies of foundation materials, most contributors dealt with the geological investigation of dam sites and the treatment of unfavourable conditions by grouting with cement, bitumen, clay and chemical consolidation processes. The discussion mainly centred round the best methods of sampling and coring in investigations of the foundations for proposed structures.

The discussion on the stability of earth dams was largely concerned with problems of design, foundations, construction, and resistance to earthquake shocks, and the stability of the slopes of dams.

Both before and after the Conference and Congress in Washington a series of study tours was organized to permit visitors to inspect hydro-electric power plants in the United States and Canada, and to visit some of the large dams recently constructed or now under construction. The visit to the Tennessee Valley authority was also of more than technical interest since it afforded an opportunity for the study of the application of hydro-electric power development in regional planning.

The longest tour, which attracted some two hundred visitors from abroad, including more than twenty from Great Britain, was concerned with major constructional projects, largely in the field of dam construction and hydro-electric power development. Visitors on this tour were privileged first to visit Canada for the inspection of plants near Montreal and Ottawa and then to proceed to Niagara, Chicago and the west coast of the United States. Visits to the Fort Peck Dam on the upper reaches of the Missouri River in Northern Montana—to the Columbia and Skagit River developments in the State of Washington, to power development schemes in California, and to Boulder Dam, as well as to various laboratories in which research work bearing on problems of dam construction was being carried out, all combined to make a memorable tour.

Throughout the meetings at Washington and the subsequent tours in the United States, visitors were afforded widespread hospitality and help from their American hosts, to whom all owe a deep debt of gratitude. Special mention should also be made of the hospitality shown in Ottawa, Montreal and Niagara by the Canadian Government, and the provincial Governments of Quebec and Ontario.

F. M. Lea.

International Congress of Experimental Cytology

Meeting at Copenhagen

The fourth International Congress of Experimental Cytology was held in Copenhagen on August 10–15 under the presidency of Prof. T. Huzella, the office of local president being filled by Dr. Albert Fischer.

The opening meeting of the Congress took place in the Reception Hall of the Parliament, Christiansborg Castle, where the members were welcomed by the local president and by the rector of the University of Copenhagen, after which two short lectures were given, one by Dr. Alexis Carrel on "La Cytologie Nouvelle" and the other by Dr. August Krogh on "Modern Biology".

The ordinary sessions were held in the Physiological Institute, a modern and beautifully equipped building which was admirably adapted for the purpose. The proceedings of the Congress were not divided into concurrent sections, so that it was possible for a sufficiently robust member to attend all the papers if he so wished. The enormous variety in the subject-matter of the papers presented permitted of only the loosest classification in the programme, and, in this short account, it is impossible to mention more than a few of the communications, selected almost at random, to give some idea of the field of work covered by the Congress.

Two sessions were devoted to the physical chemistry of the cell. Dr. Edmund Mayer described a method for measuring the physical forces acting on growing cells in a semi-solid culture medium by placing small metal balls in the medium and measuring the magnetic force required to displace them. Prof. T. Peterfi described experiments in which the volume of an amœba was measured at different stages in its life-cycle, by sucking the organism into a cylindrical micro-pipette.

One session dealt with histo-chemistry. Miss C. F. Fischmann gave an account of her work on the influence of vitamin D on ossification *in vitro*. Drs. P. Lamarque and J. Turchini described a new technique of historadiography whereby X-ray photographs of histological preparations can be made and examined microscopically.

During the session on cell respiration and metabolism, Dr. K. Linderstrøm-Lang gave an account of his work on the distribution of proteolytic enzymes in the different portions of the glands of the stomach, and in certain other tissues, notably in growing root-tips. Dr. Albert Fischer described experiments on blood coagulation and the mechanism of cell nutrition. Messrs. F. Jacoby, O. A. Trowell and E. N. Willmer read a paper in which they showed, by photographs taken automatically at 6-minute intervals, that embryo tissue juice not only accelerates the migratory movement of tissue culture cells and increases the percentage of dividing cells but also shortens the duration of mitosis.

Papers on the experimental morphology of the cell occupied four sessions. Prof. W. von Möllendorf, in a communication illustrated by a fine film, described how the duration of various phases of mitosis can be altered under the influence of different ions. Dr. C. Robinow discussed the problem of cell boundaries and showed with the aid of lantern slides of singularly beautiful photomicrographs, that the boundaries are much more irregular and complicated than the ordinary impregnation methods indicate. Prof. T. Huzella described the effect of different vibrations on tissue growth *in vitro*. Dr. J. Hämmerling gave a paper on the influence of the nucleus on the development of the unicellular plant *Acetabularia*; he showed that if the proximal nuclear region of one species were cut off and grafted on to the non-nuclear region of another species, the non-nuclear region assumed the specific characters of the nucleated graft, indicating that the specific characters are controlled by the nucleus. Dr. A. F. W. Hughes gave a communication on the influence of the circulation upon the vessels of the area vasculosa of the chicken's egg.

The last two sessions were devoted respectively to the experimental pathology of the cell and to the biological effect of radiation.

A large number of demonstrations were exhibited. Dr. Alexis Carrel and Colonel Lindbergh personally demonstrated their perfusion apparatus in operation. Of special interest were a number of lantern slides showing photomicrographs of histological sections of organs grown in the apparatus for different periods. Similar slides of control organs were shown for purposes of comparison, and there was surprisingly little histological difference between the normal and explanted tissue.

The Congress was marked by the large number and high average standard of the cinema films exhibited. Many of the films were projected immediately after the communications which they illustrated, but the rest were shown on a special evening set apart for the purpose. An enthusiastic reception was given to the last films of the late Dr. Canti, made in conjunction with and demonstrated by Dr. John Bland, in which tissue cultures of gliomata and of cells infected by psittacosis virus are shown.

The local committee deserves congratulation for its highly efficient organization, and the members of the Congress must have carried away with them delightful memories of the lavish hospitality with which they were entertained throughout their visit and of the surpassing excellence of Danish cookery.

Physical Properties of Heather Honey

EVER since Major Hruschka, in Venice, discovered in 1865 the principle of honey extraction by the application of centrifugal force, in a rotary extractor, it became no longer necessary to destroy valuable combs in order to separate the honey from the wax. All the native honeys in Great Britain yield to this method of treatment, excepting that derived from the nectar of ling (*Calluna vulgaris*). Ling honey fails to flow from the combs in an ordinary extractor, and consequently the combs have to be crushed in a press to obtain extraction. Ling honey is rich golden brown in colour and shows a characteristic sparkle due to the presence of minute air bubbles. In the pure form it never granulates but remains as a gelatinous fluid which is more viscous than most other honeys. Its distinctive flavour and aroma also readily distinguish it from other honeys.

In the *Bee World* for August 1936, Mr. J. Pryce-Jones discusses certain of the physical properties of ling honey. Mr. Pryce-Jones has examined more than 250 samples of honeys from various parts of the world: 73 of these were ling honey in varying degrees of purity and 27 were samples of bell heather honey. All the samples of ling honey were thixotropic, but none of the bell heather samples, when free from ling honey, showed this feature. The degree of thixotropy in a sample of ling honey is closely related to its purity. Also the absence of thixotropy in a sample of honey may be taken as an indication that it contains less than 5 per cent of ling honey. The property of thixotropy may be illustrated by taking a small amount of finely divided clay and shaking it with five times its weight of water containing traces of common salt. If such a mixture be shaken in a narrow test tube it flows freely when the tube is inverted, but if it be left at rest after shaking it sets into a jelly. If the tube be shaken again the mixture flows once more but sets anew on standing. This property, which is one of certain colloids, is termed thixotropy.

Ling honey also shows another peculiar and related feature which Mr. Pryce-Jones terms elastic recoil, and he describes the apparatus used in its investigation. These two properties seem to be due to the amount of colloidal material present in ling honey. Appreciable amounts of colloids can be precipitated by suitable reagents. Thixotropy and elastic recoil are eliminated by the removal of this precipitate, while the addition of the ling colloids to other honeys imparts to them these same two properties, which they did not previously exhibit. Certain other honeys, from Australia and New Zealand, also exhibit thixotropy but, so far as the author is aware, ling honey is unique in its physical properties among the honeys of Great Britain.

In the *Journal of the Ministry of Agriculture and Fisheries*, October 1936, Dr. G. W. Scott Blair and Mr. D. Morland contribute an article on practical tests for ling honey. They refer to the closely connected properties of structural viscosity and thixotropy in honeys of this kind. There is reason to believe that the sugar molecules tend to arrange themselves into a sort of structure like scaffolding around a building. When honey is stirred, or caused to flow, this structure is broken up and only becomes reformed gradually. A method devised by Scott Blair (*J. Phys. Chem.*, 39, 1935) is a convenient test for evidence of such a structure. A ¼-in. steel ball-bearing is dropped through a sample of honey, which has been allowed to stand overnight, contained in a 100 c.c. Nessler tube. The tube is marked with two lines about 2½ in. apart and the times at which the centre of the ball passes these two lines is noted. The honey is then stirred by a metal disk perforated with holes and mounted on a rod so that it just slides freely in the cylinder. The disk is pushed to the bottom of the cylinder and withdrawn twice; immediately after this a ball-bearing is dropped and the times noted as before. The 'thixotropy ratio' is obtained by dividing the time taken by a ball to fall between the two lines in the first test by that taken by the other ball in the second test. This simple method is well adapted for the judging of honey samples, since it allows of physical properties to be tested in a way capable of repetition, and so eliminating most of the personal factor that has hitherto prevailed.

New Laboratories of the Mond Nickel Co., Ltd.

At a reception which preceded the inspection on October 21 of the new Research and Development Department Laboratory erected by the Mond Nickel Co., Ltd., in Wiggin Street, Birmingham, Lord Weir referred to the great extension that has taken place in the use of nickel and its alloys during the last decade. Before 1914, most of the nickel produced in the world was utilized for armament purposes. As a result of the research and development work that has been carried out since that time, both by the International Nickel Co. and its associates, and by nickel users throughout the world, the metal now enters into a wide variety of alloys and is employed to an increasing extent in nearly every industry. In 1922, the world consumption of the metal was only eight thousand six hundred tons, but this rose to seventy-five thousand tons last year, most of it for uses unconnected with war.

The new laboratories, which are magnificently housed, are fit to take their place among the more important organizations of their kind in the world. The structure is of reinforced concrete, and consists of a basement and three floors on a site 186 ft. × 43 ft. The building is faced with red brick, and a feature of the front elevation is a curved window extending the full height of the building and lighting the main staircase in the centre of the block. It is a pleasing example of modern architecture.

The opportunity has been taken to display the decorative qualities of some of the Company's products, and nickel alloy metal work is extensively used; the nickel-silver balustrade to the main staircase is particularly effective.

A notable feature of the laboratory is that it is heated and ventilated by the introduction of fresh warm clean and filtered air from a modern air-conditioning plant. This not only avoids the inconvenience of radiators in the laboratory, but also keeps the building free from dust. The automatic control of temperature and humidity thus obtained, as well as the freedom from dust, has definite scientific advantages, particularly in the corrosion laboratory, for the building is situated in the heart of industrial Birmingham where the atmosphere is at times very impure.

Service supplies of gas, water, electricity, etc., are led from the basement through enclosed longitudinal ducts and are distributed to the laboratories through channels in the walls and floors which are enclosed by flush-fitting panels. The benches are mainly tile-covered, and drainage channels are enclosed and hidden under the floor. The walls are finished in cream-coloured enamel and, being provided with big windows, make the rooms very light. The absence of pipes and fittings on the walls gives a general air of tidiness, which is further enhanced by the use of nickel alloy sink and other fittings. The general effect is rather that of a modern luxury bathroom than of a typical scientific laboratory.

A portion of the building is devoted to a large semi-technical laboratory, in which new processes can be studied on a larger scale, preliminary to their transfer to the works.

The general equipment of the laboratories is excellent, and the apparatus available for physical metallurgy is particularly to be commended. The wide variety of alloys of which nickel forms a component renders necessary a particularly wide range of testing appliances, and, except for an X-ray spectrometer, nothing of importance appears to have been omitted.

The laboratory is clearly designed principally for development work rather than pure scientific research; that is, it is intended to supply information, mainly obtained by known testing methods, to users of nickel alloys. For this purpose it is excellent, and it is doubtful if any better laboratory of the kind exists in Great Britain. There is, however, a certain rigidity about the lay-out of the building itself and of the apparatus which is perhaps not quite so desirable in a laboratory devoted to scientific research; but it is, perhaps, ungracious to criticize where there is so much to praise.

Development of the Scottish Highlands

The drastic depopulation of the Highlands, its causes and the possibilities of development form the subject of a broadsheet on the "State of the Highlands" which has recently been published by Political and Economic Planning. In 1931 the population of the Highland counties, which represent nearly 19 per cent of the area of Great Britain, was 356,615, or less than 1 per cent of Great Britain's population and 100,000 below the 1861 figure; nearly 40,000 of the shrinkage has occurred since 1921.

This depopulation is due partly to the poverty of the region in natural resources but also to political, social and economic handicaps. The Highlanders are extraordinarily poor. Crofting was formerly an adjunct to fishing, which has now in almost every area been killed by the trawlers, with consequent impoverishment not merely through loss of income but also through a change-over to a less satisfactory diet in which tinned and packaged foods figure prominently at higher cost. Deer-stalking has lately suffered a heavy eclipse, and grouse-shooting and fishing, while bringing in a certain amount of income, do little to benefit the mass of the population. Except for hydro-electric power development in connexion with the aluminium industry in the Kinlochleven and Fort William area, the natural resources of the area have not proved suitable for exploitation.

A high proportion of the occupied population is notoriously poorly paid, and the age structure of the population is becoming increasingly unsatisfactory, the proportion of persons in the age groups up to forty-five years being lower than for Scotland as a whole, especially in the groups below thirty years, while in the age-groups sixty-five–eighty years it is more than fifty per cent above the average. The marriage rate is well below the Scottish average, but the mobility of the population is greater than is often supposed. Transport charges are a serious obstacle to development, and ferry and other tolls are notorious.

The greatest possibilities of development lie in tourist traffic. More and better-run hotels, improved train and bus services, the encouragement of walkers as well as road touring, and maintenance of more adequate information and propaganda services should assist to attract the necessary money from outside. The tourist industry would also stimulate such other industries as sea-fishing, the cultivation of fruit and vegetables, and local handicrafts. Afforestation linked up with timber-processing, quarrying and wool are other possibilities, all of which demand leadership. Orthodox methods are inapplicable to Highland conditions, and the establishment of a form of Development Board through Parliament may be ultimately required.

Educational Topics and Events

ABERDEEN.—During the interregnum between the departure of Prof. James Ritchie to the University of Edinburgh and the arrival of a successor, the University Court has appointed Prof. Walter Garstang, formerly of the University of Leeds, to take charge of the Natural History Department in Aberdeen.

CAMBRIDGE.—The Managers of the Balfour Fund have made the following grants: to W. Graham-Smith, of Gonville and Caius College, £200 for an expedition to examine the Devonian fauna of Scaumenac Bay in Canada; to H. E. Hinton, of Fitzwilliam House, £200 for researches on the biology and distribution of the water-living insects of Lake Titicaca.

At Downing College, Sir Albert Seward, formerly Master of the College, has been elected into an honorary fellowship.

LONDON.—The following appointments have been made: Dr. W. G. Penney, Stokes student at Pembroke College, Cambridge, to be reader in mathematics in the Imperial College—Royal College of Science; Dr. Charles Reid, since 1933 lecturer in physiology at University College, London, to be reader in physiology at the London Hospital Medical College.

The title of professor of applied physical chemistry in the University has been conferred on Mr. G. I. Finch, in respect of the post held by him at the Imperial College—Royal College of Science. The title of emeritus professor of statistics in the University has been conferred on Prof. A. L. Bowley, on his retirement from the University chair of statistics at the London School of Economics.

The following awards have been made: George Smith studentship to T. J. B. Spencer (King's College); Graham scholarship in pathology to C. H. Gray; Loch exhibitions to Miss A. C. Anderson and Mrs. E. M. Pegram (London School of Economics); Metcalfe scholarship for women to Miss V. M. Rossitter; *proxime accessit*, Miss Adasia Steinberg; Metcalfe studentship for women to Miss G. H. Keir; Rogers prize to Dr. R. P. Kemp.

Dr. S. J. Davies, who has been University reader in mechanical engineering at King's College since 1926, has been appointed, as from January 1, 1937, to the University chair of mechanical engineering tenable at King's College.

MANCHESTER.—Prof. J. L. Stocks will vacate the Sir Samuel Hall chair of philosophy at the end of this term consequent on his appointment as vice-chancellor of the University of Liverpool.

The following resignations take effect from the beginning of the session: Dr. T. A. Bennet-Clark (lecturer in botany, appointed professor of botany at University College, Nottingham); Messrs. Frank Morton and L. W. Derry (demonstrators in applied chemistry in the Faculty of Technology).

The following appointments have been made as from the beginning of the session: Mr. A. C. Lovell, to be assistant lecturer in physics; Dr. R. F. Hunter, to be assistant lecturer in chemistry; Dr. V. J. Chapman, to be assistant lecturer in botany.

The Metallurgical Department has received a research grant from the International Tin Research and Development Council.

OXFORD.—Prof. A. R. Radcliffe-Brown has been appointed to the newly created chair of social anthropology as from January 1, 1937.

Prof. Frederick Soddy has intimated his desire to resign the Dr. Lee's professorship of inorganic and physical chemistry to which he was appointed in 1919.

In Convocation on October 27 the honorary degree of D.C.L. was conferred on President J. B. Conant, of Harvard University.

Congregation on October 20 accepted by 68 votes to 32 a scheme for altering the traditional rotation for the appointment of the vice-chancellor and giving the Chancellor wide powers of discretion. The aims of the scheme are to get younger men and longer term in office. Some of the promoters of it would have welcomed a permanent vice-chancellorship. Others, while preferring the present temporary appointment, would like to have it thrown open to any member of Congregation. The present feeling, however, is against these radical changes and in favour, merely, of making eligible for office any head of a college independent of his seniority. It is commonly agreed that the present vice-chancellor—the Master of Balliol—who happens to be one of the younger heads of a college, is the most successful one of recent years.

The numbers of those who took research degrees at Oxford in the past academic year have recently been published. They serve to show the main groups of subjects in which research is being carried out. They are—physical sciences: 45 B.Sc., 17 D.Phil.; biological sciences, 6 B.Sc., 6 D.Phil.; medicine, 2 B.Sc., 2 D.Phil.; social studies, 5 B.Litt., 4 D.Phil.; modern history, 12 B.Litt., 6 D.Phil.; all other subjects: 23 B.Litt., 4 D.Phil. Thirty-eight of the forty-five bachelors in the physical sciences are chemists.

Science News a Century Ago

Application of Statistics to Commerce

AT a meeting of the Statistical Society held on November 2, 1836, a paper "On the Application of Statistical Facts to Statistical Science" was read by W. Atkinson. After some preliminary remarks on the expediency of occasionally deviating from the leading regulations of the Society which limited the duty of members to the mere collection of facts, forbidding the expression of opinion, the author proceeded to show "by a critical comparison of numerous passages from the principal writers on the cause of wealth, as Smith, Say, Ricardo, M'Culloch, Scrope, etc., that their statements are involved in great confusion and contradiction ; that up to the present time, we were most lamentably destitute of any certain knowledge in the great branch of statistical science which relates to commerce ; and that in order that the principles of commercial economy may be established on a sure and certain foundation, they must be formed, not on *à priori* assumptions and definitions of vague abstractions, but upon positive facts to be observed, collected and arranged by the science of statistics". The paper led to an animated discussion as to whether statistics be, or not be a science, and also whether it should be an object of the Society not merely to collect statistical facts, but also to make inductions and draw conclusions from them. (*Athenæum.*)

Geology of Asia Minor

ON November 2, 1836, Hugh Edwin Strickland (1811–53) described to the Geological Society the general structure of Asia Minor, and in the course of his paper compared one region he had examined, with a part of France. Modern volcanic rocks, he said, were only observed in Catacecaumene in Lydia. The older cones, nearly thirty in number, were low and flat, and they were covered with vineyards producing the Catacecaumene wine celebrated from the time of Strabo to the present. There were great resemblances between this district and the volcanic districts in Central France. In both countries there are extensive lacustrine, tertiary deposits and volcanic cones extinct from the most remote historical antiquity.

Gray on Museums of Natural History

THE *Analyst* (5, 273) contains an interesting communication by John Edward Gray, F.R.S. (1800–75), entitled "Some Remarks on Museums of Natural History". The notice is dated Blackheath, November 5, 1836. Since 1824, Gray had been assistant zoological keeper at the British Museum, and was evidently well acquainted with museums both at home and abroad. He had recently visited the museum at Newcastle-upon-Tyne, where he had been "especially gratified with the liberality of the subscribers in throwing the Museum open, without the necessity of an introduction, or any charge to their fellow-townsmen—a facility of access scarcely to be expected except in a national establishment like the British Museum". Of other museums in the country, some were open by an order from, or an introduction by, a subscriber. At Liverpool, Edinburgh, Glasgow and Worcester, visitors were charged a shilling. At Manchester, however, Gray found the regulations very stringent, a notice board stating that no gentleman residing within three miles of Manchester, not being a subscriber, could be admitted, while servants and children were not allowed in. Commenting on this, Gray said, "I should have thought the admission of children, with a view of imparting a taste for the beauties of Nature in the rising generation would have been one of the ardent wishes of the subscribers". Referring to his visits abroad, he said he had "made notes of the various museums with the view of introducing into the British Museum any real improvement I might discover".

The Doctrine of Homœopathy

AT the Westminster Medical Society on November 5, 1836, Dr. Bureaud read a paper on homœopathy. "The Doctor," said the *Athenæum*, "appeared to have had great facilities for observing the peculiar mode practised by Hahnemann, its founder, and to have embraced every opportunity to gain information from its various disciples on the continent. He entered into a minute detail of the principles of the doctrine, critically analysed their merits, reported the results of various practical experiments, and concluded with a strong declaration, condemnatory of the practise. A letter was read from Dr. Poyntz, the physician of the Hotel Dieu at Lyons, reporting the *total failure* of Dr. Gerrard, a celebrated homœopathist of that city, who had selected thirty-two cases to be treated in that institution, on Hahnemann's plan and, after a trial of seventeen days, he had been obliged to resign their charge to the medical officers of the hospital, having been in every case, unsuccessful".

Statistics of Suicide at Aberdeen

THE *London Medical Gazette* of November 5, 1836, contains the following statistics of suicides at Aberdeen from 1826 until 1835 inclusive, drawn up by Dr. Francis Ogston. During this period, information was obtained about 52 persons who had seriously attempted suicide, of whom 38 had been successful. The number of attempts was the same in females as in males. The fatal cases among the former was 16 and among the latter 22. In men the actual were to the attempted suicides as 22 to 26, or as 1 to 1·18 ; in females as 16 to 26 or as 1 to 1·62. According to the census of 1830, when the population of Aberdeen was 58,019, there was one attempt annually in the ten year period in every 11,157·5 inhabitants. The age at which the greatest number of attempts was made was 21–25 years inclusive, and next in frequency the quinquennium 26–30 years. Among the men the greatest number of attempts was at 26–30 years, and among the women at 21–25 years. With one exception, after the age of thirty-five years, no ineffectual attempt was made. Attempts to take life by firearms (three cases) and by cutting instruments (six cases) were confined to males ; poison and drowning being the modes most frequently chosen by females. With one exception, when corrosive sublimate was swallowed, the poison selected was laudanum. Of the 52 suicides, 19 were married, 2 were widows, 1 was a widower and 30 were single ; 26 had no children and 16 had families, no information being available in 10. Suicides were most frequent in the last six months of the year, August standing highest with fifteen cases and May lowest with only two cases. As regards the habits of 30 in whom information was obtained, 20, or two thirds, were intoxicated and 10 sober ; 17 had the character of habitual drunkards.

Societies and Academies

Paris

Academy of Sciences, October 5 (*C.R.*, 203, 593–636).

Marin Molliard : The experimental production of variegation in the radish in a confined atmosphere enriched in oxygen.

Jacques de Lapparent : The interpretation of radiograms of crystalline powders based on results obtained with argillaceous phyllites.

Ottokar Borůvka : Singular matrices.

Alexandre Ostrowski : A transformation of the Liouville-Neumann series.

Maurice Gevrey : Certain systems of partial differential equations with multiple imaginary characteristics.

Pierre Ernest Mercier : The most general symmetrical suspension.

André Couder : The photographic measurement of the atmospheric disturbance of stellar images.

René Lucas : The diffusion of elastic waves in fluids.

Edmond van Aubel : Hall's phenomenon in antimony–tellurium and antimony–silver alloys.

Mme. Dorothy Moyle Needham : The phosphorylation of cozymase. It is concluded that the phosphoryl compound of cozymase, a compound containing easily hydrolysable phosphorus, is formed in muscle extract as the result of a reaction with phosphopyruvic acid.

Bertrand Goldschmidt : The coefficient of fractionation of radium and its isotopes in the crystallization of barium chlorate.

Marcel Prettre : The inhibition by hydrogen of the chain reaction of mixtures of normal pentane and oxygen. Hydrogen hinders the oxidation and inflammation of pentane, whilst an inert gas, such as nitrogen, facilitates the combustion under the same conditions.

Thadée Urbanski and Marion Slon : The nitration of some normal paraffin hydrocarbons. The direct formation of nitro-paraffins has hitherto been possible only with hydrocarbons higher than pentane. The authors have obtained nitromethane and nitropropane by the direct action of N_2O_4 upon the hydrocarbons.

Georges Dupont and Victor Desreux : Contribution to the study of β-myrcene. Hydrogenation by sodium and alcohol.

Pierre Lesage : A general review of ten years of culture on acquired and inherited precosity.

Raoul Lecoq : Disturbance in the food balance by the introduction of uric acid or oxalic acid into the ration of the pigeon.

Albert Berthelot and Mme. Germaine Amoureux : The tumours obtained by inoculating *Bacterium tumefaciens* aseptically into seedlings and young cultivated plants.

Albert Peyron and Henri Limousin : Polyembryony in tumours with multiple tissues of the testicle in man.

Maurice Caullery : Remarks on the preceding communication.

Gaston Ramon, André Boivin and Rémy Richou : The flocculating and immunizing properties of anatoxins purified by precipitation with trichloracetic acid. The diphtheric and staphylococcic anatoxins can be purified by the trichloracetic acid treatment without losing their immunizing properties.

Copenhagen

Royal Danish Academy of Sciences and Letters, March 20.

Johs. Hjelmslev : (1) Projective triangle invariants. (2) Introduction to the general doctrine of congruence (third communication).

April 3.

Ad. S. Jensen : *Eriocheir sinensis* from southern Jutland. A review of the immigration of the Chinese mitten crab into Denmark.

April 17.

E. Biilmann : An optically active deuterocamphane.

May 1.

J. N. Brønsted : Relation between heat and work. The thermodynamic postulate that heat cannot be transformed into work without a simultaneous occurrence of compensating changes in the surroundings should be modified into the claim of the general impossibility of a conversion of heat into work. This demonstration leads to a somewhat modified formulation of the fundamental thermodynamic laws.

Harald Bohr : The theory of almost periodic functions (6). Picard's theorem.

May 15.

August Krogh : A new bottom-sampler for investigation of the microfauna of the sea bottom. With remarks on the quantity and significance of the benthonic microfauna.

G. Hevesy : Splitting of atomic nuclei under the influence of neutrons on rare earths. Neutrons are easily intercepted by most atomic nuclei, and the interception often leads to the formation of another element or of a heavier atom of the same element, a heavier isotope ; both may be either radioactive or stable. The investigations of the influence of neutrons on rare earths carried out at the Institute for Theoretical Physics in collaboration with Dr. Levi showed that all rare earths are able to absorb neutrons. Under the influence of the neutrons a great number of radioactive isotopes, hitherto unknown, has arisen. The periodicity of these, and the intensity and hardness of the β-radiation emitted, have been investigated. The radioactivity of the rare earths can be utilized for the demonstration and quantitative analysis of these substances.

Moscow

Academy of Sciences (*C.R.*, 3, No. 3 ; 1936).

G. Fichtenholz : A generalization of the Stieltjes integral.

L. Kantorovič : General forms of certain classes of linear operations.

S. Sobolev : Correction to the paper "On some evaluations concerning the families of functions having derivatives with integrable squares" (cf. *C.R.*, 1, No. 7 ; 1936).

B. Vulich : Correction to the note "Some remarks to the theory of K-normed space" (cf. *C.R.*, 2, No. 2 ; 1936).

L. Mandelstam and M. Leontovič : Supersonic absorption in fluids and certain optical phenomena connected with it.

J. Larionov and A. Seidel : Fluorescence of the salts of trivalent europium in aqueous solutions.

M. Veingerov: The limits of sensitivity of a radiometer based on the principle of a gas thermometer.

D. Mirlis and P. Rehbinder: Kinetics of selective wetting and surface reactions on metals in presence of electrolytes (1).

W. I. Vernadsky: Variations in the atomic weights of chemical elements on the earth.

M. Iljinskij and W. Afremov: Inhibiting agencies in the chlorination of anthracene. Influence of the composition of the solvent on the course of the reaction.

P. Kapterev: Experiments in the revitalization of organisms from permanently frozen subsoil (see Nature, Oct. 24, p. 714).

N. L. Gurvič: The diversity of composition of essential oils in certain species of the Transcaucasian thyme.

Rome

Royal National Academy of the Lincei (*Atti*, 3, 383–458; 1936).

G. Checchia-Rispoli: The Pliocene echinoderm fauna from the neighbourhood of Lentini (province of Syracuse).

U. Broggi: Determinant functions.

B. Segre: Varieties of Veronese with two indices (2).

B. Manià: Complete equations in the problems of Lagrange.

E. Gugino: Single deduction of the dynamic equations of Maggi and of Appell (1). Dynamic equations of Euler-Lagrange according to G. Hamel (2).

C. Jodi: Formula for the increase of a vibratory motion constrained by harmonic forces.

G. Lampariello: Application of the method of images to vortex motions.

C. Tagliacozzo: Observation on the kinetostatics of elastic systems.

E. Volterra: Plane elastic arcs (1). Differential equations of the deformations.

G. R. Levi and A. Baroni: Carbon obtained by the dehydration of carbohydrates.

G. Natta and M. Baccaredda: Examination of cellulose by means of electron rays.

P. Principi: The age of some formations of the Appenines.

M. Mitolo: Oxidation-reduction phenomena and states of functional activity of the neuraxis.

Washington, D.C.

National Academy of Sciences (*Proc.*, 22, 463–523, Aug. 15).

Fred M. Uber and T. H. Goodspeed: Micro-incineration studies (3). Shrinkage phenomena during carbonization and ashing of wood. A hot-stage microscope was devised; an aluminium chamber, 25 mm. × 50 mm., was wound with resistance wire, and temperatures up to 650° C. were available. With this apparatus, sections of wood 5 μ thick were observed while incineration was proceeding.

W. A. Setchell and N. L. Gardner: *Iridophycus gen. nov.* and its representation in South America.

Frank H. Clark: Linkage relations of hydrocephalus (hy_1) in the house mouse, *Mus musculus*. No linkage was observed with 15 characters marking 14 of the 20 chromosomes of the mouse.

H. C. Sherman and H. L. Campbell: A further study of regularity of nutritional response to chemical intake. Animals reared for eight generations on a minimal adequate diet responded to enrichment of diet in calcium, vitamins A and G and protein by increased rate of growth and vitality.

John M. Ide: The elastic properties of rocks: a correlation of theory and experiment. The modulus of rigidity and Poisson's ratio for a series of rock samples prepared by the Committee on Geophysical Research at Harvard were determined by dynamic methods (see Nature, 137, 675; 1936). Elastic constants determined in the laboratory are compared with those derived from theoretical formulæ. Agreement is good for steel, copper and diabase; other materials showed varying discrepancies, suggesting that the rocks studied are imperfect elastic media. The theory of elasticity can be applied safely to the fine-grained igneous rocks presumed to underlie the oceans and continental granites; but not to surface rocks, whether sedimentary or granitic in character.

Francis P. Shepard: The underlying causes of submarine canyons. Examination of recent data on these canyons leads to the following suggestions. Before the glacial period there were depressions on the continental slopes, due to various causes. Next, during the maximum of a glacial epoch, the sea was lowered some 3,000 ft. by ice formation, and these depressions were occupied by rivers which cut true river canyons through relatively recent sediments. With the melting of the ice, the sea rose, submerging these canyons, which are kept clear by mud flows and submarine currents.

C. A. G. Wiersma and George Marmont: Mechanism of inhibition of crayfish (*Cambarus clarkii*) muscle. Evidence was obtained of two inhibition mechanisms, one working directly on the contractile elements and the other influencing the action currents.

Emil L. Smith: Photosynthesis in relation to light and carbon dioxide. Experiments with a freshwater plant, *Cabomba*, in buffer solution exposed to light intensity range of 1 to 1,700, provided data from which curves relating photosynthesis to intensity were drawn. The results of other workers on limited intensity ranges fit the equation derived from this curve. Photosynthetic rate appears to the same function of both light intensity and carbon dioxide concentration.

Kenneth V. Thimann: Physiology of the formation of nodules on legume roots. Experimentally it is found that nodules produce an auxin. Local application of auxin to young lateral roots of a legume inhibits their growth in length, but causes a swelling at their base due to increase in size of cortex cells. It is suggested that the nodule bacteria within the plant produce an auxin, which causes cell enlargement and also the early stages of a lateral root; growth of the latter is inhibited but cell enlargement continues, giving the characteristic nodule.

E. G. Boring and S. S. Stevens: The nature of tonal brightness. Analysis of the frequency spectra of sounds emitted by cardboard sirens suggests that brightness is associated with the presence of higher harmonic partials and depends on the velocity of the air blast, but not on the ratio of size of hole in siren disk to size of interval between holes. Brightness is probably better regarded as density.

A. A. Abramowitz: The action of intermedin on crustacean melanophores and of the crustacean hormone on elasmobranch melanophores. Pituitary extract causes restoration of dark coloration in eyeless fiddler crabs, just as crustacean pigmentary hormone restores that of dogfish (*Mustelus*) from which the pituitary gland has been removed.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, November 2

Royal Geographical Society, at 3 and 8.30.—Hugh Ruttledge: "The Mount Everest Expedition of 1936".

London School of Economics and Political Science, at 6.—A course of lectures on "Current Problems of Business Administration" (succeeding lectures on November 9, 16, 23, 30, December 7, January 11, 18, 25, February 1, 8, and 15).*

Tuesday, November 3

Institution of Civil Engineers, at 6.—Opening Meeting.

Sir Alexander Gibb: Presidential Address

Wednesday, November 4

Royal Society of Arts, at 8.30.—Sir Henry McMahon. "180 Years of Pioneer Work by the Royal Society of Arts".

Thursday, November 5

Royal Society, at 4.30.—O. A. Saunders: "The Effect of Pressure upon Natural Convection in Air".

R. A. Bagnold: "The Movement of Desert Sand".

J. Smiles and H. Wrighton: "The Micrography of Metals in Ultra-violet Light".

Royal College of Physicians, at 5.—Dr. J. D. Rolleston: "The History of Measles" (FitzPatrick Lecture).

University of Leeds, at 8.—Prof D. T. Suzuki: "Buddhism in the Life and Thought of the Japanese People".*

Chadwick Public Lecture, at 8.15—(at the Royal Society of Arts, John Street, Adelphi, W.C.2).—Robert R. Hyde: "Industry's Contribution to Public Health: Firms' Voluntary Medical Services" (Malcolm Morris Memorial Lecture).*

Friday, November 6

Institution of Mechanical Engineers, at 6.—Prof. Alfred Fowler, F.R.S.: "The Spectroscope and the Atom" (Thomas Hawksley Lecture).

North East Coast Institution of Engineers and Shipbuilders, at 7.—Sir Frank Smith, F.R.S.: "Sir Charles Parsons and Steam" (Parsons Memorial Lecture).

Royal Institution, at 9.—Prof. F. A. Paneth: "The Chemical Exploration of the Stratosphere".

Empire Co-operation in Agricultural Research

THE term 'scientific' applied without qualification to the British Commonwealth Scientific Conference held on September 21–October 8 is scarcely accurate. Only a part of the machinery of science was under consideration : that part, especially of the sciences relating to agriculture, which is organized on a co-operative basis between the Governments of the British Commonwealth. The delegates to the Conference were mostly those concerned with the administration of Government scientific departments or of national research organizations ; few were persons actively engaged in scientific work themselves.

Even within these limits, the field covered was a large and interesting one. Scientific co-operation of the kind that the Conference reviewed began in London, with a group of African Colonies that had a common interest in the development of knowledge of insect-borne diseases. The Entomological Research Committee set up by the Colonial Office in 1909 became a few years later the Imperial Bureau of Entomology, established on a wide basis of Empire co-operation and charged with the documentation of entomological knowledge and the identification of insects injurious to man and to his crops and stock. This was followed in 1920 by the formation of a similar, jointly maintained, central organization to deal with the fungi and bacteria that injure crops or are otherwise of economic importance—the Imperial Bureau of Mycology. As a result of the Imperial Agricultural Conference of 1927, eight new Imperial Agricultural Bureaux were established to cover the subjects of soil science, animal health, animal nutrition, animal genetics, plant genetics (other than herbage), plant genetics (herbage), fruit production and agricultural parasitology. At the same time the two older Bureaux became Institutes, as they had functions considerably wider than those assigned to the eight new Bureaux, which confine themselves to the collection and dissemination of information. The new Bureaux are attached to research institutes in their subjects at Rothamsted, Weybridge, Aberdeen, Edinburgh, Cambridge, Aberystwyth, East Malling and St. Albans, while the two older bodies are in close contact with the Natural History Museum, South Kensington, and the Royal Botanic Gardens, Kew, there being no research institutes specially devoted to entomology and mycology in Great Britain.

The activities of these ten organizations, a survey of which formed a major part of the work of the Conference, has recently been described in considerable detail in the seventh Annual Report of the Executive Council of Imperial Agricultural Bureaux*. The Council comprises representatives of the United Kingdom, of each of the five Dominions, of India, Southern Rhodesia, and the Colonial Empire. It administers a service of common Empire interest maintained from a fund jointly subscribed by all the members of the British Commonwealth. The acceptance by Governments of the scheme proposed by the 1927 Conference and extended by the Skelton Committee on Economic Consultation and Co-operation which followed the Ottawa Conference a few years later, brought into being a new type of Imperial organization. A glance at the Council's recent report, which indeed will well repay careful reading, indicates how rapidly the service thus set up has expanded and how clearly it seems in most cases to have met a need.

---

* Imperial Agricultural Bureaux, Seventh Annual Report of the Executive Council, 1935–1936. Pp. 102. (London: H.M. Stationery Office, 1936.) 5s. net.

The primary function is information. The world literature on the subject with which each Bureau or Institute deals is surveyed and in the main abstracted. The aim in most cases is to miss nothing, no matter where or in what language it sees the light. The *Veterinary Bulletin*, published by the Imperial Bureau of Animal Health at Weybridge, noticed some 3,000 papers in its last annual volume. Early notice and sufficient detail to be of value to the worker who may be unable to secure or read the original paper are the keynotes of the service, the machinery for which has now been brought in most cases to a high level of efficiency. Special reports, in which the whole of the available literature on some particular subject is digested, are a feature of several of the Bureaux ; technical communications and bibliographies of others. Translations or long abstracts are provided by some, while several maintain lending libraries available throughout the Empire, and all are prepared to answer inquiries to the best of their ability. The two older Institutes are characterized, in addition, by a considerable organization for the identification of insects and fungi.

Visiting parties from the Conference spent much time in examining the work of these ten Bureaux and Institutes, and also in considering the possibilities of extending the organization to cover other fields, especially those of dairy science and forestry. What conclusions have emerged from the subsequent discussions in plenary session will, no doubt, become known in due course. At least one may hope that the report to Governments will recognize how much easier has been made the path of the research worker in many branches of agricultural science in knowing what has been and is being done in his chosen field, and thus set off, against the danger of superficialism to which such 'crammed' knowledge might lead, the increased efficiency that must come from the early and wide dissemination of the results obtained by other workers. It is a fair claim that in this kind of organization the British Commonwealth at present leads the world.

In its touring programme the Conference did not confine itself to these joint enterprises. Several of the agricultural, veterinary and dairying research institutes were visited and also some of those under the Department of Scientific and Industrial Research, and the Imperial Forestry Institute at Oxford. In all cases the inter-Imperial aspects of the work came under notice, but evidently more as a guide to the development of research in the various countries of the Commonwealth, than with a view to the extension of jointly financed research projects. Co-operation in Empire research, as distinct from the documentation of research, is tending more in the direction of interchange of programmes and personnel and the holding of conferences than in centralization of staffs and joint finance. It cannot be doubted that this is a healthy sign of the vigour of scientific development overseas, but it is equally clear that important research work is waiting on facilities that no single part of the Empire has as yet felt impelled to provide. Exceptionally there has been financial co-operation in research schemes on subjects such as the transport and storage of foodstuffs and locust investigations, centred at institutions in England, and proposals were before the Conference for a joint investigation into the control of termites. Usually, however, the investigational work done at a central station in the special interests of an overseas Government is paid for by an *ad hoc* grant from that Government, and such work is necessarily limited to problems on which some institute in the country is already engaged.

Considerable as is the field covered by the inter-Imperial organizations now in being, these limitations in their scope are leaving untouched many fundamental investigations that may not be urgent in any single member of the Commonwealth but are of great importance to the whole.

Another aspect of the Conference that should be mentioned was the emphasis laid on the value of the contacts established through the holding of periodical meetings not only of those charged with the direction of research but also of the actual workers in the different fields of applied science. Imperial Conferences are already held in a few subjects at intervals of five years or so, and an extension of this principle seemed to be indicated. Perhaps the greatest value of the Conference just concluded has been the opportunity it gave to members of getting to know the personalities and interests of their 'opposite numbers' in other parts of the Commonwealth and thus to secure a spirit of co-operation that is beyond the reach of official agencies.

A Social Analysis

The Anatomy of Frustration:
a Modern Synthesis. By H. G. Wells. Pp. 274. (London: The Cresset Press, Ltd., 1936.) 7*s.* 6*d.* net.

TO the generation of readers immediately preceding the Great War, H. G. Wells (as a member of a deputation remonstrated with the Minister of Fine Arts, "On ne dit pas Monsieur Renoir, on dit Renoir") was the great illuminator, revealing the power of science to transform the material world, but on the men of science themselves his action has been different. He has awakened them to a consciousness of social disorder, disorder remediable by the application to mankind of the methods by which science is learning to control the other departments of Nature. In the laboratories either of the universities or the works, in the shops wherever the technicians congregate, the talk and thought are permeated by Wells, even though the participators have never read one of his books. Some of these men get labelled 'communists' because of their impatience with current government by slogans and the canons of good form; others incline to Fascism in the hope that a dictator would get things done. Even Wells has flirted with the Fascist idea of the need of a great man, though his leader would be the entrepreneur who had proved his quality in big business. Whatever the particular manifestation may be, the young workers in science to-day no longer regard 'politics' as unworthy of their interest; they are looking for social reconstruction directed by science, and consciously or not, Wells has been the catalyst that has initiated the reaction.

In this latest book "The Anatomy of Frustration" Wells adopts an odd technique. He puts his opinions into the mouth of Mr. Steele—inventor and business man, who after the War had retired to the south of France in order to sort out his ideas about life. This gives Wells the opportunity of a running commentary and of anticipating in advance the scepticism which is part of the outfit of the man of science. He explains his title; Burton's "Anatomy of Melancholy" was an analysis of the despair with which the thinking man of his epoch must regard the world—a universe wholly and irremediably mad. Steele embarks on his examination of frustration in the modern world with the firm determination that a remedy can be found by the methods he has found valid in that section of which he had experience. He starts with a brave assumption—that all men can and ultimately will think very much alike: "Men have no right to a thousand contrasted faiths and creeds and . . . the multitudinousness of people in these matters is merely due to bad education, mental and moral indolence, slovenliness of statement and the failure to clinch issues"; and so we pass on to a discussion of religion and immortality, and of morality that needs re-expression in terms of daily life.

> "Motives are things of deeper origin than intellectual convictions and the real will of *Homo sapiens* is still largely unaffected by his conscious and formulated wishes. His intentions are one thing; his behaviour quite another. The world's expressed desire, its conscious desire, is such and such; the total complex of human impulses is quite another system, darker, deeper and profoundly more real. These desires for world unity and sane economics are conscious and intellectual desires, and they scarcely penetrate at all into the more primitive and substantial mental mass which is the true reservoir of motives and impulses."

But for all that, Steele is not prepared to yield to the sub-conscious—"The essential purpose of all law, all discipline, all training, is the enthronement of a clear general purpose above a subjugated and directed subconsciousness".

Steele would not be Wells if he did not knock a good many heads along his route; socialism is a case of "habitual piecemeal thinking"; "the Moscow frustration is a study in the deterioration of yet another blazing star of hope"; "the League of Nations recognises, intensifies, and does its utmost to preserve the conventions of nationalism and the emotions of patriotism"; schools and colleges are to this day "conducted to put back the new generation where its parents began". Steele has no use for all sorts of things—The People, Zionism and other separatist movements ("Why specialise in Erin and Mother India and Palestine, when the whole world is our common inheritance. *Come out* of Israel"), Liberalism ("The stupid can co-operate loyally upon immediate objectives; the intelligentzia, it seems, cannot co-operate at all"), and the artistic temperament ("Indulgence of appetites to the detriment of fitness and the distraction of energy").

Is there nothing constructive about Steele? He attaches extraordinary importance to the production of that 'World Encyclopædia' of his. It seems to him that it is "the most urgent need of our time. The main intellectual task of education is to put before the expanding mind everything that is clearly known about the nature of the world in which it finds itself". Of such is to be the new education, and we may suppose that it was under the urge of Steele that Wells set about the "Outline of History", and the "Science of Life", as samples of that great and continuous synthesis the World Encyclopædia is to be. And so Wells ends as he has begun and continued—a solvent and a loosener of mental inhibitions, for until freedom is obtained no orderly co-operation of men with men can proceed. "Fine confused thinking" perhaps, but how stimulating; it is better to clear the mind than to trim it into a system.

A. D. HALL.

Wild Animals at Large

(1) Hunting Wild Life with Camera and Flashlight:
a Record of Sixty-five Years' Visits to the Woods and Waters of North America. By George Shiras, 3d. Vol. 1: Lake Superior Region. Pp. xxiv+450. Vol. 2: Wild Life of Coasts, Islands and Mountains. Pp. x+450. (Washington, D.C.: National Geographic Society, 1935.) 2 vols., 5 dollars.

(2) La vie des animaux sauvages de l'Afrique
Par Dr. Émile Gromier. (Bibliothèque géographique.) Pp. 343+36 plates. (Paris: Payot et Cie, 1936.) 40 francs.

(3) Parade of the Animal Kingdom
By Prof. Robert Hegner, assisted by Jane Z. Hegner. Pp. vii+675. (New York: The Macmillan Co., 1935.) 21s. net.

THE art of the camera seems almost wholly to have displaced that of the pen and pencil in the illustration of popular works on animals, and these three books, dealing with wild life in their own special ways, owe a large share of their attractiveness to the photographs which, apart from a couple of maps and a rough sketch, are their only pictures.

(1) The first is an outstanding work of its kind, and must be looked upon as a classic in the history of wild life photography. Its author, George Shiras, born in Pittsburg in 1859, is the pioneer of American Nature photographers. Laying aside the gun for the camera in 1889 he was, according to E. W. Nelson, former chief of the U.S. Biological Survey, the first to photograph animals from a hide in daytime, to make wild animals take their own photographs by operating the camera shutter during the day and with flashlight at night, to use two flashlights and two cameras so that the first caught the wild creature at rest and the second at the moment of its alarm, and the first to practise wing-shooting by means of a specially mounted camera which enabled him to photograph wild fowl flying at great speed. The cinematograph has displaced the camera for some of these purposes, but it has not done more beautiful work than some of the still pictures made by Shiras with his simpler apparatus.

In other ways the author has been a champion of wild life in the United States: his observations and his advocacy led the movement for the preservation of disappearing birds and beasts and for the establishment of national reserves, as they lay at the foundation of the Federal Migratory Bird Law and the Migratory Bird Treaty in which Great Britain co-operated. The articles which make up these two volumes have appeared from time to time in the *National Geographic Magazine*; here they are revised, with much new matter and previously unpublished photographs added. They are chatty, straightforward accounts of the author's long experience of wild life in various parts of North America, and discuss the habits of a great range of animals. The articles are illustrated by striking photographs, none of which could exceed in beauty the pictures of some of the fungi which accompany the article on "Camp Flowers in Northern Michigan".

(2) Dr. Gromier unites in himself two apparent incompatibles, the enthusiastic protector of wild life whose ardent desire is that the nations should unite to conserve the unique fauna of Africa, and the sportsman who on occasion bags the outstanding trophy when it presents itself. He offers advice to sportsmen on the preparation necessary for long journeys in wild country and on the choice of arms and ammunition, and follows his advice with hints upon the photography and filming of wild animals. Photography bulked largely in his own expeditions, and his photographs, although many show signs of amateurish retouching, add to the interest of the text, and indicate the author's intrepidity in the presence of the most dangerous of Africa's big game.

The author gives vivid accounts of journeys in pursuit of elephant, rhinoceros, hippopotamus, lion, buffalo, eland, giraffe and gorillas. To each of these is given a chapter recounting such habits as came under observation, but the observations do not add much to the already fairly extensive knowledge of the fauna. The author had the good fortune to observe and photograph an albino elephant in Cameroon, and his encounter, twenty-five years ago, must be one of the first records of the nightly nests or platforms of branches built by the gorillas of Kivu, some solitary, some grouped, and some apparently built for two individuals, but all defiled by the excrement of their tenants. An interesting feature is the reproduction of forty-three illustrations showing the spoor of various creatures.

(3) Dr. Hegner's book is of a type different from the two preceding. It is not a work of personal experience, but an account, meant for the layman, of many characteristic representatives of the various groups of animals. The account is systematic in that it follows the recognized sequence from Protozoa to the higher monkeys, but its method is unconventional, and the simplicity and liveliness of its language, the beauty of its photographic illustrations by experts and specialists, and its avoidance of technical terms in description and even in naming (scientific nomenclature is omitted), will commend it to many who wish to obtain an accurate and wide but not technical knowledge of the animal kingdom. J. R.

World Weather

Manual of Meteorology
By Sir Napier Shaw, with the assistance of Elaine Austin. Vol. 2: Comparative Meteorology. Second edition. Pp. xlviii+472. (Cambridge: At the University Press, 1936.) 36*s*. net.

THE four volumes of Sir Napier Shaw's monumental "Manual of Meteorology" bear the titles: (1) "Meteorology in History"; (2) "Comparative Meteorology"; (3) "The Physical Processes of Weather"; (4) "Meteorological Calculus: Pressure and Wind". Vol. 2, which after eight years now appears in second edition, gives in a descriptive form our present-day knowledge of the weather all over the world. Sir Napier's comprehensive view of this subject has taken its most perspicuous form in a great number of charts dealing with the entire earth, in most cases given in polar projection for the northern and the southern hemisphere separately. These charts have since their appearance in 1928 exerted a great influence upon the views of meteorologists, and selected samples of them have been reproduced in more than one of the text-books published since that date.

Referring to the great amount of new observational data which has become available during the last eight years, Sir Napier says in his preface: "A complete revision of the representation of meteorological data from the point of view of 1935 instead of 1927 is not possible". As regards diagrams and charts he has, therefore, with good reason limited his efforts to correcting errors and omissions, and substituting a small number of new figures for old ones. The most important new features are discussed in a concluding chapter of "Notes and Supplementary Tables". Characteristic of Sir Napier's sense of humour, this exceedingly useful chapter is headed by the device: "The end must justify the means". These notes show as a matter of fact how Sir Napier still follows with the keenest interest the progress of his science in every detail.

After consideration in Chapter vii of changes in the general atmospheric circulation, Chapter viii and the subsequent chapters deal with the description of the transitory changes in weather conditions, including the description of cyclones and anticyclones. This is a field of rapid scientific progress, and here the greatest changes in the new edition are found. I believe that I can see one of the leading ideas of Shaw's own work reflected in his description of Sir Francis Galton's admirable contribution to the study of transitory changes. On p. 374 we read these characteristic lines, which appear for the first time in the new edition:

"The possibilities of these records have never been explored but their use still remains an obvious responsibility to British meteorologists. It is rather pathetic to remember that after reproducing actual curves for twelve years with all the machinery for continuing the practice the experts at the time preferred the tabulation of five-day means of hourly values and the passing of the original curves through a mechanical harmonic analyser. Every page is suggestive to those who have opportunity of studying it."

I would give these words my full approbation. Sir Francis Galton's records (*Quarterly Weather Report* for the years 1869–80) are a gold-mine which has remained almost unexploited. As an example how they may inspire useful work even to-day, I may refer to a note just recently published by Dr. T. Bergeron, "L'Utilisation des 'Météorogrammes' pour les recherches synoptiques" (*Assoc. Meteor. l'U.G.G.I.*). Speaking of the Galton records he says: "Voila la plus admirable publication de données météorologiques existante !"; and he justifies these words by giving some examples of how the results found in recent years by the highly developed modern weather-chart analysis might have been found with greater ease sixty years ago by the Galton records combined with the weather charts of those days.

But meteorologists did not find this most direct way. The method of averaging directed attention away from the minute examination of individual cases. It is a great merit of Sir Napier that, in spite of all, he never lost his interest for the individual case. He succeeded in understanding the records more fully than his predecessors. A typical protest from his side against the tendency of making all characteristic features disappear by the formation of averages is represented by Fig. 218 (Fig. 211 of the first edition), showing his view of the structure of a cyclone. I have always admired this figure, which appeared almost as a joke, and which ultimately has showed itself to contain so much of concealed truth.

Readers of Sir Napier Shaw's "Manual" will find a special charm in the bold but striking statements so frequently met with in all his writings. The reading of the more than 1,500 pages of his great work, therefore, never becomes dull. This is certainly one of the reasons why the second edition comes so soon after the first one. Sir Napier Shaw is to be most heartily congratulated on the well-deserved success of his great work.

V. BJERKNES.

Geography and Distribution

Plant and Animal Geography

By Dr. Marion I. Newbigin. Pp. xv+298. (London: Methuen and Co., Ltd., 1936.) 12*s*. 6*d*. net.

BY the death of Dr. Marion Newbigin in 1934, geographical science suffered a serious loss. Fortunately her book on biogeography was being prepared for the press, and with the co-operation of Miss Florence Newbigin and Prof. H. J. Fleure, who revised the work, it has now been published.

On such complex problems as the distribution of animals and plants, and the means by which it was brought about, Dr. Newbigin was able to take a broad outlook. Her view was almost detached. She possessed a certain clarity of mind, which enabled her to distinguish between general principles and details; and a power of lucid expression rare among scientific writers. The result is this clear and readable book.

To the student of distribution, one of the main difficulties to a clear understanding of the problem is the fact that, while the geographical causes (in the strict sense) remain constant, the results are very different, mainly owing to the different means available for dispersal. That is to say, the same barriers, ocean, desert, mountain range, and the same land bridges, exist for animals as for plants; yet they operate in very different degrees. Nevertheless, we should expect to find some correspondence at least between the distribution of animals and plants; and it is this which Dr. Newbigin brings out clearly.

Beginning with a general description of the higher forms of life in relation to environment, the author passes on to an outline of taxonomy—not in itself a concern of the geographer—and thence to a description of the principal plant communities with their animal complements. These studies prepare the student for the most important chapters in the book, those dealing with the major faunal and floral regions of the world. Here Dr. Newbigin is at her best. She tries, with considerable success, to reconcile the divergent views of botanists and zoologists as to the main biogeographical regions, while recognizing that complete reconciliation is not possible. As she points out, there is not the same unanimity among botanists that there is among zoologists as to how the earth should be divided. Even if the former confines himself to the flowering plants, his present material is enormous, and the geological record less perfect than it is for mammalian remains. With regard to this last, however, the author is perhaps unduly pessimistic. The fact that there are vastly more flowering plants than there are mammals, while making the problem more difficult, increases the chance of fossil remains being found; and it would indeed be strange if plants—even herbaceous ones—had failed to leave clues which the ingenuity of scientific investigators could follow up. One key to the identification of recent floras has been found in their seeds; and the work of Mrs. E. M. Reid on Pliocene floras in western Europe confirms that of other palæobotanists that, since Tertiary times, plants, like animals, have followed a general southerly direction. It is possible that we know almost as much about Pleistocene floras in Europe as we do of Pleistocene mammals.

In stressing the importance of mountain barriers, such as the Himalaya, to animal and plant migration, the author is apt to overlook the fact that, so far as plants are concerned, they act as carriers as well as barriers. The east to west distribution of alpine plants is to be ascribed to the great Tertiary uplifts of Eurasia; and this movement has to some extent masked the north to south movement, further complicating the problem for the botanist. But the Himalaya was certainly most effective as a barrier just at the most critical time, namely, during the glacial epoch, when great numbers of species which might otherwise have made good their escape southwards, found their way barred, and perished. Almost unconsciously, as it appears, Dr. Newbigin pays tribute to the general truth of Willis's 'Age and Area' hypothesis; for on p. 216 we read: "Thus the problem of distribution for any type seems to resolve itself into the time factor, the length of time which has elapsed since its origin, and the checking factor . . ."

In the opinion of the reviewer, this is the best general account which has appeared for some years of plant and animal distribution, its causes and consequences. The book is well printed and adequately illustrated; although it might be as well to add a map in any future edition showing at least the fourteen botanical regions commonly accepted by geographical botanists. Only the expert can correlate these for himself with the zoological map facing p. 244.

Mélanges Pelseneer

Mélanges Paul Pelseneer
(Mémoires du Musée Royal d'Histoire Naturelle de Belgique, Deuxième Série, Fasc. 3). Pp. ii+1206. (Bruxelles: Musée Royal d'Histoire Naturelle de Belgique, 1936.) n.p.

THIS handsome volume, containing contributions from among the most distinguished of his fellow workers in eleven countries, is dedicated to the eminent zoologist Paul Pelseneer "en témoinage de profonde reconnaissance et de respectueux admiration". Although he is pre-eminently a malacologist, his interest in all aspects of zoology is well known, and there are few groups in which he has not worked. A knowledge of this interest is manifest in the wide range of subjects chosen by the sixty-six authors represented, for nearly every animal group is included, from Protozoa to man, and each contributor choosing the subject specially his own in many cases has chosen one already in some measure touched upon by his illustrious colleague.

Not only in malacology but in the general papers also this interest is felt. Strohl's work on bipolarity is a case in point, and the paper by Pérez dealing with the influence of trematode sporocysts on the genital glands of *Turritella* recalls to us the fact that Pelseneer has himself investigated the larval trematodes parasitizing various molluscs, and has recorded several new species. In this connexion also comes Van den Berghe's ecological account of Congo molluscs as hosts for trematode cercariæ. It is the same with the Crustacea. Among the four papers dealing with this group, Redeke, in his research on *Atyaephyra desmaresti*, follows in the footsteps of Pelseneer, who was the first naturalist to record this species from Belgium.

Naturally the molluscs predominate, twenty-four of the contributions being devoted to them. To select two bearing specially on Pelseneer's own work we may mention Odhner's extensive paper on the Nudibranchia Dendronotacea, emphasizing our indebtedness to that author's exact investigations which afford such a solid basis for a modern natural classification, and Orton's observations and experiments on sex-change in the European oyster *Ostrea edulis*, in which he acknowledges "inspiration and advantage from this distinguished and honoured colleague". Yonge, on the evolution of the swimming habit in the Lamellibranchia, has chosen a subject peculiarly his own; and Navez, in his observations on the cardiac rhythm of *Anomia simplex*, offers a very interesting subject in a totally different field.

Four papers deal with echinoderms. Here Hörstadius's "über Heterosperma Seeigelmerogone" stands out. His beautiful and exact work, entailing the finest microtechnique, is well known, and needs no introduction here.

Physiology, embryology, ecology, morphology and systematics all have their share of attention, both in the mollusca and elsewhere. It is, however, impossible to mention them all in so short a space. All are valuable and interesting, and the whole volume is well got up and well illustrated.

(1) Botany for Children

By Lady Elphinstone. Pp. iv+160+12 plates. (London: Burns, Oates and Washbourne, Ltd., 1936.) 3*s*. 6*d*.

(2) The Junior Gardener

By Harriet Price. Edited by Walter P. Wright. Pp. xii+134+4 plates. (London: J. M. Dent and Sons, Ltd., 1936.) 5*s*. net.

THAT the child is indeed father of the man is being made increasingly obvious by the findings of modern psychological research. Any books, therefore, that aim at awakening in the developing child a sincere interest in a human activity so worth-while as the study and cultivation of plants are to be welcomed.

(1) In "Botany for Children" Lady Elphinstone revives a method of exposition very popular in the early part of last century. Jean, Mary and John, three inquiring children, learn about the characters of British plants from the lips of Dame Nature. The idea is, on the whole, well carried out; but the terms order, family, genus and species are used exceedingly loosely throughout the book. There are line block and coloured illustrations, the latter being arranged on a novel plan. The whole plant (including root) is shown against a background of its usual habitat, with a single fruit inset in one corner. On the whole, the paintings are accurate and give a fairly good impression of the plant.

(2) "The Junior Gardener" is written to help boys and girls who are taking up practical gardening for the first time, whether at home or at school. It tells in simple language how to carry out the various basic operations of gardening, and is fully illustrated with diagrams, drawings and coloured plates. The author has had personal experience of the problems of school gardening, and the chapter devoted to that subject should prove one of the most valuable in this well-planned and well-written book. J. S. L. G.

Mercury Arc Rectifier Practice

By F. C. Orchard. Pp. xi+224+23 plates. (London: Chapman and Hall, Ltd., 1935.) 15*s*. net.

DURING recent years there has been an increasing demand for machines and devices which will convert alternating currents into direct currents. Bulk supplies are usually given by alternating currents, but for some supply networks and for traction, direct currents are required. In these circumstances, devices such as machines called rotary converters, or stationary apparatus utilizing a physical property of electrolytes—electric arcs, gas discharge tubes, etc.—are employed. The latter kinds of apparatus are called rectifiers and are of many types utilizing very different physical phenomena.

Most books on rectifiers devote much time to explaining the mathematical and physical theories on which the working of the various kinds of rectifiers is based. To the men who have to instal and operate the glass bulb and steel tank types of mercury arc rectifiers used commercially for service on public supply systems, on railways and for industrial purposes generally, a book that will assist them in their daily work is required, and we think that they will find the book under notice a real help.

Handbuch der Geophysik

Herausgegeben von Prof. Dr. B. Gutenberg. Band 1, Lief. 3: Breitenschwankungen, von Prof. Walter D. Lambert; Theorie des irdischen Schwerefeldes, von Prof. E. A. Ansel. Pp. iv+501–730. Lief. 4 (Schluss des Bandes): Beobachtung der Schwerkraft; Die Lotabweichungen; Das Problem der Isostasie. Von Prof. Dr. W. Heiskanen. Pp. 731–970+xv. (Berlin: Gebrüder Borntraeger, 1934, 1936.) 31 gold marks each part.

DR. LAMBERT's account of the variation of latitude is good, but a little too brief. Ansel on the theory of the gravitational field is mostly excellent, and so is Heiskanen on observations of gravity, pendulum deflections, and isostasy. Ansel claims to have detected an algebraical error in Darwin's theory of the figure of the earth, which affects the sign of the term in $\sin^2 2\varphi$, and he is apparently supported by Heiskanen. Here I think Darwin is right. One misses an account of the important work of de Sitter and his colleagues. Such omissions, however, are very few. These parts complete vol. 1 of the "Handbuch"; vols. 2 and 4 are already complete. H. J.

Lessons in Elementary Analysis

By Dr. G. S. Mahajani. Second edition. Pp. xii+264. (Poona: Aryabhushan Press, 1934.) n.p.

THIS book, first published in 1929, is designed to cover the analysis required for the bachelor's degree in most of the Indian universities. It deals mainly with the theory of number, in which there is an interesting examination of Dedekind's method; the theory of limits; infinitesimals and continuity; the mean value, Maclaurin's and Taylor's theorems; Riemann integration; infinite integrals, uniform convergence and Fourier series. There is also a useful addendum on beta and gamma functions, power series, the application of Taylor's theorem to functions of several variables, Euler's theorems on homogeneous functions and Young's theorem on implicit functions.

Each chapter contains a set of exercises for the student, and the text is thoroughly well written, the exposition of difficult points being exceptionally clear. The book should serve admirably the purpose for which it was written.

Praktische Übungen zur Vererbungslehre:

für Studierende, Ärzte und Lehrer. Von Prof. Dr. Günther Just. Zweite vermehrte und verbesserte Auflage. Teil 1: Allgemeine Vererbungslehre. Pp. vi+137. (Berlin: Julius Springer, 1935.) 6.90 gold marks.

ALTHOUGH small, this compactly produced book contains a well-arranged exposition of methods in genetics. While mainly devoted to statistical methods, it includes measuring instruments, the technique of breeding *Drosophila*, and different types of mouse cages. The statistics deal with continuous and discontinuous variation, the binomial curve, correlation tables, back-crossing, sex-linked characters, the testing of Mendelian ratios, the χ^2 test and other methods commonly used by geneticists.

Trends in Modern Physics*

By Prof. Allan Ferguson

THE world-picture of the older generation was, as we look back on it to-day, extraordinarily simple. It is, or has been, the fashion to describe nineteenth-century science as materialistic. There certainly was Buchner, and there was Tyndall's Belfast address. But *Dr. Stoffkraft* had neither a long reign nor an influential following, and we shall be nearer to the truth if we look upon Victorian science as showing a simple realism—the realism of the man in the street—not wholly unrelated to that simple realism of to-day which sees in an alpha-ray track evidence for the existence of an atom, of the same order as that furnished by a diffraction photograph (or, for that matter, by our own eyes) for the existence of a star.

What we have learned to call the classic outlook was based on those notions of velocity, acceleration, momentum and force which were first formed into an ordered scheme by the genius of Newton—a scheme which sufficed to describe, succinctly and clearly, the series of perceptions involved in such phenomena as the motion of a pendulum, a billiard ball, a railway carriage, and (with certain reservations concerning fine points) the complex motions of the bodies of the solar system. The physical science of the eighteenth and nineteenth centuries was occupied in extending and clarifying these concepts, although eighteenth-century science in England was hampered by an excessive devotion to the memory of Newton, which committed the English mathematicians to the fluxional notation. It required the formation of a society at Cambridge "to inculcate the principles of pure *d*-ism, and to rescue the University from its *dot*-age", before the British physical school could rival the advances of their Continental brethren.

As we have said, the attitude of the physicist to the fundamentals of his science was, in general, naïvely realistic. Mass was quantity of matter, and matter itself was defined as "that which can be acted upon by, or can exert force", or alternatively "that which may have energy communicated to it from other matter". *Obscurum per obscurius*, with a vengeance!

Quantitatively, mass was defined, following Newton, as the product of volume and density; and even Thomson and Tait are roused to a hint (without attempting to resolve the difficulty) that such a process results in a circular argument, inasmuch as we have no other way of defining density than as the ratio of mass to volume.

Early in the nineteenth century, discoveries, mainly in the realm of chemistry, gave fresh interest to atomic doctrines, and the simple concept of the billiard-ball atom proved to be brilliantly successful in explaining old happenings and in predicting new ones. It is not immediately obvious that an extrapolation of those laws which describe the motions of bodies of the dimensions of a locomotive or a planet down to bodies of the indescribably minute dimensions given to an atom or molecule is likely to be successful in subsuming certain perceptual events; the extraordinary thing is, not that such an extrapolation should break down somewhere, but that it should have any validity at all; and the triumphs to be put to the credit of the hypothesis are sufficiently remarkable, as any treatise on the kinetic theory of gases will testify.

No survey of the physical science of the last generation would be complete did it contain no reference to radiation and to the nineteenth-century concept of the mechanism by which radiation is conveyed. Despite the difficulty of framing a theory of the ether which should satisfy dynamical laws—"Why should it?" we might remark incidentally to-day—the concept of an ether of space was so brilliantly successful in correlating and predicting so many and so diverse phenomena—we need but instance that bending of light round corners which we call diffraction, that alternate heaping up and destruction of light which we term interference, and that remarkable refraction of a ray of light by certain crystals as a cone of rays—as to draw from Lord Kelvin the downright statement, "This thing we call the luminiferous ether . . . is the only substance we are confident of in dynamics. One thing we are sure of, and that is the reality and substantiality of the luminiferous ether". Strange reading, to-day; and reading which might well introduce a note of hesitation into some of the confident declarations of present-day realities.

Molar mechanics, the billiard-ball atom, the ether: the nineteenth century had built on these apparently stable foundations an immense structure of ordered knowledge. The closing years of the century were fated to show cracks in the superstructure and weaknesses in the foundations.

---

* From the presidential address to Section A (Mathematical and Physical Sciences) of the British Association, delivered at Blackpool on September 11.

The facts of radioactivity and the discovery of the electron showed that the concept of the atom must increase in complexity were it to remain competent to subsume the additional perceptual facts ; and the experimental study of the radiation from a hot body revealed a state of affairs inexplicable on the lines of classical theory, as did the investigation of the phenomenon known as the photo-electric effect.

It is unnecessary to tell in detail the story of the introduction into physical science of the revolutionary notion of quantization ; of the concept of the nuclear atom ; of the rationalization of the facts of spectroscopy by the application of quantum ideas to the nuclear atom ; of the breakdown of this latter concept when applied to atoms more complex than a single electron system ; of the building up on quasi-empirical lines of a vector model of the atom which should be capable of providing an explanation for the complex facts of spectroscopy ; of the further emphasis placed on that dualism of outlook which appeared so early in twentieth-century physics by the discovery of the Compton effect and by the investigation of electron-diffraction and of molecular-ray diffraction ; and of the impending disappearance of that dualism under the impact of the analysis of the last decade.

Atomum expellas furca—and there is something appropriate in giving such a designation to a Ψ-function—*tamen usque recurret.* If two of the high lights of twentieth-century physics are provided by the introduction of quantum ideas and by the identification of mass and energy, a third is provided by that remarkable rain of sub-atomic particles which has increased incredibly in intensity since the discovery of the electron more than a generation ago, and has provided opportunities for nucleus-building of which theorists have not been slow to make use.

By nothing has the world-picture of to-day been so transformed from that of a generation—nay of a decade—ago than by the introduction of the uncertainty principle and by its effect on our notions of causality.

It can be shown that of two conjugate quantities —time and energy, or position (x) and momentum (p)—the product of their uncertainties of determination can never be less than the quantum h. Thus an increase in the accuracy of the determination of one quantity necessitates a corresponding decrease in the accuracy of the conjugate quantity, and in particular the exact determination of one quantity leaves the other completely undetermined. An attempt to determine the position of a particle involves its illumination by light of suitable wave-length, and decrease of the wave-length in order to improve the definition of its position involves an increase in the magnitude of the recoil due to the Compton scattering process.

Following a suggestion of Dr. H. T. Flint, let us fix our attention on the quantities position and momentum, and consider a co-ordinate system in which momentum (p) is plotted along one axis and position (x) along the other. The co-ordinate space gives us the possible simultaneous values of x and p. Suppose this space divided into rectangles each of area h. Then the uncertainty principle, which asserts that the product ($\delta x \delta p$) of the uncertainties of the determination of position and momentum can never be less than h, may be illustrated by resuscitating Maxwell's demon and permitting him to push a point about at will within any one of the rectangles. The movement of the point, that is, the corresponding changes of position and momentum, will not be detected, for they do not correspond to any detectable change in the world of sense.

Unfortunately the word 'indeterminism', which has other connotations, has become associated with the statement of the principle. Many will recollect Clerk Maxwell's immortal account of the proceedings of Section A at the Belfast meeting of the British Association sixty-two years ago, when Mr. Herbert Spencer regretted "that so many members of the Section were in the habit of employing the word Force in a sense too limited and definite to be of any use in a complete theory of evolution. He had himself always been careful to preserve that largeness of meaning which was too often lost sight of in elementary works. This was best done by using the word sometimes in one sense and sometimes in another, and in this way he trusted he had made the word occupy a sufficiently large field of thought".

Is it heresy to suggest that some of us who have sung canticles in praise of indeterminism and the disappearance of causality have given a similar generousness of meaning to these words ?

Similar considerations apply to the term *observable*, which has suffered a sea-change in transference from its ordinary usage in the realms of perception. There is quite as much complicated physical theory lying between the perceptually observable marks on a photographic plate and the inferred frequencies, as there is between similar perceptual observables and the non-observable electron orbit or state which was inferred in order to subsume the perceptual facts. A similar generosity of treatment is accorded to the term *observe* when it is applied to the conceptual experiment for the determination of the position of a particle such as an electron.

Which brings us round to the starting-point of this discourse. Many of us who desire to proceed with our measurements untrammelled by these philosophic doubts have asked if there is not some canon by which the plain man could test his everyday beliefs. I suggest that a starting-point at least to this end is provided by a study of Karl Pearson's work, and that, with certain reservations and additions to the method discussed in the "Grammar of Science", we may develop a canon which will serve as a guide through the jungle of additional perceptual facts which the physical science of the twentieth century has added to that of its predecessors.

Those who discuss the doctrine of causality do so with little reference to the attitude taken by the philosophers, and it may not be without interest—it certainly has some bearing on present-day thought—to consider the development of the notion of cause since the time of Newton. The views of Locke, Newton's elder contemporary, are clear and simple. He remarks: "Thus, finding that in that substance which we call *wax*, fluidity, which is a simple idea that was not in it before, is constantly produced by the application of a certain degree of heat, we call the simple idea of heat in relation to fluidity in wax the *cause* of it, and *fluidity* the effect. . . . So that whatever is considered by us to conduce or operate to the producing any particular simple idea, whether substance or mode, which did not before exist, hath thereby in our minds the relation of a cause and so is denominated by us".

Newton, dominated as he was by the principle of causality and ever searching for a clear physical picture of the results of his investigations, was capable of a philosophic breadth of view which needs surprisingly little modification to-day. He makes, for example, a physical picture of matter as formed in "solid, massy, hard, impenetrable, moveable particles", and assumes that they have not only a *Vis Inertiæ*, but are moved by certain active principles, such as gravity. These principles are to be considered "not as occult qualities . . . but as general Laws of Nature . . . their Truth appearing to us by Phænomena. . . . To tell us that every Species of Things is endowed with an occult specifick Quality by which it acts and produces manifest effects, is to tell us nothing; but to derive two or three Principles of Motion from Phænomena and afterwards to tell us how the Properties and Actions of all corporeal Things follow from these manifest Principles would be a very great step in Philosophy, though the Causes of those Principles were not yet discovered; and therefore I scruple not to propose the Principles of Motion above mentioned, they being of very general extent, and leave their Causes to be found out". Evidently Newton takes the view that we have made an important step forward when we have subsumed a number of perceptual facts under a general formula.

It is to Hume, though he may owe something to Glanvil and other predecessors, that we are indebted for a clearly ordered statement of the experientialist doctrine of causation. The generalization, for example, that the earth attracts a stone is explained as a generalization from thousands of observations. "Adam . . . could not have inferred from the fluidity and transparency of water that it would suffocate him, or from the light and warmth of fire that it would consume him. No object ever discovers by the qualities which appear to the senses, either the causes which produced it or the effects which will arise from it; nor can our reason, unassisted by experience, ever draw any inference concerning real existence and matter of fact".

Mill further developed the experientialist doctrine in the statement that the law of causation "is but the familiar truth that invariability of succession is found by observation to obtain between every fact in nature and some other fact which has preceded it, independently of all considerations respecting the ultimate mode of production of phenomena, and of every other question regarding the nature of things in themselves". To the doctrine of succession in this simple form the objection has been urged that day may be regarded as the cause of night and conversely. Mill meets this objection by pointing out that invariable sequence does not necessarily involve causation. To involve causation the sequence must not only be invariable but also *unconditional*. The day-night sequence is conditioned by the sun and so does not conform to this test. "We may define, therefore, the cause of a phenomenon to be the antecedent, or the concurrence of antecedents, on which it is invariably and unconditionally consequent".

It is difficult to sum up Pearson's attitude to the problem of causality and to the general problem in a few sentences. Perhaps Kirchhoff's dictum concerning mechanics: "Die Mechanik ist die Wissenschaft von der Bewegung; als ihre Aufgabe bezeichnen wir: die in der Natur vor sich gehenden Bewegung *vollständig* und *auf die einfachste Weise* zu beschrieben", touches very nearly the root of the matter.

We live, in fact, amid a mass of perceptions; and it is the business of physical science to correlate, in as simple a fashion as may be, a certain section of these facts. To this end the physicist devises a *conceptual* world of atoms and molecules, from which he builds up a system—a world-picture—of molar masses whose motions correspond to the routine of our sense impressions. Given a frame of reference, we can formulate laws of motion for two isolated particles in a conceptual world which may be summed up in the statement that whatever be the positions and velocities of the particles the ratio of their accelerations is always constant; this ratio is defined as the inverse mass-ratio of the particles; and in virtue of this we have the relation that—

Mass of A × acceleration of A = mass of B × acceleration of B.

We give the name *force* to this product, and hence obtain the law that action and reaction are equal and opposite. On the basis of such definitions we can build up a structure of bodies in the conceptual world the motions of which, predictable under the descriptive laws formulated, will agree with the routine of our world of sense perceptions. We have, in fact, *explained* certain phenomena.

There is, of course, no logical reason why, in this description, we should stop short at the second derivative—acceleration—or go forward to it for that matter. We are concerned to find the simplest and most consistent explanation, and this procedure provides it. Indeed something of æsthetics may also influence our choice.

The atom, whatever its complexity, whether the concept remains sharp as that of a billiard ball or a miniature solar system, or whether its outlines disappear in a probability-smear, remains a *concept* outside the realm of perceptual happenings which it is the business of the concept to correlate. It may or may not emerge into the perceptual world; unless and until it does, discussion of its reality is beside the mark.

Planck, defining the causal condition in the statement that an event is causally conditioned if it can be predicted with certainty, goes on to remark that the possibility of making a correct prediction has not to be interpreted as anything more than a criterion for a causal connexion, but that the two do not mean one and the same thing. Day is not the cause of night, although we may be able to predict the advent of night in the daytime. Day is, therefore, a causally conditioned event.

Taking the definition as it stands, we find that in the realm of quantitative physical events we cannot, purely as a matter of measurement, predict *accurately* in advance any one physical event—this, without introducing quantum considerations. Prof. Planck escapes from the indeterminist position by transferring the definition to a conceptual world in which exact measurements may be made and events correctly predicted. He assumes, in fact, in its broad outlines, the thesis of the "Grammar of Science". He thus retains the principle of causality, as defined above, in the happenings of the conceptual world, remarking that the relation between events in the perceptual and conceptual worlds is subject to a slight inaccuracy.

The introduction of Heisenberg's uncertainty principle necessitates a corresponding process in dealing with perceptual problems from the point of view of quantum physics. A conceptual world of quantum physics is framed in which a strict determinism reigns. True, the world has not so many points of resemblance to the perceptual world as had the older schemes—billiard-ball and solar-system atoms have disappeared, and the wave-function, which does not refer to ordinary space, is not so easily interpreted in terms of the world of sense. But the philosophical problem of the transfer is the same.

Whatever the form of the picture, the hard-pressed physicist of to-day remains on firm ground if he refuses to confuse the concept—the world-picture—with the percept; if, making this distinction, he studies the question of the reality underlying phenomena as philosopher rather than as physicist; if he is as ready to discard outworn models as ever Maxwell was.

There is no finality in these matters, and solutions of these difficulties are solutions for a day; but it is interesting and heartening to know that Planck, the initiator of the movement which has revolutionized physical thought, has, a generation later, pointed a way to a resolution of the fundamental doubts and difficulties which his genius has raised.

. . . . .

Of recent years the British Association has concerned itself more and more with a study of the repercussions of the advancement of science on the fabric of our society. Never in the history of mankind have more powerful weapons for good and for evil been placed in the hands of the community as a direct result of the growth of scientific knowledge; and never has it been more necessary for the scientist to develop some awareness of the effects of his activities on the well-being of that community of which he himself is a responsible member.

We are most of us ready enough to discuss the "Impact of Science on Society", so long as we restrict ourselves to an enumeration of the benefits which science has bestowed upon mankind; and on occasion we may make a rather snobbish distinction between cultural and vocational values. But we have to remember actively that there are dysgenic applications of scientific knowledge, and if the scientist claims, as he rightly does, that place in the counsels of the nation which the importance of his work warrants, he must cease his worship of what Prof. L. Hogben calls the "Idol of Purity", must be prepared to discuss all the social implications of his work and to educate himself, as well as his less fortunate brethren trained in the humanity schools, in a knowledge of these implications.

The British Association is peculiarly fitted to develop and discuss such knowledge ; in Section A we have made a beginning, but we have as yet touched on but few of these interactions. Our steps are naturally at first a little halting, but with increasing knowledge there will come, I trust, an increased power in elucidating those complex and difficult social problems which the astonishing developments of the last generation have forced on the civilized world.

Science and the Poultry Industry

THE claim of the poultry industry to rank as the third largest branch of British agriculture, when judged by the value of its output, will scarcely be questioned by the visitor to Blackpool for the recent meetings of the British Association. Over the greater part of the County Palatine through which he travelled, the fortunes of farming are based largely upon cows, poultry and pigs, mainly in the order given, whilst the more immediate hinterland of Blackpool is thickly studded with specialist poultry farms. On arrival he would not have been surprised, therefore, to find from his programme that two sections of the Association had thought it worth while to devote a whole afternoon to a joint session for the discussion of problems of the poultry industry, and that further, provision had been made for an external lecture at a rural centre, Poulton-le-Fylde, on the same subject.

For this latter purpose no choice could have been happier than that of Mr. Percy A. Francis, the Poultry Commissioner of the Ministry of Agriculture, who combines unique opportunities of observing the progress of the application of the various sciences to the practice of poultry husbandry with a flair for the exposition in simple terms of his observations that is widely appreciated throughout the industry.

Mr. Francis' survey of the applications of science to the poultry industry necessarily covered a wide field, since in no branch of livestock husbandry are the needs of scientific guidance so varied as in the poultry industry of to-day, with its systems ranging between the two extremes of the open pasture and the intensive 'battery'. At every stage—mating, incubation, rearing, laying, fattening—and in every phase of management—feeding, housing, hygiene, disease control—the keys to success have scientific wards, and the ultimate result is largely affected by the degree to which fundamental scientific postulates have been respected or ignored.

In view of the popular conception of the farmer as being too slowly responsive to the aid of science, it will come as a surprise to many to learn that Mr. Francis is inclined to suggest that some part of the present troubles of the industry on its production side may be traceable to over-haste and ill-informed zeal on the part of the poultry farmer in the incorporation of scientific discoveries into his practice. That there is substance in this suggestion can scarcely be doubted. In the application of new ideas to the development and management of the animal, an immediate improvement can only be accepted as desirable if it is not offset by an ultimate disadvantage of more serious import. Where the animal is used as a breeder, this disadvantage may not be evident until the third or fourth generation or even later. With an animal that grows and multiplies slowly, like the bovine or the human being, the deterioration may indeed cover so long a period of years as to escape detection unless the most careful and prolonged records are kept ; but with a species that grows and multiplies so rapidly as the fowl, the penalty is likely to fall more swiftly, and moreover to be far more widespread in its incidence.

For any errors committed by the poultryman in this respect, the scientific investigator must accept a share of blame, in that all too often he has not made sufficiently clear to the layman that his new discovery, though the latest, is almost certainly not the last word on the subject, and therefore does not justify the poultryman in dissolving completely the partnership with Nature, which hitherto has helped to make good the defects of the combined knowledge of farmer and scientific adviser.

Nowhere has the great advance in our knowledge of animal nutrition furnished by the discovery of vitamins and the study of mineral requirements been more strikingly exemplified than on the poultry farm ; nowhere has the incompleteness of our extended knowledge been more clearly demonstrated.

The major problem with which the industry on its production side is now faced is that of the rising rate of mortality amongst adult stock. There can be little doubt that this is in part only a manifestation of the general tendency for increasing loss to occur from diseases and other causes when a population is allowed to grow very rapidly without the coincident development of an efficient 'public health' service. The major causes must probably, however, be looked for in other directions, since the great increase in the poultry population between 1918 and 1928 was not accompanied by any serious rise of mortality. Some are inclined to look upon the present troubles of the industry as the harvest of seed sown in that earlier boom period, when possibly the industry expanded faster than its capacity to supply itself with sound breeding stock ; others place the major blame upon excessive resort to 'intensive' methods—too much science ! Still others find a partial explanation in the all too easy dissemination of stock from uncontrolled breeding centres. Wherever the cause may lie, be it in breeding, incubation, management, disease control, or any other part of the field of the poultryman's activities, the need for a combined attack upon the problem is now clamant. Practice alone is unlikely to prove capable of finding a solution ; to the scientific investigator, a vast field of service is open in which the rewards, both to the individual and to the nation, are great and certain. C. C.

Obituary

Prof. R. C. J. Howland

RAYMOND CLARENCE JAMES HOWLAND was born in Fulham on June 5, 1896, and was educated at Latymer Upper School, Hammersmith (1907–15). In December 1914 he won an open scholarship at Emmanuel College, Cambridge, and went into residence in October 1915. After two terms, an attempt to join the O.T.C. having failed on account of defective eyesight, he nevertheless succeeded in enlisting as a gunner in the R.G.A. in March 1916, went to France and served through the rest of the War, returning to Cambridge at the beginning of the Easter term 1919. Although he obtained a first class in Part I of the Mathematical Tripos and was a wrangler in 1920, the handicap due to the interruption of his studies by the War prevented him from taking Schedule B, and debarred him from opportunities which should normally have been open to one of his mathematical ability. In consequence, he went down from Cambridge after taking his degree in 1920 and spent a year in school-teaching at Berkhamsted.

While in Cambridge, however, Howland had prepared for the London external degree, and took his B.Sc. in 1921 with first class honours ; this was followed later by the M.Sc. (1922) and by the D.Sc. (1930).

Fortunately, the openings not available to him in Cambridge were found elsewhere, and, in September 1921, Howland was appointed lecturer at the City and Guilds Engineering College, where he remained for two years. It was there, working under the influence of Prof. H. Levy, that he completed his first piece of mathematical research on "Vortex Motion behind a Circular Cylinder", published in the *Journal of the Royal Aeronautical Society* (1925). His first work to be actually published, however, was a paper on "Transverse Oscillations in Girders" (Institution of Civil Engineers, 1924).

By this time, Howland had obtained (October 1923) a senior lectureship at University College, London, where, although more specially in charge of the teaching to engineering students, he shared in the general work of the Mathematics Department. That he found the atmosphere congenial is shown by the fact that, during the eight years he was at University College, he produced no less than eleven papers, some of outstanding importance.

Howland's scientific interests were almost exclusively directed to problems of classical mechanics, particularly hydrodynamics and elasticity, with engineering applications. Several of his papers deal with rotating shafts, a subject to which he made serious contributions. Here and there we find papers, for example, on determinantal equations and on harmonic and biharmonic periodic functions, which prove that his abilities would have found scope equally on the side of pure mathematics. The work for which he will be best remembered, however, is his solution for an elastic strip of finite width with one or more circular holes, to which he devoted a series of papers in the *Transactions* and *Proceedings of the Royal Society*, either alone or with co-workers. His last paper on this subject was published in 1935, but the fundamental step, namely, the discovery that he could evaluate the troublesome double integrals occurring in the investigation by changing the order of integration, will be found in the first paper of the set (*Proc. Roy. Soc.*, A, **124** ; 1929).

Shortly after publishing this, Howland was appointed (October 1931) to the chair of mathematics at University College, Southampton. There he threw himself into the work with his accustomed energy. He had the rare gift of inspiring others to do research, and when he died he had developed a flourishing mathematical school, which he hoped would deal successfully with the problems of local industries, such as shipbuilding and aircraft construction. He was taken ill somewhat suddenly, while travelling in Wales, and died on August 16 of this year. His premature death at the age of forty years not only is a cruel blow to his family and his many friends, but also deprives modern engineering of one of its most able and sympathetic mathematical helpers, one who would undoubtedly have made further notable advances in the science of applied mechanics.

As a man, Howland was of a modest and retiring disposition, and it was almost impossible to get him to talk about himself. Behind his reserve, however, lay many wide and human sympathies. In his undergraduate days he was constantly writing both prose and verse, and the choice between literature and mathematics hung for some time in the balance. He was a keen musician and took a full share in musical activities at Southampton. The subjects of various addresses he gave to more popular audiences, on "The Mystery of Number", "Mathematical Wit and Humour" and "Greek Mathematics" are enough to indicate the catholicity of his interests, even in the mathematical field. He married, on November 10, 1923, Lucy Jane Bullock, and his happy life at home contributed in no small measure to the full development of his scientific powers. L. N. G. F.

Prof. Alexander Larmor

THE death, on October 10, of Alexander Larmor, emeritus professor of natural philosophy at Magee College, Londonderry, has removed one who rendered very valuable services to scientific education in Northern Ireland. His published work, though important, gives a very inadequate idea of his powers of mind and his wide knowledge; his friends and correspondents know that, if he wrote comparatively little, he thought deeply on the subjects which interested him.

Larmor's first paper, published in the *Quarterly Journal of Mathematics* in 1886, was on the geometrical theory of perspective, and his last, which appeared in 1933, treated of the FitzGerald contraction. These titles indicate the early and the later interests of a man who, at the beginning, studied under Purser and Everett at Queen's College, Belfast, and who took both the Mathematical and the Natural Science Tripos before becoming fellow of Clare College, Cambridge. He began by working at pure geometry; a taste for this subject and great expertness in it were, in his day, imparted to mathematically gifted boys in Irish schools. His most important geometrical paper, contributed to the London Mathematical Society in 1892, was on the contacts of systems of circles. In later years he became absorbed in the fundamental problems of space and time; he kept himself abreast of recent speculations in this region, and brought to them a mind philosophical and acutely critical.

During his tenure of his chair at Londonderry, Larmor gave himself with his whole heart to the work of teaching and administration, and won the regard and gratitude of pupils and colleagues alike. His lectures were admirable, his sympathetic interest in his students unfailing. He took his full share in the politics of the college in a critical period in its history, and helped greatly in the solution of its difficulties.

Larmor was quiet and reserved in manner, but his obvious sincerity and friendliness exercised a strong attraction upon those who had the privilege of knowing him. To younger men, in particular, he was continually showing kindness, and very many will feel for him life-long affection and gratitude.

W. B. M.

Prof. L. M. Ugolini

WE regret to record the death of Prof. Luigi M. Ugolini, the well-known Italian archæologist, which took place at Bologna recently at the age of forty years.

Luigi Ugolini was born at Bertinoro in Romagna and served in the Alpini during the Great War, being wounded and gaining a bronze medal for valour. After the War he travelled extensively in Europe, Egypt, Roman Africa and the East in the pursuit of his archæological studies. His best known work was connected with the excavation of archæological sites at Fernice and Butrinto in Albania, where he brought to light a number of Greek and Roman antiquities. He had already published three volumes on his researches, and other material was in course of preparation. He was also the author of a work on the prehistoric antiquities of Malta. Recently he had been appointed to a chair in the University of Rome.

Prof. Victor Grignard

PROF. CH. COURTOT, of Nancy, has given an account (*Bull. Soc. Chim.*, **3**, 1433; 1936) of the life and work of Prof. Grignard, Nobel Laureate in 1912, who was best known for his researches on the use of organo-magnesium compounds in synthetic chemistry. Born at Cherbourg in 1871, professor of organic chemistry at Nancy in 1910 and of general chemistry at Lyons in 1919, Grignard carried out a large number of investigations in organic chemistry: Prof. Courtot gives the titles of 163 publications by him and his pupils. During the Great War, he rendered valuable services and was made a member of the Legion of Honour. He was elected an honorary fellow of the Chemical Society in 1920. Shortly before his death on December 13, 1935, Grignard commenced a large treatise on organic chemistry, the first two volumes of which appeared during his lifetime.

We regret to announce the following deaths:

Mr. W. J. Blenheim, American traffic manager of the Western Union Cable system, a pioneer of radio research, on October 29, aged fifty-eight years.

Prof. A. Bömer, emeritus professor of applied chemistry in the University of Münster, and editor of the *Zeitschrift für Untersuchung der Lebensmittel*, aged sixty-nine years.

Prof. T. M. Lowry, C.B.E., F.R.S., professor of physical chemistry in the University of Cambridge, on November 2, aged sixty-two years.

Dr. Sheffield H. M. Neave, known for his work in 1906–7 on sleeping sickness, on October 24, aged eighty-three years.

News and Views

The Nobel Laureates in Medicine

THE Nobel prize for medicine for 1936 is divided between Sir Henry Dale and Prof. Otto Loewi. Sir Henry Dale must have had more influence on medical research than anyone else alive to-day. In the years before the Great War, the Wellcome Physiological Research Laboratories, with him as director, were making discoveries such as had never before been made by a laboratory connected with a pharmaceutical firm. More recently, the National Institute for Medical Research has grown under his guidance until it has become the leading centre for medical research in Great Britain, if not in the world. Sir Henry has been largely responsible for the success of the Commission of the League of Nations on Biological Standards, and it is because of him that a large proportion of the International Biological Standard Preparations are kept in Great Britain. He has been secretary of the Royal Society, and a member of the General Medical Council and numerous committees, but his influence has extended over a much wider field than that covered by these public activities. For many years, he has been consulted, with affectionate respect, by people from all over the world, on questions ranging from general policy to experimental detail. Among all these activities, he has found time to make important discoveries in many fields. He has shown an unusual prescience in working out problems which must have seemed trivial at the time, but have since turned out to be fundamental. Prof. O. Loewi's direct influence has covered a narrower field. Working with simple apparatus, for many years now in Graz, he has shown an uncanny genius for paradoxical discoveries which were not at first believed, but were later confirmed and extended by other, and more elaborate, methods, and formed the basis of one of the most interesting fields of scientific advance. His work has touched many problems, and he is one of the best known and most beloved of German-speaking pharmacologists.

Transmission of Nervous Impulses

THE Nobel prize has been awarded to these two men of science for work on the chemical transmission of nervous impulses. It was known that the effects produced by stimulating sympathetic nerves were also produced by adrenaline, and that the effects of stimulating the vagus were also produced by muscarine and various other drugs. Elliott had hinted, in 1904, at the possibility that sympathetic nerves might produce their effects by actually liberating adrenaline, and Dixon and also Howell had tried to show that some substance was liberated by vagus nerve endings. Dale found that extracts of ergot contained a substance like muscarine, but unstable. This substance turned out to be acetylcholine, and in 1914 Dale, realizing its possible importance in connexion with the vagus, made a detailed study of its effects in the body, in which he showed that it not only reproduced the effects of muscarine, but also those of nicotine. In 1921 Loewi published the first evidence that nerve endings liberate active substances. Under appropriate conditions, the vagus and sympathetic nerves to a frog's heart were shown to liberate two substances, detected by their action on a second heart, and called by Loewi *vagusstoff* and *acceleransstoff*. A dozen papers from Loewi's laboratory answered criticisms of this work and filled in details.

Acetylcholine and Adrenaline

ALL the facts were compatible with the view that the two substances detected in this work were acetylcholine and adrenaline, but Loewi was too cautious to jump to this conclusion. In 1929 Dale and Dudley, working with large-scale apparatus, isolated acetylcholine for the first time from animal tissues, and came to the conclusion that *vagusstoff* could now be definitely identified as acetylcholine. New evidence has justified this conclusion. The pharmacological methods for identifying small quantities of acetylcholine were improved in Dale's laboratory until it was possible to distinguish acetylcholine from such nearly related substances as propionylcholine, and, with these improved methods, it was shown that a substance which could be definitely identified as acetylcholine was liberated, not only by nerves with muscarine-actions, but also by nerves with nicotine-actions. This year, Loewi, working with a method developed in Dale's laboratory, has obtained evidence which enabled him to identify *acceleransstoff* as adrenaline. Though many have worked in this field, these two men have thus obtained all the vital evidence for the modern view that most, if not all, mammalian motor nerves produce their effects by the local liberation of either acetylcholine or adrenaline.

Dr. W. T. Calman, C.B., F.R.S.

THE retirement, at the end of this year, of Dr. W. T. Calman from the keepership of zoology in the British Museum (Natural History) will deprive the Museum and its visitors of the official services of a distinguished carcinologist. Dr. Calman went to the Museum in 1904 from Dundee, where he had graduated and had been assistant lecturer and demonstrator in zoology in the University College. In 1921, he was appointed assistant keeper of zoology at the Museum, and it was in that year that he was elected a fellow of the Royal Society. In 1927, he succeeded Dr. Tate Regan in the keepership. In 1930, he was president of Section D (Zoology) of the British Association, and he is now president of the Linnean Society of London. Dr. Calman's services to carcinology are well known to all zoologists. His morphological studies are at once shrewd and sound, and the same qualities of insight and judgment are combined with accuracy in his extensive contributions to the systematics of the Crustacea. His volume on this class in Lankester's "Treatise on Zoology" reveals the width of his erudition and is still indispensable to all students of the Crustacea. Dr. Calman's services to zoology have, of course, not been limited to the group in which he has specialized. His address to Section D revealed his interest in the contribution of taxonomy to the greatest zoological problems, and his work at the Museum has shown grasp of and sympathy with the study of all parts of the animal kingdom. In retiring, Dr. Calman takes with him the best wishes of all those to whom his friendly help has been extended, and their hope for much further contribution from him to his science. Mr. M. A. C. Hinton, assistant keeper of zoology in the Museum, will succeed Dr. Calman.

Opening of B.B.C. Television Service

ON Monday, November 2, the high definition television service of the British Broadcasting Corporation was officially inaugurated by Major the Right Hon. G. C. Tryon, H.M. Postmaster-General. This event marks the end of the first experimental period of the television service from the Alexandra Palace, which began during the radio exhibition at Olympia last August. During this experimental period considerable progress was made in the technique of transmitting both direct scenes and cinematograph films, using alternately the Baird and the Marconi-E.M.I. systems of transmission. During the opening ceremony, the Postmaster-General and others had to address themselves not only to listeners but also to viewers within a radius of some 25 miles. As reported in *The Times*, Mr. R. C. Norman, chairman of the B.B.C., was the first to use the word 'viewers' in its new meaning on this occasion. He recalled the fact that almost exactly fourteen years ago, the British Broadcasting Company, as it was then called, transmitted its first broadcasting programme from Marconi House. Following the formal speeches, Monday's programme included a variety item and an excerpt from British Movietone news. As Mr. Norman pointed out, this simple ceremony and programme may possibly seem rather primitive a few years hence to those who are able to recall it; at the present time, however, there is cause for satisfaction on the part of those responsible for the development of this new technique in radio broadcasting.

The Steam Locomotive

AT a meeting of the Institution of Mechanical Engineers on October 23, Sir H. Nigel Gresley was installed as president and delivered an address in which he took, as his main theme, the recent developments in steam locomotives. Forty years ago, the late Mr. Samuel Johnson, in the same position, gave a comprehensive address on the mechanical equipment of British railways, and Sir Nigel pointed out that at that time there were no British locomotives weighing, with tender, 100 tons, no engine with a higher steam pressure than 175 lb. per sq. in., none with a grate area exceeding 27 sq. ft. and no express engine with a higher tractive effort than 19,400 lb. To-day, weights of 165 tons, steam pressures of 250 lb. per sq. in., grate areas of 50 sq. ft. and tractive efforts of more than 40,000 lb. have been attained in Great Britain. In these forty years, the power of British locomotives has increased by a hundred per cent, and the remarkable fact is that these increases have been effected within the limits of the standard track and the even more restrictive limits of the British loading gauge. On American and Continental railways having the same 4 ft. 8½ in. track, locomotives can be built so much higher and wider that engines of double the weight and power of the most modern English engines are quite common. To show the present relative position of steam, Diesel and electric methods of propulsion, numerous figures were given of locomotives and their performances in service, in particular those relating to the *Flying Hamburger*. After prolonged trials, this train was put into operation between Hamburg and Berlin in May 1933. It consists of two articulated coaches on three bogies, is driven by two Maybach 410 h.p. Diesel engines directly coupled to electric generators, and does the journey at an average speed of 77·4 m.p.h. Its smooth running over long distances at a speed of 100 m.p.h. suggested an inquiry as to the possibility of experimenting with extra high speed travel on the London and North Eastern Railway in Great Britain.

THE curves, gradients and speed restrictions on the 268-mile line from King's Cross to Newcastle constitute a more difficult problem than that of the Berlin-Hamburg route, and the makers of the Diesel-electric train estimated that the time required would be 4 hours 15½ min. on the down journey and 4 hours 17 min. up. On the other hand, it was ascertained that a steam locomotive of the "Pacific" type could accomplish it in four hours, and so it was that *The Silver Jubilee* train came to be designed. The engine was made sufficiently powerful to maintain a good speed on the up gradients, for the saving of time in increasing speed from 60 to 90 m.p.h. on a downhill run of 15 miles is only 5 minutes, whereas by maintaining 60 m.p.h. instead of dropping to 30 on the uphill run, 15 minutes are gained. This locomotive exerts a total of 1,750 h.p. when taking a rising gradient of 1 in 200 at 80 m.p.h. It was also mentioned that scale models of the stream-lined engine of *The Silver Jubilee* and of the ordinary "Pacific" type have been under test at the National Physical Laboratory to determine the head-on wind resistances in each case. The horse-power required to overcome these wind resistances has been found to vary from 56·39 and 97·21 respectively at 60 m.p.h. to 881·48 and 1,520·8 at 120 m.p.h., and a remarkable result indicated by the table of figures given is that, within these limits of speed, the saving of power effected by stream-lining is a practically constant proportion, namely 42·1 per cent.

Development of Transport

Sir Alexander Gibb devoted the main part of his presidential address to the Institution of Civil Engineers, delivered on November 3, to an account of some of the works of civilization for which engineers and engineering—in the widest sense—have been responsible. Dealing first with means of transport, he said that the age of roads has now returned. More than 1,000,000 miles of modern roads serve the Empire; that this is still only the beginning is clear from the fact that in Kenya, out of 10,500 miles, only 723 have a metalled surface, the remainder being earth-roads impassable after heavy rain, and in the 370,000 square miles of Nigeria, more than half the 15,000 miles of road are fair-weather roads only. What is required is road planning on really Imperial lines, and the social and political effects would be tremendous. Railway construction in the Empire dated from the middle of the last century. In 1850 Canada had 66 miles of railway; she has now 43,000 miles. With the railways came the steamship era. While the commercial application of the aeroplane has not yet been developed very far, Sir Alexander mentioned that it was almost wholly by air transport that the New Guinea goldfields and various gold and copper mines in northern Canada were opened up. In New Guinea, all the machinery and parts for two large dredgers and a hydro-electric plant of several thousand horse-power were carried wholly by aeroplane over a range of mountains 5,000 ft. high into the interior, and then assembled and put to work within a year.

Engineers and Empire Development

Engineering, or turning to practical account the discoveries of science, Sir Alexander said, is the foundation of civilization. In his opinion, the opportunities of the future are vastly greater than any that the past offered, but he regards with some anxiety the years to come. The machine sometimes seems to be taking control; inventions and developments succeed one another with bewildering speed, and there seems to be no limit to the possible results of uncontrolled and misapplied ingenuity. Engineering provides directly or indirectly the livelihood of about a seventh of the working population of Great Britain. To-day is an age of ever-increasing specialization, and it has inevitably resulted in engineering being split up into many different categories and groups. If the great problems of the future are to be adequately dealt with, an attempt should be made to co ordinate and unite engineering activities in the broadest sense. The Institution of Civil Engineers is taking steps in this matter, and useful work has already been done in the wider question of co-operation with engineering institutions. Sir Alexander thinks that one broad policy should inspire and guide all classes of engineers; there might then arise a body of engineering opinion so weighty, so sane, that it would prevent waste of energy and misplaced enterprise, and would inevitably command attention in the politics, administration and life of Great Britain and the Empire.

Kincardine-on-Forth Bridge

The Kincardine-on-Forth Bridge which was opened to traffic on October 29 will be a great boon to motorists. Hitherto, traffic from Edinburgh to the north bank of the Forth had to cross either by the ferry at Queensferry or by the bridge at Stirling twenty-five miles to the west. The new road bridge is situated nine miles down stream from Stirling. The bridge is half a mile long, and its most interesting feature is the electrically operated swing span in the centre. This span, which rotates on a central pier, weighs 1,600 tons and has a length of 364 ft.—probably the longest span of this type in the world. It provides two clear openings for shipping each 150 ft. wide. A roadway 30 ft. wide with two 5-ft. footpaths goes over the bridge. The whole of the equipment is controlled from a cabin at the top of the span. The saving in mileage between Edinburgh and Dunfermline by this bridge amounts to 20 miles. The cost of the bridge was £350,000; the consulting engineers are Sir Alexander Gibb and Partners.

The turning gear of the swing span of the new bridge is driven by two fifty horse-power motors, but only about a fifth of the full power is required. The main position indicator on the control desk gives an alignment with an accuracy not greater than a few inches. But an inaccuracy so large as this would prevent the wedges and bolts being shot. To overcome this difficulty, two independent aligning systems have been installed, one employing photo-electric cells and the other using a target sight lighting principle. As the end of the swing span approaches its aligning position, the first photo-cell passes across a beam of light. This causes one of three lamps on the control desk to light up and a bell to give one stroke. As the span continues to move, the photo-cell crosses other light beams giving a total of three distinct light and sound warning signals. When another photo-cell arrives opposite a narrow slot, the middle lamp on the control desk indicates correct alignment.

The Heat Engine in the Seventeenth Century

It is generally known that Newcomen was the first to produce a practical cylinder and piston steam engine, but there is a singular lack of evidence to show where he obtained his ideas. Various statements, some of them quite unsubstantiated, about the matter have been made, but little is known with certainty. No one has examined the subject with greater care than Mr. Rhys Jenkins, who at a meeting of the Newcomen Society on October 21 read a paper entitled "The Heat Engine Idea in the Seventeenth Century". In this he impartially reviewed some of his own previous views and endeavoured to trace how the idea of applying heat for motive power might have been handed on from one projector to another in the course of the period 1612–1712. In turn, he referred to the writings and experiments of de Caus, David Ramsay, the Marquis of Worcester, Morland, Papin and Savery. To Papin certainly appears to belong the honour of producing a vacuum under a piston in a vertical open-top cylinder by the condensation of steam, and it may be Newcomen read a review of a book by Papin contained in the *Philosophical Transactions* of March 1697. Mr. Jenkins placed no credence on the story that Newcomen had been in correspondence with Hooke, as stated by Robison in the third edition of the "Encyclopaedia Britannica", and this story must be omitted from the history of the steam engine, at any rate until documentary evidence is forthcoming.

Domestic Lighting

THE summer school of electrical housecraft recently paid a visit to the Lighting Service Bureau of the Electric Lamp Manufacturers' Association. Mr. W. J. Jones laid stress on the need for adequate light in the home for reading and for carrying out domestic tasks. Practical demonstrations were given to prove his statements. He showed how good lighting helps the eye to see quickly, and hence under favourable conditions a task can be performed with greater accuracy and in less time. When a gramophone turntable with a disk of white cardboard marked by two intersecting lines is made to revolve, its speed seems to increase as the amount of light thrown on the disk is reduced. Actually the speed is kept constant, but so effective is the maximum illumination in reducing the apparent speed of the disk that it is difficult to believe that the speed keeps constant. When the disk is brightly lit, the eye has little difficulty in following the rotation of the lines, whereas when badly lit a confused whirl only is seen. The absorption power of decorations was demonstrated and the importance of using extra light to counteract the effects of a dark colour scheme or of decorations was insisted on. A talking film entitled the "Science of Seeing" has been prepared by the Bureau for loan to schools, etc. During his lecture, Mr. Jones asked his audience to choose the amount of light for the most comfortable seeing conditions in the lecture theatre. This was done by raising and lowering the lighting. Individual members chose illuminations lying between 20 and 75 foot-candles.

Factors affecting Freedom of the Press

FOLLOWING on the broadsheet on the state of the press in Great Britain, issued by Political and Economic Planning in 1935, the Press group of P.E.P. has now issued a further broadcast on the freedom of the press. Besides the various legal factors, such as the law of libel, which restrict publication in the press, there are other equally potent influences which may act in restraint of publication, such as advertizing influence, the private policy of a proprietor, or the pressure of public or semi-public bodies may be exerted in various ways which make it more and more difficult to voice emphatically the grievance of an individual or group against authority and monopoly. While absolute freedom of the press is neither possible nor desirable, there are strong arguments for keeping restrictions and external pressure of every kind to a minimum. Moreover, the selection or rejection of news for a newspaper is still mainly determined not by external influences, however powerful, but by the character and outlook of journalists. Where they are content to follow the line of least resistance, giving prominence to trivialities, and evading or ignoring important subjects and points of view that are unpopular or likely to arouse powerful opposition, the control of the press will in fact be determined by the barriers erected against free discussion, with fatal results. Bad journalism begins by driving out good and may end by causing the imposition of restrictions so severe that good, critical, informed and independent journalism is impossible. On the other hand, independent, courageous journalism creates and commands the admiration of independent and courageous people who are powerful enough to support it and defend it. The fate of the press is bound up with the fate of democracy, and in any type of State the press will have to fight harder to justify its existence against competition and encroachments of many kinds.

Archæology in Indo-China

No little success has been achieved by the first two expeditions of archæological exploration conducted by the Greater Indian Research Committee. This Committee was founded in 1934 under the chairmanship of Sir Francis Younghusband with the object of throwing light by field exploration on Indian cultural and colonial expansion throughout south-eastern Asia. An account of the results obtained up to the present is given by Dr. H. G. Quaritch Wales, the field director, in *Discovery* of November. The first expedition began work at Takuapa on the west coast of peninsular Siam. This has been identified with the Takola Mart of Ptolemy. Here the archæological evidence has demonstrated the existence of a considerable settlement of Siva worshippers of South Indian affinities, which flourished from the fourth to the eighth or ninth centuries of our era, and was frequented by Chinese and Islamic traders. Further, a line of communication with the west coast has been traced to the Bay of Bandon, where excavations have been carried out on the site of the ancient city of Chaiya, apparently the capital of a great Indianized empire. Even more important results were obtained by an expedition to a site in eastern central Siam, where in the remote Pasak valley in the vestiges of a city were discovered relics of the vanished culture of the great Fu-nan Empire, of which this had been an outlying emporium on the trade route to the Menam valley. This culture was overwhelmed and completely destroyed by the rise of the Kmers in the sixth century A.D. Here the most important discovery was that of an Indian brick temple, which is the earliest known example of Indian colonial architecture. Previous to this discovery, all early Indian colonial temples were thought to have been built of wood. Several examples of sculpture were also found of pure Gupta style.

The Earliest Printed Book on the Magnet

THE annotated catalogues of antiquarian booksellers who deal especially in old scientific books always make interesting and instructive reading to the student of the history of science. Sometimes these catalogues form the medium for the first announcement of bibliographical discoveries of importance. A case in point is afforded by a catalogue (No. 73) recently issued by Messrs. Davis and Orioli, of 37 Museum Street, London, W.C.1. In this list, there is offered for sale a book that the vendors claim to be the hitherto undescribed first printed text of Petrus Peregrinus's treatise "De Magnete". The book in question, a small quarto of six leaves, is entitled "De Virtute Magnetis", and its title page bears the name of Raymundus Lullus as author; but no date or place of printing is indicated. The text is almost identical with that of the edition of Peregrinus's treatise published at Augsburg in 1558, hitherto regarded by bibliographers as the first printed edition. The original "Epistola De Magnete" was written in the thirteenth century, probably in 1269, and several early MSS. copies exist. In a long and interesting note, Messrs. Davis and Orioli give reasons for believing the book they describe to have been printed at Rome by E. M. Silber, not later than the year 1520. They state that, in the past, Peregrinus's treatise has been ascribed both to Raymond Lull and to Roger Bacon, and it is suggested that these authors' names may have been used in a general way during the Renaissance as possible authors of any scientific works. While the 1558 edition is a book of extreme rarity, Messrs. Davis and Orioli have so far only been able to trace one other copy of "De Virtute Magnetis", that in the Bibliothèque Nationale, Paris.

South African Marine Fishes

IN a recent descriptive account of "The South African Marine Fishes of Commercial and Angling Importance" by J. M. Marchand (Dept. of Commerce and Industries: Fishery Bulletin No. 2), an attempt is made to provide a handbook for the convenience and use of persons interested in South African sea fishes from the commercial point of view, for sportsmen, and for teachers of biology in South African schools. It is pointed out in the introduction to this work that it is "not intended for the pure scientist, and will be of small if any value to such individuals, due to the limited number of species dealt with, the total lack of classification keys and the brevity of the descriptions". Owing to the brevity of the descriptions, much reliance will have to be placed on the photographic illustrations in making identifications of fishes not already known. This is most unfortunate, for the great majority are so lacking in detail as to be almost useless for this or any other purpose. Some of them, for example, the photograph of *Raia clavata* on p. 52 and of *Arnoglossus pectoralis* on p. 67, are little more than dark blotches on the paper. When, for any reason, detailed drawings cannot be used, simple but accurate outline sketches are infinitely preferable to poorly reproduced photographs for the illustration of a handbook of this kind.

Indian Industrial Publications

THE Indian Industrial Research Bureau has issued a bibliography of industrial publications published in India since 1921 (Bulletins of Indian Industrial Research. No. 1: Bibliography of Industrial Publications published in India from 1921. Pp. iii+257. Delhi: Manager of Publications, 1936. 4.6 rupees; 7*s.* 3*d.*). The first part consists of a list of papers arranged chronologically according to publications, which enables readers readily to ascertain the papers published by each local government, government department, society, etc. Publications available in the Library of the Industrial Research Bureau are indicated. The second part is a classified subject bibliography arranged according to the Universal Decimal Classification. The third section of the bibliography comprises a combined alphabetical author and subject index.

Natural History Magazine

THE October number of this British Museum publication contains an interesting account of the remounting and preservation of the famous Cranbourne meteorite, the conclusion of a long description of the Museum's East African Expedition, and a paper on vermin, based upon Steele Elliot's Bedfordshire records. We record with regret the concluding paragraph of the number: "The Trustees of the British Museum have decided to cease the publication of the *Natural History Magazine* after the issue of the present number, which completes the fifth volume". The experiment has not been long-lived, and as members of the reading public we should attribute its failure to the price charged for what is essentially Museum advertisement and propaganda, and to the tendency of contributors to forget that lightness of hand as well as solid fact is a necessary ingredient in attractive writing.

Index to the *Geographical Review*

THE *Geographical Review* (the quarterly journal of the American Geographical Society) for the ten-year period from 1926 to 1935 contains 7,000 pages of articles, record items, and book reviews, including more than fifty articles on the geographical results of important expeditions, most of them written by the expedition leaders themselves. To make this great mass of geographical material available in organized form, the Society has now prepared an analytical index of 373 pages covering this ten-year period. The price of the index is: unbound, 4.50 dollars; bound, 5.25 dollars. The index to vols. 1–15, 1916–25, of which there are still a limited number of copies available, is offered along with the index to vols. 16–25, at a special price of 8.00 dollars unbound, or 9.50 dollars bound, for the two indexes. These may be obtained from the American Geographical Society, Broadway at 156th Street, New York, N.Y.

Medical Peace Association

A MEETING of medical practitioners and other scientific workers to consider the subject of aerial warfare and means of defence against it will be held in the Hastings Hall, British Medical House, on Wednesday, November 25, at 8.30 p.m. The chair will be taken by Dr. E. P. Poulton, and speakers will include Dr. Stella Churchill, Dr. Robert Edbrooke, Mr. R. Makinnon Wood and Dr. L. A. Rawlings. It is hoped that there will be a full discussion of the whole subject, and particularly of the attitude which the medical profession might reasonably adopt towards it. Information about the Medical Peace Association may be obtained from the Hon. Secretary, Dr. Cecile Booysen, 12 Kent Terrace, N.W.1.

Nutrition in the Colonial Empire

THE Prime Minister has appointed a Committee of the Economic Advisory Council with the following terms of reference: "(1) To survey the present state of knowledge in regard to nutrition in the Colonial Empire in the light of the replies received to the circular dispatch addressed by the Secretary of State for the Colonies on April 18, 1936, to the Officers Administering the Governments of Colonial Dependencies. (2) To advise from time to time as to the measures calculated to promote the discovery and application of knowledge in this field." The Committee is constituted as follows: Earl De La Warr (chairman), Prof. E. P. Cathcart, Mr. G. L. M. Clauson, Dr. Philippa C. Esdaile, Prof. Noel Hall, Dr. J. M. Hamill, Mr. Francis Hemming, Mr. E. M. H. Lloyd, Prof. Edward Mellanby, Sir John Orr, Dr. Audrey Richards, Mr. H. S. Scott, Sir Thomas Stanton, Mr. F. A. Stockdale, Mr. Hans Vischer. The secretaries to the Committee are Mr. D. H. F. Rickett (Economic Advisory Council) and Mr. C. G. Eastwood (Colonial Office).

Announcements

MME. JOLIOT-CURIE has resigned her appointment of Under-Secretary for Scientific Investigation in the French Cabinet to occupy a chair in the Faculty of Natural Science at the Sorbonne, and has been succeeded by Prof. M. Jean Perrin, For.Mem.R.S., known for his work on atomic chemistry, and Nobel prizeman for physics in 1926.

DR. WOLFGANG HEUBNER, professor of pharmacology at the University of Berlin, has been elected an honorary member of the Biological Society of Vienna and of the Imperial Leopold Caroline German Academy of Natural Philosophers at Halle.

PROF. FERDINAND HUEPPE, of Dresden, emeritus professor of hygiene in the German University at Prague, has been awarded the Goethe Medal for Science and Art by the Chancellor of the Reich in recognition of his services in connexion with physical training.

AT the thirty-ninth Congress of the International Law Association for the Protection of the Civilian Population against Modern Warfare, recently held in the Cour de Cassation of the Paris Palais de Justice, a committee was formed to consider the question of the protection of the civilian population against the new engines of warfare, and especially aerial bombardment. The work of the Committee will be carried on in close association with the International Committee of the Red Cross and the International Association for the Protection of Humanity recently founded at Monaco.

ADVISORY LEAFLET No. 272 of the Ministry of Agriculture directs attention to the disease fowl paralysis, which is unfortunately becoming more common. The cause is not known, and no treatment of proved value is available, but the disease can be minimized by removing weak birds, and by not breeding from infected stocks.

CULTIVATION and distillation of peppermint form the subject of Advisory Leaflet No. 98 of the Ministry of Agriculture. Two varieties of this fragrant herb are recognized, namely, black mint, *Mentha piperata* var. *officinalis*, and white mint, *M. piperata* var. *vulgaris*. Harvesting and distilling are described in detail, and the effects of the fungus disease, *Puccinia menthæ*, are considered. Peppermint might be grown with advantage on a larger scale in Great Britain.

THE resumption of work in the technical schools and colleges gives special value to the issue of Foyle's Technical Catalogue (London: W. and G. Foyle, Ltd.) which contains particulars of new and second-hand books on more than 450 subjects coming within the range of applied science.

THE latest catalogue of old scientific books issued by E. P. Goldschmidt and Co., Ltd., of Bond Street, W.1 (No. 40. Old Science and Medicine) includes 216 items, many of great interest, on a variety of subjects, and contains a number of facsimile and other illustrations. Among the books offered for sale are copies of the first edition of Gilbert's "De Magnete", and of an edition of this work printed at Stettin in 1633.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Assistants, Grade II and III (engineering) in the Admiralty Technical Pool—The Secretary of the Admiralty (C.E. Branch), Whitehall, London, S.W.1 (November 2).

A heating and ventilating engineer in the Directorate of Works and Buildings of the Air Ministry—The Secretary (W.B. 9), Air Ministry, Adastral House, Kingsway, W.C.2 (November 14).

A research assistant in the Department of Oil Engineering and Refining, University of Birmingham—The Secretary (November 18).

A junior lecturer in civil engineering in the University of the Witwatersrand—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (December 2).

Structural engineering assistants in the Designs Branch of the Directorate of Fortifications and Works at the War Office—The Under-Secretary of State (C.5), The War Office, London, S.W.1 (Quote Appts./2).

An acting editor to the Royal Scottish Geographical Society—The Secretary, Synod Hall, Edinburgh.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 804.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Vitamin Nature of Flavones

IN a previous note[1] we reported on the favourable effect of flavones upon the resistance and permeability of the capillary wall in certain pathological conditions.

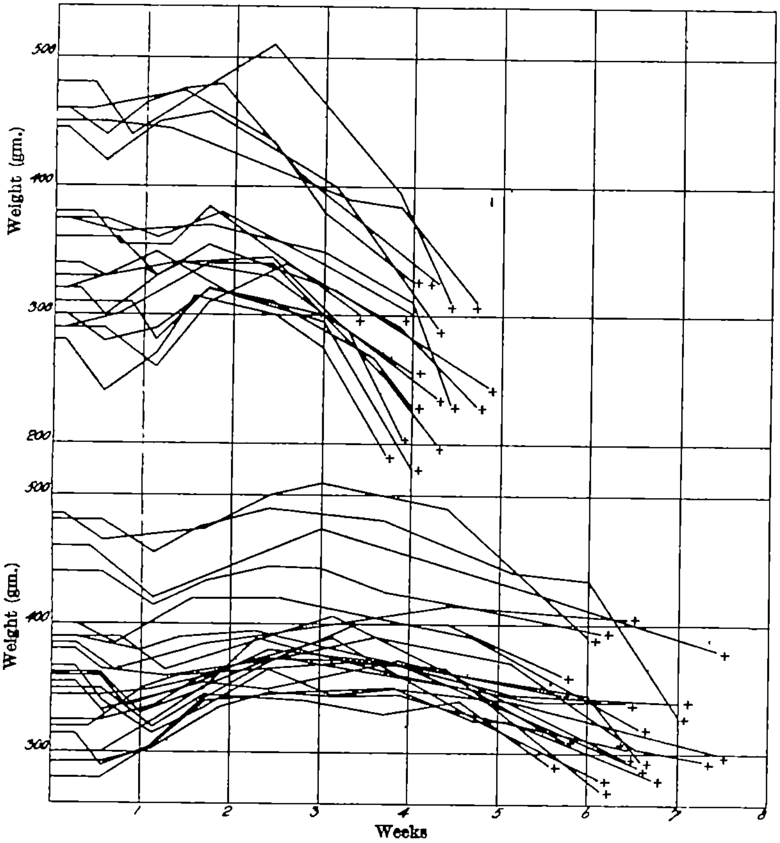

FIG. 1. Weight curves of guinea pigs receiving a scurvy diet without (above) and with (below) the addition of 'Citrin'.

The substances responsible for this activity were tentatively termed 'vitamin P'. The acceptance, however, of the vitamin nature of these dyes depended on the experimental demonstration of the symptoms of deficiency.

Thirty-eight guinea pigs, weighing 280–485 gm., were placed on the Sherman - La Mer - Campbel scurvy diet. The components of the food were autoclaved for one hour and a half at 120° C., ammonia being added to the water of the autoclave. Twenty-one of the animals received 1 mgm. 'Citrin'[2] daily, this substance being the crystalline flavone fraction of lemon juice. A smaller additional group of animals received mixed food.

The weight curves of the animals (17), receiving the scurvy diet only, are represented in the upper part of Fig. 1. The curves of the animals end with death. They show the usual rapid fall after the second week of the experiment, death occurring on average at 28·5 days. The weight declines on the average from 359 gm. to 242 gm.

The data of the second group, receiving 'Citrin', are represented in the lower part of Fig. 1. The administration of flavone was discontinued at the end of the sixth week. Compared with the first group, these animals live distinctly longer, on the average 44 days. At 34-38 days no animal from this group had died, while all animals in the first group were dead. There is also a marked difference in the weight curves, which fail to show the pre-mortal rapid decline, the average weight of 365 gm. falling to 342 gm. only.

Since the food contained no ascorbic acid, the animals could not be expected to live indefinitely. All the animals of both groups showed the typical clinical symptoms of scurvy. On autopsy all the animals showed the typical fragility of bones, looseness of teeth and swelling of joints. There was, however, a very marked difference in the intensity of hæmorrhages in both groups. In our protocols the hæmorrhages were noted, according to their extent, by one, two or three crosses. The relation of the number of crosses given per 100 animals in the first and second group was 212 to 68 for hæmorrhages of the costal joints, 77 to 14 for intestinal hæmorrhages, 224 to 71 for different articular hæmorrhages, and 178 to 33 for hæmorrhages in the muscles. The vitamin P seems thus to have a marked and somewhat specific influence on the capillary system. This agrees with our clinical observations.

A third and smaller group of animals, receiving mixed food, showed normal growth. A preliminary experiment with half the number of animals gave identical results.

These results suggest that experimental scurvy, as commonly known, is a deficiency disease caused by the combined lack of vitamin C and P.

This research was sponsored by the Josiah Macy, Jr., Foundation, New York.

occurs; they are as pronounced with pepsin, which does not dissociate, as with hæmoglobin which does. The specificity of amides for both effects and the repeated occurrence of the amide bond in proteins suggest that the two phenomena may nevertheless have related causes. They do not appear to be related to changes in dielectric constant. Urea and formamide solutions have dielectric constants greater, and acetamide solutions much smaller, than that of water. Glycine solutions, with dielectric constants still higher than those in urea, are without effect on dissociation, and have relatively small influences on solubility.

These measurements were made possible by the facilities provided by Prof. The Svedberg at Uppsala, and by Sir Joseph Barcroft at Cambridge. They owe much to the advice and assistance rendered by Dr. K. O. Pedersen at Uppsala, and by Dr. G. A. Millikan and Prof. D. Keilin at Cambridge. Full details will be published elsewhere.

Inhibited Deposition of Stearin from Chilled Olive Oil

WE have observed that the addition of very small amounts of air-blown cacao-butter (Iodine No. = 20) to olive oil permits such oil to remain liquid and free from stearin deposit on storage at temperatures between 2° C. and 4° C. Untreated olive oil in such storage sets solid within 12 hours, whereas we have found the inhibition effect to persist after even four years storage at 2° C. (Fig. 1).

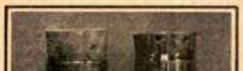

FIG. 1.

The amount of blown cacao-butter required varies from 0·1 to 0·5 per cent, depending on the technique of its oxidation, and the length of time the olive oil is to be stored cool. The inhibition effect is highly specific in that: (*a*) no other blown oil or fat serves so well, and (*b*) protection is not afforded to other oils such as arachis, or cotton-seed.

This inhibition phenomenon has been found to furnish a quantitative guide to the very remarkable property of blown cacao-butter to prevent fat-bloom in stored chocolate, in which respect it is greatly superior to lecithin or other anti-bloom agents.

Our investigations will be fully reported elsewhere.

Increase of Diamagnetic Susceptibility on the Death of Living Cells

ACCORDING to E. Bauer's theory, the lack of equilibrium in living systems is due to an excited state of the protein molecules of the protoplasm. The maintenance of this state is operated through the process of metabolism, collisions of the second kind between the molecules of the protoplasm and those of the food substance leading to an activation of the latter, and their chemical energy, set free in the reaction, being used to maintain the active, excited state of the molecules of the living substance[1].

If now this active state of the molecules of the living substance consists in an electronic excitation or—what seems more probable—in the existence of free valencies, which on death are saturated within the protein molecule, then the living and dead substance must differ with respect to its magnetic susceptibility, since, owing to the falling out of the paramagnetic component, the resulting diamagnetic susceptibility must increase on death.

Measurements to check this point were carried out by us with the assistance of the magnetic laboratory of the Ural Physico-Technical Institute (formerly at Leningrad, now at Sverdlovsk). They gave a positive result. In the case of yeast and suspensions of bacteria (*B. coli*, *B. proteus*) we found an increase of diamagnetic susceptibility on death amounting to 4 per cent, the maximum possible error not exceeding 0·7 per cent. This result was independent of the way the cells were killed: beating or cooling down with liquid air produced the same effect as spontaneous death. It is important to note that denaturation of native protein did not affect the magnetic susceptibility.

[1] A detailed presentation of the theory has been given in E. Bauer's "Theoretical Biology" (Russian), 1935. A brief sketch and a few applications in *Biodynamica*, No. 14, 15 (1936).

Nitrogen Losses in Green Plants

A FEATURE of the nitrogen metabolism of plants which has received little attention is the possibility of considerable losses of nitrogen during the process of nitrate reduction. It is generally agreed that this process leads first to the production of nitrites, and the presence of nitrites in plants actively engaged in nitrate reduction has been shown by Eggleton[1]. As plant tissues are normally acid, nitrous acid should be present, and this should combine with mono-amino nitrogen to give elementary nitrogen. It is well known that this reaction is rapid *in vitro*[2]. It has been shown by Irving and Hankinson[3] that *Elodea* produces elementary nitrogen when immersed in solutions containing nitrates and asparagine as a source of amino-nitrogen.

Two examples in which such losses of nitrogen occur have recently been observed by us and studied in some detail. In one of these, pure cultures of *Chlorella vulgaris* growing (in the dark) in a nutrient medium (*p*H 5·8) containing glucose (10 gm. per litre) and sodium nitrate (0·26 gm. per litre), retained in the cells 3·4 mgm. of nitrogen out of 13 mgm.

in each culture flask. The external medium at this time contained only 1·1 mgm. of nitrogen (Kjeldahl-Gunning) of which 0·6 mgm. was nitrate nitrogen. Thus 8·5 mgm. of nitrogen were lost, presumably in elementary form.

Similar losses of nitrogen have been observed when daffodil leaves were floated aseptically on glucose media (3 per cent, buffered by phosphate mixtures to *p*H 5·4) containing an inorganic source of nitrogen such as ammonium or potassium nitrate. Of the nitrogen absorbed from the medium, about half is normally lost, the remainder being retained in the leaves. In contrast, if organic sources of nitrogen (such as asparagine, alanine or urea) are used, the whole of the nitrogen absorbed can be recovered in the leaves. It may be noted that considerable losses of nitrogen are always associated with low amino-nitrogen content of the leaf tissues.

Route of Migrating Parasites in Ruminants

MR. W. M. WEBSTER, veterinarian of this College, has shown me an adult specimen of the lungworm *Dictyocaulus filaria* that he found in an undamaged condition in the small intestine of a hogget.

This observation, it appears to me, reveals something of the movements of parasites that undergo the lung journey in ruminants.

In the first place, the specimen must have been coughed from the lungs and then swallowed. It does not seem possible that it could have been involved in the process of rumination for, on account of its relatively large size, it would have been crushed The conclusion therefore follows that the worm during its journey to the small intestine could not have spent a period in the rumen.

Perhaps the eggs or larvæ of the various lungworms and other worms, in their passage from the lungs, behave in a similar manner, and proceed directly from the gullet to the reticulum.

Resonance Structures of Carbon Dioxide, Carbonyl Sulphide and Carbon Disulphide

BY comparing experimental heats of formation with bond energies derived from compounds without alternative Lewis structures, Pauling and Sherman[1] deduce resonant structures for carbon dioxide, carbonyl sulphide, and carbon disulphide, of the type :

$$\overset{+}{:}O:::C:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{O}}:\rightleftharpoons:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{O}}:C:::O:^{+}$$

but the impossibility of obtaining a valuation of the bond energies of partially ionic bonds from thermal data does not permit of a more penetrating analysis of the resonance of these compounds along these lines.

Gray and Cruickshank[2] have demonstrated the presence of resonance in certain compounds by considering diamagnetic susceptibilities. As partially ionic bonds can be evaluated magnetically, a greatly increased number of theoretically possible structures can be considered.

The diamagnetic susceptibilities of the above compounds are :

$$CO_2\ -20{\cdot}80^3\ ;\ COS\ -32{\cdot}36\ ;\ CS_2\ -42{\cdot}29,$$

and these experimental susceptibilities can be compared with the theoretically possible states of the molecules and with Pauling's resonance energies.

	E	Reson. *E*	Susceptibility of		Expt. suscept.
			$X{=}C{=}X$	$:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{X}}:C:::X\overset{+}{:}$	
CO_2	16·79	1·37 ve.	−2·73	−20·80	−20·80
COS	14·55	0·84 „	−12·31	−38·00 −42·79 } *	−32·36
CS_2	12·46	0·46 „	−22·54	−59·84	−42·29

* The two states $:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{O}}:C:::S\overset{+}{:}$ and $:O\overset{+}{:}::C:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{S}}:$ do not have identical susceptibilities. All susceptibilities are × 10^{+6}.

Neither of the calculated values for the structures O=C=O, O=C=S, S=C=S, agrees with the experimental value, this being what one would expect from the suggestions of Pauling and Sherman, but in the case of carbon dioxide a resonance

$$\overset{+}{:}O:::C:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{O}}:\rightleftharpoons:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{O}}:C:::O:^{+}$$

would give for the susceptibility −20·80, which is exactly what is found experimentally (−20·80), a convincing demonstration of resonance in the carbon dioxide molecule.

The introduction of one sulphur atom is accompanied by a fall in resonance energy. In carbonyl sulphide two ionic states are possible. Direct resonance between these states gives too high a calculated susceptibility, but the existence of an intermediate state O=C=S enables the experimental value to be accounted for.

$$:S\overset{+}{:}::C:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{O}}:\rightleftharpoons S{=}C{=}O\rightleftharpoons:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{S}}:C:::O:^{+}$$

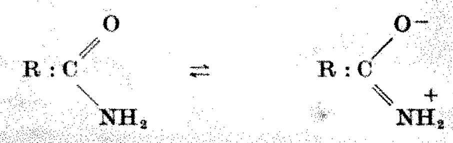
If equal times were spent in these three states, the calculated susceptibility would be −31·02, compared with the experimental value −32·36.

A further fall in resonance energy takes place on passing to carbon disulphide, and in agreement with this, resonance between

$$:\underset{\cdot\cdot}{\overset{\cdot\cdot\,-}{S}}:C:::S\overset{+}{:}\rightleftharpoons S{=}C{=}S$$

is suggested by the diamagnetic susceptibility of carbon disulphide (calculated −41·19 ; experimental −42·29).

The resonance in amides suggested by Pauling is also confirmed magnetically :



If equal times were spent in each state the calculated susceptibility would agree closely with the experimental.

	Calculated	Experimental
Formamide	$-22\cdot39$	$-21\cdot87$
Acetamide	$-34\cdot29$	$-33\cdot75$

In thioacetamide, however, there is not the same resonance, as the experimental susceptibility indicated a stable doubly bound structure.

These results show that the study of diamagnetic susceptibilities can be applied to problems involving quantum mechanical resonance, and allowing for relatively small experimental errors, seem to indicate a distinct tendency for molecules to spend nonfractional times in the possible states.

The deduction of the theoretical values for sulphur bonds which were not given by Gray and Cruickshank will be published elsewhere.

Constitution of Phosphorous Acid and the Phosphites

MENZIES[1] and Bär[2] showed that it is possible to obtain Raman spectra with crystal powders in which at least some of the stronger lines of the substances are recorded. I have shown[3] that the technique of obtaining the spectra with powders is vastly improved if a pair of complementary filters is used, one having a sharp cut-off on the longer wave-length side between the source and the scattering substance to isolate a definite exciting line from the exciting source of light, and the other having a sharp cut-off to the shorter wave-length side in the path of the scattered light in order selectively to weaken or absorb the exciting wave-length. Using this device, it is now possible to record the faintest lines and bands in the spectra of crystal powders and even of amorphous solids by giving suitably long exposures.

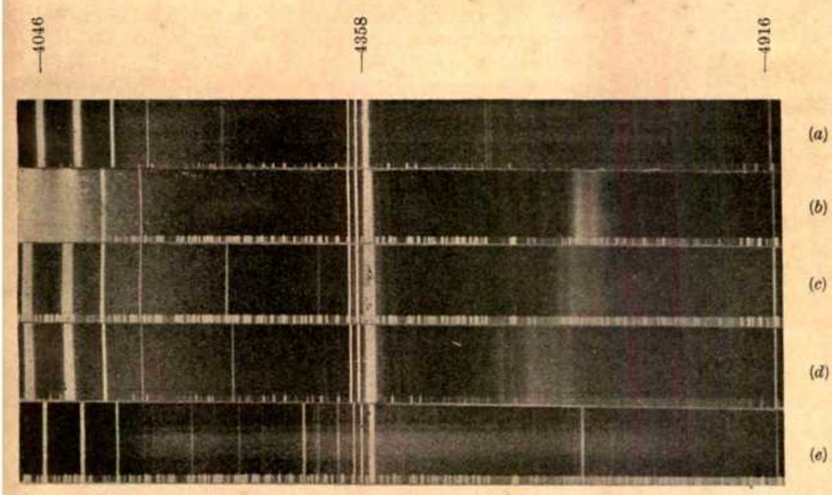

FIG. 1. Raman spectra of (*a*) crystalline phosphorous acid, (*b*) ammonium chloride, (*c*) hydroxylamine hydrochloride, (*d*) hydrazine hydrochloride, and (*e*) naphthalene.

Illustrations of the power of the new technique are furnished by Fig. 1 in which are reproduced the Raman spectra of crystalline phosphorous acid, ammonium chloride, hydroxylamine hydrochloride, hydrazine hydrochloride, and naphthalene, λ 4046 being the exciting wave-length in all cases. While Bär was able to record only five Raman frequencies in the spectrum of naphthalene crystals, not less than twelve frequencies can be identified in the above photograph. The N—H bands in the solids of the ammonium group have been recorded clearly and distinctly for the first time.

One of the interesting results furnished by the new technique relates to the constitution of phosphorous acid. The Raman spectrum of this acid shows a pair of sharp and intense lines with the frequency shifts 2,486 and 2,509 cm.$^{-1}$. These frequencies presumably arise from a P—H vibration, and show that the constitution of the acid is  $O = P\begin{cases} H \\ OH \\ OH \end{cases}$ This conclusion is supported by the Raman spectrum of sodium phosphite, Na_2HPO_3, which shows a strong Raman frequency at 2,335 cm.$^{-1}$.

Water under the Western Ice Cap in North-East Land

AT the station maintained from September 1935 to June 1936 near the centre of the Western Ice Cap in North-East Land (80° N., 20° 30′ E., approximately) by the Oxford University Arctic Expedition 1935–36, it has been found that, contrary to expectation[1], the ice-cap is not frozen to any great depth. While a shaft was being excavated in the *firn* beneath the station, a *concealed* crevasse was discovered—there was absolutely no trace of it at the surface, even during the period of summer thaw—and investigated to a distance of some hundreds of feet in the horizontal direction. At a depth of some 70 ft. below the surface was a lake of *water* varying in depth from 3 ft. to 6 ft. The bed of the lake was of ice.

There is reason to believe that this water remains in the liquid state throughout the year, and preliminary calculations give an estimate of the order of fifty years for the age of the crevasse at water-level.

It is hoped to publish fuller results, with detailed figures, later.

Transition Curve for the Destruction of Supraconductivity by an Electric Current

In former experiments with a tin ring[1] we found that, when supraconductivity is destroyed by an electric current, the field-strength H_{kj} corresponding to the critical current is equal to the critical magnetic field-strength H_k. In order to measure H_{kj} we have now employed the exceedingly high thermal conductivity of He II. Through a tin wire of radius 0·0056 cm. immersed in He II, we were able to send an enormous current ($1 \cdot 5 \times 10^5$ amp./sq. cm.) without noticeably heating the wire or the helium, which enabled us to determine the entire transition curve.

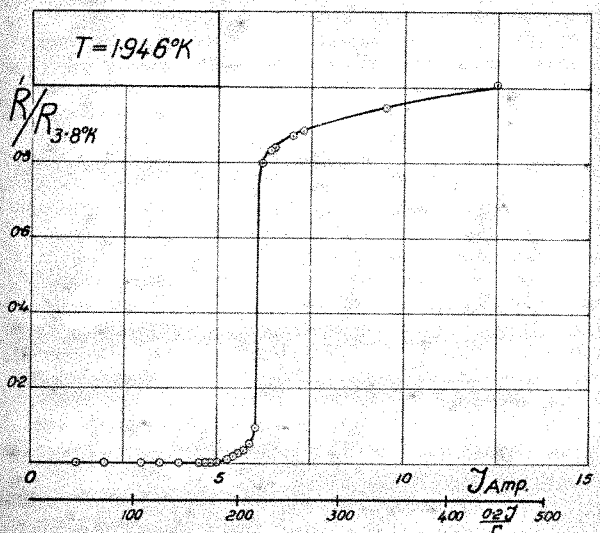

Fig. 1.

The relation between R and I—the second scale is for $H_{kj} = 0 \cdot 2\ I/r$—is depicted in Fig. 1. The resistance unit is taken as $R_{3\cdot 8°\text{ K}}$, that is, the resistance at 3·8° K.

Results : (1) We found that the sharp jump in the resistance corresponds to $H_{kj} = 219$ gauss, which within the limits of experimental error—a few per cent—coincides with the field-strength formerly observed[2], which was 218 gauss.

(2) The resistance rises steeply only up to $0 \cdot 8\ R_{3\cdot 8°\text{ K}}$. Afterwards it rises gradually to the normal value for the non-supraconducting metal.

Points from Foregoing Letters

Curves showing the effect of 'Citrin'—the crystalline flavone fraction of lemon juice—in prolonging the life of guinea pigs fed on a scurvy diet are submitted by A. Bentsáth, St. Rusznyák and Prof. A. Szent-Györgyi. The active principle (vitamin 'P') appears to have a marked influence upon the capillary system.

A method of estimating ascorbic acid (vitamin C), depending upon the addition of excess of methylene blue and titrating the excess with titanium trichloride, is described by Dr. Imre Gál. On the same subject, H. Cheftel and M.-L. Pigeaud state that by cooling the ascorbic acid solution to 0° C. it is possible to slow down its rate of oxidation and to obtain more consistent results by the method of Harris and Ray (titration with 2 : 6 dichlorphenol indophenol in acid solution).

By means of diet experiments on mice, Drs. A. and M. Lasnitzki have investigated the question whether 'mineral' and 'biological' potassium are equivalent, in view of the possibility that the isotopic constitution may be different. Body-weight and duration of life are affected, but the results are complex.

From the change in the diffusion constant and the rate of sedimentation in the supercentrifuge, it has been deduced that horse hæmoglobin in concentrated solutions of urea, acetamide and formamide, is partly dissociated into particles of half the original weight. Dr. J. Steinhardt puts forward further support for this view and finds that there is no denaturation in the process. He has investigated the properties of methæmoglobin and hæmochromogen prepared from the dissociated hæmoglobin, and he discusses their bearing on current theories of the equilibrium between hæmoglobin and oxygen.

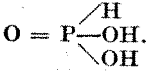
Small quantities of air-blown cacao-butter added to olive oil have the specific property of preventing cloudiness and deposition of stearin on storage at 2° C., according to Dr. W. Clayton, S. Back, R. I. Johnson and J. F. Morse.

A difference in the diamagnetic susceptibility of living and dead bacteria is reported by Prof. E. Bauer and A. Raskin. This, they claim, supports Bauer's theory that the lack of equilibrium in living systems is due to an 'excited' state of the protein molecules of the protoplasm.

Two cases of loss of nitrate (due probably to formation of free nitrogen), one in a culture of the unicellular freshwater alga, *Chlorella*, and another in the presence of daffodil leaves, are reported by Dr. W. H. Pearsall and M. C. Billimoria.

Dr. A. Clow and J. M. C. Thompson find that the diamagnetic susceptibility of carbon dioxide agrees with that calculated from the 'resonance' energy according to the formula of Pauling and Sherman. In the case of other compounds, differences occur between the calculated and the experimental values, and the authors suggest certain possible interpretations.

Using an improved device for obtaining Raman spectrograms with crystal powders, R. Ananthakrishnan has obtained evidence indicating that the constitution of phosphorous acid should be represented by



$$O = P\begin{matrix} \diagup H \\ -OH \\ \diagdown OH \end{matrix}.$$

Research Items

Garments from Yunnan

The late Prof. Augustine Henry, well known as an authority on forestry, was stationed in southern Yunnan as an officer of the Chinese Customs in the last decade of last century. He then made a study of the little-known peoples of the country, including the Lolo, more correctly known as the Nosu. A small collection of clothing which he brought back to England, described as 'Lolo', but now shown to be Miao, was presented to the Manchester Museum by Mrs. Henry. It has since been studied and described by the Misses Laura E. Start and Mabel C. Wright (*Notes from the Manchester Museum*, No. 37 : Repr. *Mem. Manchester Lit. and Phil. Soc.*, 80 ; 1935–36). The garments consist of four coats—a short-waisted pullover with long sleeves and the chief embroidery at the waist, two linen coats, sleeveless and short-sleeved, with shoulder and collar decoration, and a Chinese derivative, little worn by Miao women—and lastly a short skirt. All differ in technique and style from Chinese work. The description 'Lolo' is shown to be incorrect, as Lolo women wear jackets and long petticoats (which are rarely heavily embroidered) silver ornaments and a long felt cloak. This last is a prominent feature in the clothing of both sexes. The Miaos, who are tenants or serfs of the Lolo, call themselves *mp'eo*, a sound which means "embroidery". The amount of embroidery on the clothing of a Heh Miao young woman is astonishing ; and it takes them years to embroider the jackets or skirts, in which they hope to be married. The embroidery on the garments now in the Manchester Museum, the only ones of their kind in an English museum, clearly indicates their origin. They belonged either to the concubine of a Nosu chief or to serfs on a Nosu estate. The materials used are local cloths made from flax or wool, with trimmings of silk, cotton and wool. Cotton cloth is obtained from the Shan, the only people of the region who now weave cotton. The ornament, hand sewn, is mainly geometric, and well placed. Possibly Chinese influence can be traced ; but Shan influence is more marked, for example, in the use of coloured cloths applied in strips and small pieces, in borders, and joined in large pieces to give variety of colour. Two unusual methods employed in making patterns are folding to produce a strip effect, and a stitching giving a brocade texture.

Mound Builders in Louisiana, U.S.A.

An examination by Mr. Winslow M. Walker in 1931–32 of the remains of a group of mounds in Louisiana has preserved evidence relating to early indigenous culture, which was in danger of being lost entirely. The mounds, upon which now stands the township of Jonesville (formerly Troyville) in Catahoula Parish, near the junction of the Tensas, Black, or Ouachita, and Little Rivers, eighteen miles west of the Mississippi, are thought to be identical with the capital city of the Province of Anilco visited by de Soto in 1542. They were seen by Duncan and Hunter in 1804. The remarkable feature of the group was then a conical mound raised on a pyramidal platform with two terraces, and there is evidence to show that it had a total height of eighty feet. This would make it second in height only to the Cahokia mound in Illinois. It was partially destroyed in the American Civil War, and finally levelled in 1931, when great sheets of cane, pottery, bones and variously coloured clays were brought to light. The neighbouring mounds have been used for house sites, but enough remained of the great mound beneath the levelled surface to yield to Mr. Walker's excavation something of the cultural history and evidence of the method of construction (*Bull.* 113, *Bureau of American Ethnology*). Excavation of part of a burial ground near the river brought to light a number of burials ; but there was no certain indication of a connexion between the human remains and the former inhabitants of the mounds. The artefacts found in the remains of the mound were not numerous, the most important being the pottery, which though extremely fragmentary, afforded material for a classification into a number of types. The most remarkable feature was the constructional use of cane in layers of some thickness. There is evidence of at least two periods of occupation or construction, of which the earlier resembles that of the Hopewell Mound builders of Ohio, and the second inaugurated important structural changes. The last inhabitants of the site may have been the Taensa or the Avoyel, both related to the Natchez, who were broken up by the French in the eighteenth century.

Inheritance of *l*-Xyloketosuria

There are known to be at least two types of the rare chronic pentosuria, differing in the nature of the pentose sugar found, one being optically inactive *dl*-arabinose and the other *l*-xyloketose. The latter—a quite abnormal sugar—is now well authenticated, and a simple new test devised by Lasker and Enklewitz facilitates its identification. The same authors have adduced evidence that *d*-glucuronic acid is the precursor of the pentose, though on theoretical grounds the conversion is difficult to follow from the formulæ of the two substances. At any rate the administration of glucuronic acid causes a greatly increased elimination of this pentose in the urine. What is more interesting is the observation (*Human Biology*, 8, No. 2 ; 1936), based on the study of twenty pentosuric families, as to the inheritance of *l*-xyloketosuria. The urine pentose of thirty-seven individual members has been identified as this sugar. The disease is very rare in the general population, but is frequently found in the families of known cases. Most cases are among Jews. The disease was present in children of ten families in which neither parent shows evidence of it. One case was a child of first cousins. These facts are regarded as indicating strongly that *l*-xyloketosuria is inherited as a recessive character and controlled by a single recessive gene.

Shore Fauna of the Arctic

THE East Greenland Polar Current bathes the shores of east Greenland in low-temperature water and gives rise to much more severe conditions there than obtain on the west coast. Holger Madsen has surveyed the area 70° 29′ N. to 74° 05′ N., and finds that life in the littoral and supralittoral zones is limited to comparatively few species ("Investigations on the Shore Fauna of East Greenland with a Survey of the Shores of other Arctic Regions". *Medd. Grønland*, 100, No. 8; 1936). *Fucus vesiculosus*, *Balanus balanoides*, and *Littorina saxatilis* var. *grœnlandica*, all of which occur in the same longitude on the west coast, are absent here, and the common forms are oligochætes, dipteran larvæ, and certain mites and nematodes. The first two may be present in numbers as great as 18,000 and 27,000 per square metre respectively. In the first part of this paper, a detailed account is given of the faunas of the different types of facies—rocky, gravel, clay, etc., and in the second part the area is compared with the west coast of Greenland and with the other known arctic and subarctic shores. The survey of the scattered literature on this subject is of particular value.

Fishes from West Borneo

Treubia (Deel 15, Aflevering 3 ; 1936) contains a paper by Dr. J. D. F. Hardenberg (Laboratorium voor het Onderzoek der Zee, Batavia) "On a Collection of Fishes from the Estuary and Lower and Middle Course of the River Kapuas", in which he describes a large number of interesting species, adding many records to the fauna of Borneo. These were to a large extent collected from the fish-market at Pontianak, caught in an affluent of the River Kapuas and on the adjoining coast. Others came from streams connected by numerous water courses with the Kapuas, and from the Peniti River, the last coming from farther up the river and from some of the great lakes near. The author gives notes wherever possible on the various species used as food, their local names and feeding habits besides the morphological descriptions.

Anatomy of a Nyphomyiid Fly

IN 1932, Mr. M. Tokunaga announced the discovery of a new dipterous insect in Japan, which he described as *Nymphomyia alba* gen. et sp. nov. It exhibited a combination of peculiar features which led him to establish the family Nymphomyiidæ for its inclusion. He now discusses the nervous, tracheal and digestive systems of this insect (*Philippine J. Sci.*, 59, No. 2, 189 ; 1936). As regards the nervous system, he describes the ventral nerve cord as consisting of three thoracic and eight abdominal ganglia. The presence of eight separate ganglia in the abdomen is frequent among dipterous larvæ but very rare in the adults of the higher Pterygota. In the tracheal system there are only two pairs of functional spiracles, namely, meso- and metathoracic, while vestigial closed spiracles are present in the abdomen. The tracheal system itself is very simple, consisting of two main longitudinal trunks with very few transverse anastomoses. The alimentary canal is of relatively simple structure : there is no trace of crop or sucking stomach, and histologically the gut shows no evidence of serving a digestive function. The Malpighian tubes are only two in number and open into a common ventral excretory chamber. The structure of the cells of the tubes are peculiar in that small intracellular tubuli open into a common central canal.

Studies of Frost Hardening

IN a very suggestive investigation upon this subj (*Canadian J. Res.*, 14, Sec. C, Aug. 1936) by Levitt and G. W. Scarth, comparisons were made the plasmolytic method of the permeability of cells of corresponding tissues of various herbace and woody plants in the unhardened and harde state. Frost hardening of herbaceous seedlings carried out by keeping them for some days in a c chamber, in the case of the woody plants ; in addit to twigs thus artificially hardened, comparis were made with tissues brought in from the o country where they were undergoing the nor seasonal hardening during winter. The result been to show an unexpectedly definite effect, a mar increase in permeability with hardening. It is c cluded that cell permeability in the hardened st shows a better correlation with ability to resist fr than any other character so far examined. permeability change is most marked towards a like potassium nitrate ; the change is less mar towards polar non-electrolytes with small molec such as urea ; there is no change towards an apo substance such as urethane. The authors sugg that these phenomena point to an increase in of the aqueous pore surface in the plasma membr as a result of the exposure of the living tissues to c

Hudson Strait Survey

THE sixty-ninth annual report of the Canad Department of Marine for the fiscal year 1935 (Ottawa : J. O. Patenaude, price 25 cents) conta interesting information respecting the explorat survey work now in hand in connexion with development of navigation in Hudson Bay to from the recently established port of Churchill. principal feature of the season's operations was charting of a deep-water channel inside the Dig Islands and close to the continental coast, and tending for a distance of twenty-two miles fr Wolstenholme to the westernmost islet. It is m than a hundred fathoms in depth and so strai that two courses only are required. The new chan called Digges Island Sound, is reported as being free in the late fall for some ten days after the us ship's route, north of the Digges Island, and shortens considerably the distance from the sea places on the eastern side of Hudson Bay and Moosonee in James Bay. The newly charted chan possesses a bleak grandeur. At the eastern entra of the Sound on the mainland side stands C Wolstenholme, with perpendicular walls rising thousand feet from the water's edge. From t great headland, the Sound is walled for several m by enormous cliffs. Thousands of guillemots murres come yearly to these cliffs to breed and, the summer months, the place is alive with th clamour.

Silting of Reservoirs

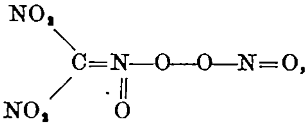
THE problem of the silting of reservoirs by stre carried material and the means of reducing the pro are being widely studied in the United States by Soil Conservation Service of the Department Agriculture. The first report dealing with re sentative reservoirs in the southern areas has b published (Silting of Reservoirs. By H. M. Eal Washington, D.C.). The rapid silting would app to be due to the broad prevalence of soil eros induced by human occupation. The highest r go with agriculture: the lowest with forest cover. In other parts, particularly dry areas, silting is accelerated by over-grazing and the consequent reduction of the plant cover. The prevention therefore of this growing menace seems to lie in the control of soil erosion by improved methods of agriculture, reclamation of steep slopes, extension of forest growth, and restriction of over-grazing. Fire prevention and rapid planting of burnt areas are other ways of reducing silting. The report includes full instruction for reservoir sedimentation surveys.

Scintillations of Zinc Sulphide

THE scintillations produced on a zinc sulphide screen by α-particles have served, as is well known, in counting the number of such particles emitted by a radioactive preparation. Various specimens of zinc sulphide have very different activities in this respect, and the suitability is connected with the size of the crystals, the presence of traces of impurities, etc. In a study of the phenomenon, G. Destriau (*J. de Chimie Phys.*, **33**, 587; 1936) has indicated some further interesting features. The sensitivity of a specimen of zinc sulphide to α-rays is not connected with the phosphorescent properties in relation to light, since a sulphide which is phosphorescent can give no scintillations, and vice versa. The fluorescence under X-rays, on the other hand, is closely related to the brightness of the scintillations. It was possible to produce luminescence in zinc sulphide by the action of an electric field.

Constitution of Tetranitromethane

THE constitution of the compound $C(NO_2)_4$ has recently engaged the attention of the Czechoslovak chemists, Prof. Cyrill Krauz and Dr. J. M. Štěpánek (*Chem. Obzor.*, **11**, 153 and 177; 1936). These authors conclude that none of the structural formulæ previously assigned to tetranitromethane (TNM) fully explains its chemical reactions. Not one, for example, explains its oxidizing properties. The substance can scarcely be regarded as a true tetranitro-compound since one nitro-group is more reactive than the others, and a new structure is suggested, namely:



which accounts for the formation of nitroform as an intermediate and as a decomposition product. Tetranitromethane acts most strongly as an oxidizing agent in alcoholic solution. A peroxide hydrogen atom is given up in the presence of such reducing agents as sulphides, sulphites, arsenites, hydrazine and hydroquinone, with the liberation of nitroform. Iodine is set free from iodides not only in the presence of acids but also in neutral and even weakly alkaline solutions. The above formula also indicates how guanidine, methylamine, ammonia and nitrogen can be derived from tetranitromethane, and its formation by the interaction of silver nitrite and iodonitroform is at once apparent. The compound is not decomposed by anhydrous sulphuric acid or by glacial acetic acid, and the authors obtained no evolution of gas in Lunge's nitrometer on treating tetranitromethane with concentrated sulphuric acid, although with the dilute acid the decomposition became very violent.

Electrical Prospecting and its Uses

IN a paper presented at the Second Congress of the International Commission on Large Dams at Washington on September 10, C. and M. Schlumberger show how to utilize the fact that underground formations differ largely in their electrical resistivity. The electrical current conducted by rocks varies largely with the amount of assimilated water they contain. Rocks like granite, gneiss, marble and all rocks in which the spaces of pores form only a very small fraction of the total volume have a resistivity varying between 200 and 3,000 ohms per cubic metre; for clays, marls, soft limestones, etc., it varies from 10 to 30 ohms. The large differences between the resistivities show that they can be usefully employed to foretell the nature of the foundations on given sites. Since the measurements made are at small depth, the necessary equipment is very light and easily handled. It consists of a potentiometer, a few dry-cell batteries, two reels of cable and copper pegs to make the earth contacts. If it is required to find the exact depth of the bedrock by an electrical sounding, an average of about four measurements per day can be made, but even so the cost is very small when compared to that of mechanical drilling. When a large surface has to be surveyed to determine a suitable site the technique is different, and an efficient operator can make about forty measurements per day, a different method being employed. The results obtained in four practical applications are given: one in France, two in the United States and one in Canada. In predicting the depth of the bedrock in one case, the maximum error made was nine per cent and the average error 6·4 per cent. A translation of the paper, which is in French, is given in *World Power* of September.

Discrete Space-Time

IN the course of five lectures delivered in the McLennan Laboratory of the University of Toronto in January and February 1936, and published in pamphlet form (*University of Toronto Studies, Physics Series*; University of Toronto Press, 1936), Dr. L. Silberstein examined some of the consequences of the hypothesis that both space and time are discrete instead of being continuous. This would imply, for example, that in any finite volume the number of positions that a particle could occupy would be, although very large, not actually infinite, and that in describing its motion all that could be specified would be its position at very short intervals of time, as in a cinematograph film. Such an assumption has much in common with the postulates of quantum theory. Dr. Silberstein shows that discrete space-time is compatible with the restricted relativity theory, at least to a high degree of approximation. But, as no place is left for infinitesimals and hence for covariant tensors, the general or gravitational theory is ruled out. To the ordinary physicist this seems regrettable; but Dr. Silberstein, for reasons not explained, declares that "the generalized relativity theory is far from being firmly established, and its heuristic power, its successful predictions (of which one, that relating to the perihelion motion of Mercury, seems very doubtful) seem to be nearing exhaustion, while certain rigorous conclusions recently drawn from Einstein's general-relativistic theory of gravitation by the writer turn out to disagree with some most fundamental facts of experience".

Methods in Social Anthropology*

IN opening his lecture in memory of Thomas Henry Huxley, Prof. Westermarck said that it was calculated in a peculiar way to call to his mind the first steps he ventured to take in social anthropology nearly fifty years ago, when, being concerned with the origin of marriage, and thinking with other scholars of the time that primitive man lived in a state of promiscuity, he became acquainted with the doctrine of organic evolution and drew the conclusion that the social habits of the anthropoids might throw some light on those of primitive man. It is now to be regarded as amply proved that among many of the apes the social unit is the family, and it may be concluded that the factors which necessitated marital and paternal relations among the apes also presumably operated among our earliest human or half-human ancestors. He went on to point out, however, that apart from its role in the production of instincts, the principle of natural selection does not render us much help in our search for social origins.

In his study of social origins, the sociologist is much better situated than the biologist in his study of organic evolution. Natural selection presupposes organic variation, but scarcely anything is known about the origin of these variations. The causes of social phenomena, on the other hand, are to an almost unlimited degree accessible to the sociologist; and it is his business to find them. The methods of sociology, therefore, are ultimately the methods of finding the causes of social phenomena.

One method of social anthropology is the comparative one. This method starts from the fact that there are great similarities between the products of culture. The task of comparative sociology is not so much to classify these facts as to answer the question why there is this similarity. Tylor, Huxley, Frazer, have all recognized the fact that these similarities may be due to a similarity in the operations of the human mind in like conditions, or they may be due to diffusion or borrowing; and the criticisms of Rivers, Elliot Smith and others to the effect either that the possibility of diffusion is not recognized, or if it is that this involves a contradiction, are not well grounded. It is true that the question whether a certain custom or institution has sprung up independently among the people or tribe practising it, or whether it has been introduced from some other people or tribe, is seldom discussed in comparative treatises. But this by no means implies the assumption of independent origin; on the contrary, when the custom or institution occurs among related or neighbouring peoples, there is, at least in many cases, a tendency almost to take it for granted that it has been derived from a common source. Taking the study of proverbial sayings as an example, peoples have at all times taken adages from each other. But it must always be borne in mind that the resemblance between proverbs may have another cause than diffusion, namely, the people's tendency to express themselves in apophthegmatic sayings, which, owing to their terseness, are apt to become more or less similar in similar situations. The real test of a common origin is, therefore, not the mere similarity of ideas and sentiments revealed in the proverbs, but the similarity of formal expression, with due allowance for modifications that are liable to occur when a saying is adopted from another language and transplanted into a new soil.

Another branch of cultural phenomena in which diffusion has played a prominent part is decorative art. The diffusion may not in every case refer directly to particulars in the design; it may also be an independent effect of the idea underlying it. The patterns used in Morocco were originally to a large extent charms against the evil eye. They are based on two principles, the hand, or its five fingers, and the image of an eye or pair of eyes. Both types of charm are spread all over the Mediterranean, and many of them also farther east, and are proved to have existed since very early times. This does not preclude the possibility of more or less similar representations of protective objects having in certain instances originated independently, which is illustrated by the occurrence of designs or charms on the leather bags of the mountaineers of Morocco in the form of a pair of eyes resembling the capital of an Ionic column. That the capital of an Ionic column may have its origin in a charm against evil protecting the temples of the Greeks would be no wonder; but it is extremely improbable that the Moorish charms have been copied from the Ionic capital. Their resemblance is easily explained by a common belief that the representation of the eyes serves as a protection against the evil eye. Widely distributed, the eye ornament may have a different meaning in different cases, illustrating a weakness in the method of diffusionists, who have a tendency to rely on external resemblances only.

Comparative study further may enable us to discover that certain customs are vestigial forms, so-called survivals—a custom which cannot be explained by present circumstances, but persists in isolation from its original context. In spite of the importance of this principle, there has never been any general theoretical discussion of its proper application, where historical evidence is absent. Two definite rules may be laid down. A custom must not be interpreted as a survival of something of which it cannot be a survival, and it must not be regarded as the survival of something, which is not known to have existed, or the earlier existence of which may not be assumed for some other reason, as for example in the so-called survivals of an ancient state of group marriage.

Nowadays the reaction against the evolutionary school of anthropologists has become so strong that any attempt to conjecture the origin of a social institution or of an element of culture has been pronounced to be out of place in social anthropology. It is, however, in this field that social anthropology has performed some of its most important tasks. Its results are to a large extent as well established as any reached in any sphere of research. The common complaint of the 'new anthropology' that the comparative method detaches the cultural phenomenon from the organic whole, of which it forms part, is largely due to the incompleteness of the sources at the sociologist's disposal, and can be remedied by careful monographs on particular cultures. The 'new anthropology' aims at discovering general laws, but it is doubtful whether such general laws, if discovered, would be of much service in investigating social phenomena.

---

* Substance of the Huxley Memorial Lecture for 1936, delivered by Prof. Edward Westermarck before the Royal Anthropological Institute on October 27.

On the other hand, the view expressed by Prof. Radcliffe-Brown that "no insight, however genial, can fully compensate for the absence of direct personal contact with the kind of material that the anthropologist has to study and explain", is to be fully endorsed. It is borne out by Prof. Westermarck's personal experience of nine years close contact with the Moors, spread over more than three decades, and spent in investigating their customs and ideas.

Morphogenesis and the Field Concept

THE discussion on morphogenesis which was held in Section D (Zoology) during the Blackpool meeting of the British Association was concerned mainly with the use of the field concept in experimental embryology. The central problem of the causal analysis of development is to account for the production of organs, that is to say, of masses of tissue which are integrated into units. Such integration can only be dealt with in terms of something which extends throughout the whole volume of the mass, and such extended entities are now usually referred to as 'fields'.

The first problem which arises is to give a satisfactory description of the integral behaviour. The sequence of shapes which are assumed by an organ during development has been described in great detail for most animal organs, but we require now some way of summing up, for each organ, the whole assemblage of shapes in a way which expresses the unitary character underlying the series. Probably a new branch of mathematics will be necessary to deal with such unfolding of even more complicated forms, though Dr. J. Needham mentioned the application of topological analysis and Gaussian curve analysis as hopeful possibilities. Mr. C. H. Waddington gave an example of what can already be attempted in some of the simpler cases ; the shape of the notochord and somites of the early chick embryo can be expressed as the product of two damped wave functions, with the time variable in the expression for the damping of the longitudinal wave function, so that as time proceeds more waves (that is, somites) are formed. It is possible, by causing the embryonic body to develop in a bent form, to distort the co-ordinate network in which the functions are measured, and experiments of this kind may make it possible to choose, from mathematical possibilities, the particular formulation which most immediately expresses the actual forces at work.

The integrated or organized behaviour of developing organs is shown by the regulation of parts of the organ to reconstitute the whole ; such experiments make it clear that the behaviour of a part of a developing organ is a function of its position in the whole. Dr. P. D. F. Murray described some beautiful examples of this type of behaviour, taken from his own earlier work on chorio-allantoic grafts of fragments of the limb-bud of chick embryos, and from Miss H. B. Fell's recent work on tissue culture of the same material. Thus if the isolated fragment contains slightly more tissue than would normally take part in the formation of the femur, it nevertheless forms no more than a complete femur, which therefore incorporates the extra tissue. Dr. Murray also discussed the mosaic development of later stages in which regulation is no longer possible. Prof. E. A. Spaul's interesting and important communication on the hormonal control of metamorphosis in Amphibia also dealt with aspects of morphogenesis which do not come into the scope of this short note.

Regulation can only be analysed in ordinary causal terms if we suppose that the series of whole unit shapes, to which regulation occurs, is an equilibrium-series, that is, an equilibrium which is not constant but follows a definite course in time. According to this view, all the forces which at any time produce the developmental form-changes of an organ are in equilibrium with one another, and if the equilibrium is disturbed, for example, by removing part of the tissue, the same forces restore the equilibrium and thus cause the regulation of the organ. Regulation is therefore due to the interaction of forces proceeding from the different parts of the developing organ-rudiment. In so far as it is dependent on forces proceeding from different parts, it is dependent on local differences within the organ rudiment, and is in this respect similar to mosaic development, which is often and wrongly taken to be the exactly opposite type of behaviour to regulation. According to the present point of view, the differences between them are much less important ; both types of behaviour depend upon local differences within the developing mass, but in cases where regulation occurs these differences are still labile and are capable of being altered by their mutual interaction, while in the mosaic stage the differences have become fixed and stable.

Dr. Needham concerned himself mainly with the nature of the forces which are concerned in setting up such equilibria. He directed particular attention to the possibility of finding a basis for the structural differentiation of masses of tissue in the arrangement of anisomorphic micelles or molecular aggregates. We know both that such molecules exist in protoplasm and that they can be arranged into orientated masses of the nature of liquid crystals. Such facts make it possible for the biochemist to form a picture of what it is the embryologist may be referring to when he invokes a '*cytosquellette*' or an '*Intimstruktur*'. The time has not yet come, he said, for an attempt at a detailed application of such ideas. We want to know, in particular, something about the maximum size of the volumes which can be affected by such molecular structures. Can we expect the orientated arrangements to be large enough to be invoked as an immediate explanation of such phenomena as the closure of the neural plate or the gastrulation movements in an amphibian egg, or must we only expect to find them active as determining the positions of other agencies which are the immediate causes of the more large-scale changes of form ?

C. H. WADDINGTON

Dietary Standards

IN December 1935, a Commission of Experts (Technical Commission) appointed by the Health Committee of the League of Nations issued its London Report on the "Physiological Bases of Nutrition" (see NATURE, Feb. 1, p. 176). The publication of this report was followed by its communication for study to representative learned societies, social studies institutions and health administrations in various countries. Observations received from such sources indicated general approval of the purpose and content of the report. Several suggestions were made, however, regarding details which might deserve further consideration. These were examined at a further meeting of the Technical Commission at Geneva in June last, with the result that a revised edition of its report has now been published[*].

The most noticeable changes in the new edition are those which amplify the previous sections dealing with the feeding of children. The general principles of infant feeding are dealt with in greater detail. Such topics are now included as the use of heated milk to prevent milk-borne infections, the methods of preventing nutritional anæmia and the special requirements of premature infants. Dietary schemes are now included for children in the age groups 5–7 years and 12–14 years as well as for those in the younger groups. Incidentally, the energy allowances for children in the age groups 1–2 years and 2–3 years have now been slightly raised. A further alteration of note concerns the energy allowances for adults. It may perhaps be remembered that in the original report an allowance of 2,400 calories a day was suggested for men and women alike, with supplements for muscular activity varying according to the severity of the work performed. In the revised edition, the basal allowance is the same, but the supplements are increased, so that for light work the new scale allows up to 75 calories per hour of work in place of 50, for moderate work 75–100 calories in place of 50–100, for hard work 150–300 instead of 100–200 and for very hard work 300 calories and upwards instead of 200 and upwards.

Certain general principles regarding the choosing of suitable dietaries are set forth in greater detail in the new edition. The modern conception of 'protective' foods is elaborated; the term is defined as including foods which are especially rich in those nutrient principles (good protein, vitamins and minerals) in which the chief foods of any geographical area are deficient. Good protein might thus be a valuable protective food in an Asiatic diet but not in a Western diet where a scarcity of it is comparatively rare. Attention is directed to the value of lightly as opposed to heavily milled cereals as a source of iron and vitamin B_1, and to butter in preference to other common fats because of its richness in vitamin A. The consumption of excessive amounts of sugar is condemned for the reason that it tends to lessen the proportion of protective foods in the diet as a whole. Lastly, the Commission has added to its list of problems requiring serious study the investigation of the optimum amount of milk required by human beings at different ages.

[*] "Report on the Physiological Bases of Nutrition." Revised and amplified at the meeting held at Geneva, June 4–8, 1936. *Quarterly Bulletin of the Health Organisation, League of Nations*, 5, 391 (London: George Allen and Unwin, Ltd., 1936).

Educational Topics and Events

CAMBRIDGE.—The Vice-Chancellor gives notic that the professors of physiology (Sir Joseph Ba croft), social anthropology (Prof. T. C. Hodson) an zoology (Prof. J. Stanley Gardiner) are due to reti on September 30, 1937.

Prof. Th. Von Kármán, of the California Institut of Technology, has been appointed Rouse Ba lecturer for the year 1936–37.

The following have been approved for the degre of Sc.D.: W. L. Edge, of Trinity College, and D R. G. W. Norrish, of Emmanuel College.

At Clare College, E. N. Willmer, of St. John College, University lecturer in physiology, has bee elected into an official fellowship.

At Newnham College, the Henry Sidgwick Memoria Lecture will be delivered on November 28 at 5 p.m by Lord Rutherford. The subject of the lecture i "Modern Alchemy".

The Adams Prize is open to the competition of a persons who have at any time been admitted to degree in the University. Women are also eligibl The subject proposed for the period 1937–38 is th distributional properties of functions of statistic variables.

LONDON.—The following degrees have been con ferred: D.Sc. (Economics) on R. P. Tripathi, a internal student, of the London School of Economics D.Sc. on E. E. Jelley, an external student, and D.S (Engineering) on R. W. Bailey, an external studen

OXFORD.—W. D. Hambly, of Jesus College, ha been granted the degree of D.Sc. for his work i social anthropology.

Dr. J. A. Douglas has been appointed deputy f the professor of geology during the vacancy.

THE bicentenary of the University of Göttinge will be celebrated in the last week of June 1937.

THE International Congress on Technical Educatio which was to have been held in Rome on May 28–3 but was indefinitely postponed will take place ther on December 28–30. The Congress is under th auspices of the Bureau international de l'enseign ment technique, 2 Place de la Bourse, Paris, fro which further information can be obtained.

THE following scholarships, which are tenable f three or four years, according to the length of t course at the university selected, will be offered b the Institution of Naval Architects for competiti in 1937: *Naval Architecture:* Martell, £130 p annum; Trewent, £125 per annum; Denny, £75 p annum. *Marine Engineering:* Parsons, £150 p annum; Yarrow, £100 per annum; Denny, £75 p annum. Full particulars may be obtained from t Secretary of the Institution of Naval Architect 2 Adam Street, Adelphi, London, W.C.2.

ADULT education offers to a community sufferin from the lag of the social sciences behind the advan of the natural and technological sciences and threaten by consequent social disorganization a potent remedi instrument. It has, to use a metaphor populariz by Sir Josiah Stamp *a propos* of the "impact science" in his address to the British Association, a high potential value as a 'shock-absorber'. This has been recognized in the United States, and is one of six reasons assigned by Dr. Floyd W. Reeves, professor of education in the University of Chicago, for he recent rapid expansion in adult education in the United States, the other reasons, less significant and compelling, being: activities of the American Association for Adult Education, organized in 1926; ncreased leisure; need for retraining for new occupaions resulting from technological progress; Thorndike's exposure of the fallacy that adults rapidly lose ability to learn; and the success of a widespread drive to promote parent-education so as to facilitate the introduction of reforms in school-teaching methods, notably in methods of teaching how to read. Dr. Reeves is consultant and was director of personnel to the Tennessee Valley Authority, and he has contributed to *School and Society* (Aug. 29) a paper on adult education as related to the T.V.A. In the co-operative commonwealth administered by his body, its adult educational programme holds a key position. In the systematic employment in this field of four new instruments—the public library, radio, visual education and public affairs forums—the authority is pre-eminent among educational agencies. A three-weeks observational tour revealed great keenness among the learners, numbering more than 25,000, and a high standard of efficiency among the teachers, more than half of whom give their services without pay in their spare time. Concerning adult education in the country as a whole, Dr. Reeves quotes statistics indicating that the participants in 1934 numbered more than twenty-two million.

Science News a Century Ago

A Balloon Voyage from England to Germany

There were several notable balloon voyages in 1836, but none of them excited greater interest than that by Charles Green in the great Nassau balloon rom the Vauxhall Gardens to Weilburg, in the Duchy of Nassau, on November 7–8, 1836. The balloon had a full equipment of scientific instruments, provisions for a fortnight and an apparatus with which it was hoped to be able to keep the balloon afloat if it was necessary to come down on the surface of the sea.

With two companions, Green ascended at 1.30 p.m. on Monday, November 7, and landed at Weilburg at 7.30 a.m. on Tuesday, November 8. When he passed over Dover, a message for the Mayor was sent down in a parachute. Writing of the episode in the *Athenæum*, "W. P." said: "We look forward with some anxiety to the receipt of a more detailed account of this interesting adventure, the perfect accomplishment of which must have realized the most sanguine expectations of the gentlemen who undertook it. It is no matter of wonder that it should have excited the public attention with such a lively interest, for to say the least of it, it has furnished a fact which is quite new in the history of man—that of his having travelled a distance of from four to five hundred miles in the short space of eighteen hours, or in other words, having travelled, in that period, a distance which is not usually accomplished n six times as many hours".

The Human Brain

In a review in the *Athenæum* of November 12, 1836, of "The Human Brain, its Configuration, etc., illustrated by references to the Nervous System of the Lower Animals", by Samuel Solly, the writer said: "This is a scientific book by a scientific man, and written rather for the profession than the public. We hope, however, that every day will bring physiology more within the range of general education, and that future generations will know something more of themselves, physically as well as morally, than their ancestors did, in the ignorant past. . . . Hitherto as he himself firstly observes, the information conveyed of the anatomy of the brain, by systematic works, has amounted to little more than a vain catalogue of names, applied to parts, without reference to their structure, their functions, or even their analogies in the nervous system of the lower animals. . . . That Mr. Solly should have abandoned this method, and broken through a long night of ancient usage, to proceed in a truly scientific plan . . . is good *primâ facie* evidence in favour of his mental qualifications for the task he has undertaken; and his perpetual reference to comparative anatomy shows an equal contempt for the spirit of routine, which has so long possessed the medical constituted *corps* of London. . . ."

Samuel Solly (1805–71), the author of the book, had been trained under Benjamin Travers (1783–1858), surgeon to St. Thomas's Hospital, London, and was elected a fellow of the Royal Society in 1837.

Identification of the Body of Charles I

In a lecture on this subject delivered at the Aldersgate School of Medicine and reported in the *London Medical Gazette* of November 12, 1836, Dr. William Cummin gave the following account of the identification of the remains of Charles I, when a search conducted by Sir Henry Halford was made for them at St. George's Chapel, Windsor: "The particular vault in which the coffin was deposited had long remained unknown, though it was understood to be the one in which Henry VIII and one of his wives were laid. Accident led to its detection. A scroll with name and date served in some measure to authenticate the outer covering; but the examination of the head left not a doubt of the identity of the royal remains. Upon disengaging the face from the cere-cloth, which had been lined with an unctuous and resinous substance, apparently with a view to exclude the external air, the complexion of the skin was found to be dark and discoloured. The forehead and temples had lost little or nothing of their muscular substance; the cartilage of the nose was gone; but the left eye in the first moment of exposure was open and full, though it vanished almost immediately; and the pointed beard, so characteristic of the period of the reign of King Charles, was perfect. The shape of the face was a long oval; many of the teeth remained; and the left ear in consequence of the interposition of the unctuous matter between it and the cere-cloth was found entire. The countenance, in short, notwithstanding its disfigurement bore a strong resemblance to the coins, the busts and especially to the pictures of Charles the First by Vandyke. Finally the fourth cervical vertebra was found divided transversely—the corresponding surfaces being smooth, betokening that they had been separated by a heavy sharp instrument."

A. J. H. Goodwin: The Mpondo regimental system. An account of the regimental system of the royal houses of the Western Mpondo.

August 19.

J. A. Gilmore: Young's modulus for steel surveying bands. Steel bands hanging in catenary loops between supporting stands are employed in Jaderin's method of measuring base lines. An investigation into the technique of using bands in this way is being carried on in the Surveying and Civil Engineering Departments of the University of Cape Town. An extensometer was used for finding the elastic constants. For steel bands approximately 1/8 in. wide by 1/64 in. thick, the yield point occurred at a stress in the neighbourhood of 53 tons per square inch, while the ultimate stress was approximately 108 tons per square inch. The value of Young's modulus for the same steel was 28,000,000 lb. per square inch.

N. H. Roberts: (1) Some studies of 50 cycle wave-forms in insulation testing. An experimental investigation is described of the factors which influence the wave-form of a particular 30 kilovolt testing transformer. The tests show that, if the capacity of the load is limited, a reasonable amount of resistance regulation combined with the use of an induction regulator will yield reliable results except at the lower readings. A calibration based on a knowledge of the crest factor at all settings is necessary. (2) A device for the superposition and simultaneous delineation of two wave-forms on a single cathode ray oscillograph screen. The paper describes a device in which the two wave-forms are applied alternately, being interchanged 20,000 times per second, and in which the waves may be superposed. Transient phenomena may be studied, and slight differences in wave-form readily shown up.

G. J. Burrows and A. Lench: (1) Co-ordination compounds of cadmium with tertiary arsines. (2) Derivatives of zinc halides with tertiary arsines.

G. H. Halligan: The causes of ice ages. This is a critical review of the literature on the subject since the year 1864. The question is treated in a new way, the fundamental facts regarding geology, astronomy, oceanography, physics, geography and meteorology, which must be adhered to, being first stated, and the writings judged by the standard thus obtained. The main difficulties encountered are those due to the action and reaction of physical agents brought about by complete changes of atmospheric and oceanic currents, due to cosmical causes. It is believed that no salient fact has been brought forward which vitiates Dr. J. J. Croll's theory advanced in "Climate and Time" in 1890.

A. Bolliger: The reaction of creatinine with 1,3,5-trinitrobenzol, 2,4,6-trinitrotoluol, and 2,4,6-trinitrobenzoic acid. Until recently, picric acid was the only colour reagent available for the determination of creatinine. Then it was found that 3,5-dinitrobenzoic acid also gives a useful colour reaction with creatinine; now it is shown that 1,3,5-trinitrobenzol, 2,4,6-trinitrotoluol and 2,4,6-trinitrobenzoic acid react in a similar way. Trinitrobenzol and trinitrobenzoic acid give a red colour with creatinine in alkaline solutions. These reactions are analytically useful, while trinitrotoluol furnishes a colour reaction which is not sufficiently marked for such purposes. All these colour reactions of creatinine have been explained as the formation of organic molecular compounds.

H. Finnemore, Suzanne K. Reichard and Dorothy K. Large: Cyanogenetic glucosides in Australian plants (5). *Phyllanthus gasstroemii*.

G. J. Burrows and A. Lench: (1) Derivatives of zinc halides with tertiary arsines. Zinc halides were found to react fairly readily with phenyl dimethyl arsine, diphenyl methyl arsine and *o*- and *p*-tolyl dimethyl arsines to give crystalline compounds which were found to be deliquescent like the zinc halides themselves. The iodides were found to be the most stable. With the exception of the compound $Zn(PhMe_2As)Cl_2$, the compounds isolated contained one molecule of zinc halide co-ordinated with two of arsine. (2) Co-ordination compounds of cadmium with tertiary arsines. The authors describe compounds formed by cadmium halides with phenyldimethyl arsine, diphenyl methyl arsine and *o*- and *p*-tolyl dimethyl arsine. The compounds are all crystalline, possessing characteristic melting points which decrease from chloride to iodide. With the exception of $Cd(Ph_2MeAs)_2I_2$, in which two molecules of arsine are co-ordinated with one of cadmium iodide, all of the compounds isolated contained one molecule of arsine to one of cadmium halide.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, November 9

Royal Geographical Society, at 5.—N. E. Odell: "The Glaciers and Morphology of the Franz Josef Fjord".

University of Leeds, at 5.15.—Prof. A. M. Carr-Saunders: "Population Situation in England".*

Tuesday, November 10

Royal College of Physicians, at 5.—Dr. J. D. Rolleston: "The History of Scarlet Fever" (FitzPatrick Lecture).

Imperial College—Royal School of Mines, at 5.15.—Philip Rabone: "Modern Methods of Flotation" (succeeding lectures on November 17 and 24).*

Illuminating Engineering Society, at 7.—(Joint meeting with the Institution of Engineers-in-Charge at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, S.W.1).—E. W. Murray: "Factory Lighting and Accident Prevention".

Pharmaceutical Society, at 8.30.—Dr. Donald Hunter: "Industrial Toxicology of To-day".

Wednesday, November 11

Institute of Physics, at 8.—L. C. Nickolls: "Physics and the Detection of Crime".

Thursday, November 12

Royal Society, at 11 a.m.—Discussion on: "Chemical and Physical Basis of Pharmacological Action" to be opened by Prof. A. J. Clark, F.R.S.

British Science Guild, at 4.30—(at the Goldsmiths' Hall, Foster Lane, E.C.2).—Lord Rutherford: "Science in Development".*

Royal Aeronautical Society, at 6.30—(at the Royal Society of Arts, 18 John Street, Adelphi, W.C.2).—Dr. F. W. Lanchester, F.R.S.: "The Part played by Skin Friction in Aeronautics".

Friday, November 13

Royal Society of Arts (Indian Section), at 4.30.—Dr. J. H. Hutton: "Head Hunters of the North-east Frontier".

Society of Chemical Industry (London Section), at 6—(at the Institution of Civil Engineers).—Dr. J. W. Mellor, F.R.S., and A. T. Green: "Refractory Materials" (Jubilee Memorial Lecture).

Official Publications Received

Great Britain and Ireland

Imperial Agricultural Bureaux. Herbage Publication Series, Bulletin No. 18: Pastures and Forage Crops in South Africa. Contributions by I. B. Pole Evans, A. R. Saunders, J. W. Rowland and S. R. de Villiers. Pp. 31+4 plates. (Aberystwyth: Imperial Bureau of Plant Genetics.) 3*s*. [1010

Technical Publications of the International Tin Research and Development Council. Series A, No. 44: Micro-Plasticity in Crystals of Tin. By Dr. Bruce Chalmers. Pp. 20. Free. Series A, No. 45: The Retarding Effect of Stannous Salts on the Oxidation of Olein and Oils. By Dr. Ir. S. H. Bertram. Pp. 10. Free. (London: International Tin Research and Development Council.) [2010

Survey of Thunderstorms in the British Islands. British Thunderstorms, containing Summer Thunderstorms. Fourth Annual Report, 1934. By S. Morris Bower and others. Vol. 2, Part 1. Pp. 48+viii+4 plates. (Huddersfield: Thunderstorm Census Organization.) 2*s*. 6*d*. [2110

Society for Preservation of Old Sheffield Tools. A Glossary of Words and Dialect formerly used in the Sheffield Trades. Part 1. Compiled and edited by B. Ronald Dyson. Pp. 56. (Sheffield: Society for Preservation of Old Sheffield Tools.) 1*s*. 3*d*. [2210

Other Countries

Académie des Sciences de l'URSS. Travaux du Congrès Jubilaire Mendeléev. Vol. 1. Pp. v+666+16 plates. (Moscow et Leningrad: Académie des Sciences de l'URSS.) [1910

Outlook of Professional Organizations

PROFOUND changes in manufacturing technique and industrial organization have resulted from the modernization of industry under the influence of power production during the last twenty years. This is generally recognized, but equally important changes in the personnel of industry have largely escaped attention. The recent report of the Industrial Health Research Board, it is true, pointed out that industry is demanding a different type of worker, but apart from Prof. Carr-Saunders' and Mr. P. A. Wilson's study of the professions, the increasing importance of the technical and scientific worker in industry has scarcely received the attention it deserves. Not only have the technical and scientific staffs been immediately responsible for much of the development and reorganization involved in the modernization and rationalization of industry, but they have also assumed an increasing share of the responsibility for the administration of the larger industrial units characteristic of to-day. In fact, large-scale industry mainly depends on their activities, and in turn they find in it the fullest scope for their knowledge and skill.

The rise of virtually a new professional class or type in this way is one of the most significant results of the modern technique in industry and commerce ; and its social consequences have as yet been given little attention. Certain of these questions are considered in a paper by Mr. S. W. Smith on the place and function of the administrative and technical worker in the new forms of economic structure, presented to Section F (Economic Science and Statistics) at the British Association meeting at Blackpool. One of the most important of these changes is the way in which the functional and professional outlook in the direction of industry is replacing the purely speculative or profit-seeking motive.

This growing power of the vocational outlook is of fundamental importance in the adaptation of industry, and indeed of society to meet new conditions. In so far as industry and commerce are directed less by self-interest than by the spirit of trusteeship or stewardship and service, the dangers of exploitation and social friction tend to diminish. Moreover, the type of control required in industry to-day involves leadership rather than domination, without sacrificing authority ; discipline based on intelligent co-operation, and decision reflecting the ideas of trained personnel acting freely and willingly in unity rather than the arbitrary will of a functional head.

That in certain public utility corporations the directors should, contrary to prevailing practice in limited companies, be debarred from any holding of shares, so as to secure that their dominant concern should be with the public interest, is only one example of the way in which a sense of duty and responsibility is replacing purely financial or private interests in the conduct of large undertakings. Moreover, the professional man, whether engaged in administrative work or not, finds his chief interest, when reasonably paid, in his work for its own sake ; and while the professional ideal continues to pervade the control of industry, so we may expect to find the service motive increasing in influence, and professional pride in the proper and efficient conduct of business organizations strongly reinforced.

This in itself should facilitate the wider outlook which to-day is essential in the integration of society to meet the impact of science. Industry can no longer be conducted solely with reference to its own internal efficiency and economy. It has to be considered in relation to society as a whole, and the technical ideal of fitness for a purpose must be applied in even wider spheres. No longer can we be content with a purely financial or even physical concept of the principle of economy. Social and human values are equally concerned, and industrial efficiency to-day involves the consideration not merely of chemical and physical processes but also of industrial health, psychology and the repercussions of a development on the community. What the product and process contribute to the worker and to the community are as important as what the worker contributes to the product.

The entrepreneur spirit alone is entirely inadequate to deal with such a situation and the creative forces involved. On the other hand, those scientific and technical workers whose administrative capacity and technical knowledge have placed them in such positions of trust have not invariably proved equal to the moral responsibilities involved. To this, particular attention was directed in Prof. W. Cramp's forceful address to Section G (Engineering) at the British Association. While the legal liabilities of the engineer and the loss of prestige attaching to faulty design or workmanship are the final safeguard to the community against abuse of privilege, standards of professional conduct are not infrequently honoured in the breach rather than by observance under the stress of commercial conditions.

For this, two factors may be regarded as primarily responsible. In the first place, as the instances cited by Prof. Cramp show, there is the absence of a scale of values firmly accepted by technical and scientific workers and so established by training and tradition that violation almost inevitably involves disqualification from practice. In part, this is a matter of education ; in part, a question of organization. One of the main motives, in fact, in attempts to raise the status of the chemist or the engineer by establishing a legal register and closing the profession has been that of safeguarding the public from the dangers attending a low standard of professional competence or integrity.

In the second place, the disregard of professional standards of rectitude is often due to the absence of a professional organization strong enough to afford its members adequate support in the face of economic or other forms of pressure from any source which tempts them to disregard the accepted ethical code. Nothing is more important to-day than that professional workers, whether within the ranks of science or not, should give their primary loyalty to their professional or vocational associations, and not to commercial or industrial organizations. It is only as they find in vocational organizations their permanent anchorage and shelter that professional workers can hope to make their full contribution to the shaping of organizations into instruments for the service of society and not for its mastery or exploitation.

This is indeed our crucial problem. The same factors that have increased the numbers of technical and professional workers have diminished their economic security and undermined their independence. The incidence of unemployment among their ranks on a scale undreamed of, in a class which was before the War virtually immune, has made efficient and effective professional associations essential if the full independent contribution of the professional worker is to be secured. The last fifteen years or so have witnessed a remarkable increase in the establishment of protective associations among such workers, and already an appreciable number of such organizations have negotiated collective agreements or enjoy the benefit of Whitley councils.

As yet, however, there have been few signs that such professional associations have recognized the wide orbit of their social responsibilities, nor have many of them yet advanced to a stage when they can afford a standard of professional protection commensurate with the pressure which industrial organization to-day could bring to bear if it chose. Nothing is more important than that professional organizations should address themselves to this question and consider their real place both in industry and in society to-day. Only as the professional worker gains his full independence can he make his decisive contribution to the shaping of society. Only, however, as he realizes the magnitude of that contribution is he likely to constrain the multiplicity of professional associations which at present prevents professional unity, for example, among chemists, from acting together in some way adequate to afford the members of the profession the necessary full protection.

The question of the responsibility of scientific workers for the prostitution of scientific effort for purposes of warfare, to which such repeated attention has been given of late, is only a special but rather difficult case. It is the absence of an association of scientific workers with any effective professional code, and the weakness of the professional ties between scientific workers in different countries, which debilitate any action by scientific workers at present. While, however, for the present it is rather as individual citizens than professional men that chemists and scientific workers in general can throw their weight into the scale against the tendencies which are dragging science and civilization down and debasing our heritage of intellectual and spiritual values, the recoil from the present abuse of scientific knowledge should surely inspire some determined effort to organize professional associations.

No thoughtful person can be blind to the dangers which the present abuse of scientific effort offers to science itself as to all that is best in our civilization. It is unthinkable that scientific workers should be so deluded or perverse as to make no attempt to preserve even the integrity of their own vocation. Towards this the first step is adequate professional organization. If that is undertaken in no mean spirit, but in a wide vision of the part which free scientific workers might play in the world of affairs, the petty loyalties and short-sightedness which in the past have prevented professional unity will surely disappear. Instead, we may see different classes of scientific workers, firmly established in their respective professional associations, presenting a united front and using their freedom to serve the community by shaping its organization in accordance with a nobler and wider concept of society. So, too, we shall find the sense of dependence and oppression which multiply so rapidly in the totalitarian State being lifted from the shoulders of men, and a measure of freedom, dignity and responsibility being given to them which once more shall prove the stimulus to creative thought, and add to the spiritual heritage of mankind.

World Population

World Population:
Past Growth and Present Trends. By A. M. Carr-Saunders. (Published under the auspices of the Royal Institute of International Affairs.) Pp. xv+336. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 12*s*. 6*d*. net.

THE public is being very well provided with information on the admittedly important subject of population; its growth and possible decline; its age constitution and the changes of that factor; the probable lengths of our lives; the social causes and effects of changes in the birth- and death-rates; migration and the future of the European races. Quite recently there have appeared several important works in English dealing with these matters, or some of them, such as, "Length of Life, a Study of the Life Table", by Dublin and Lotka; "The Measurement of Population Growth", by R. R. Kuczynski; "The Struggle for Population", by D. V. Glass, and now the important book under review.

Prof. Carr-Saunders is one of our most distinguished authorities on the subject. He was early in the field with his well-known study, "The Population Problem", which was published fourteen years ago and is still a mine of useful information. His new book is presented in a more popular guise and brings the facts up to date. These fourteen years have seen a great increase in the interest of the public in all population questions. One can scarcely take up a newspaper without seeing in it some letter or article on population. It is clear that the public in most Western countries is alive to its importance. There is evidence of this not only in the columns of the Press, but also in the foundation, some nine years ago, of the International Population Union and its constituent body in Great Britain, the British Population Society; in the various congresses that have been held in Geneva, in London, in Berlin; in the announcement of the Population Congress which is to take place in Paris next year; and quite recently, in the appointment, by the Eugenics Society, of a committee to investigate the fall of the birth-rate in Great Britain. All this apparatus, and the books mentioned above, will serve to keep the public provided with reliable information about these vitally important, and, in certain aspects, difficult matters.

In the author's own words, his book "attempts, though very briefly, to reconstruct population history and to describe the present population situation." He naturally begins with some account of the sources of information, and describes the early enumerations for special purposes, the sixteenth century ecclesiastical registrations of baptisms and burials, the first satisfactory French census of 1821, the English census of 1841, and so on. Also he points out that accurate migration statistics, which would require international co-operation, are still sadly to seek.

Two chapters are devoted to a discussion of the growth of world population, and we are given three independent estimates for the present day, the figures varying from 1,988 millions to 2,028 millions, so that the man in the street will be inclined to accept the round figure 2,000 millions, though this may be considerably in error. The chief source of error is in the estimate for China. "Upon any computation Asia holds over half of the world population from 1650 onwards", and "Europeans outside Europe are spread thinly"; there are, in fact, only about 200 millions of them.

After a simple discussion of the natural increase due to the difference between the crude birth- and death-rates, we come to an important chapter on the measurement of the true death-rate. This is arrived at by considering the chance that an individual of specified sex and age will have of surviving for one year. As pointed out by Dr. R. R. Kuczynski, whose valuable work in clearing up this and other population questions deserves all recognition, 'the expectation of life' derived from the 'life table', constructed from the actual data of age constitution and deaths, gives the only satisfactory criterion of mortality. Thus, if, as at present, the expectation of life at birth in New Zealand (mean of both sexes) is 66·46, then the death-rate in a stationary population with this expectation would be the reciprocal of this figure multiplied by 1,000, namely, 15·0. Figures derived in this way are strictly comparable, whereas 'crude' or 'standardized' rates are not.

We pass to the question of birth-rates. Crude birth-rates have no value as guides to the future or as the means of comparing the vital statistics of one country with those of another. In accordance with the method of Dr. Kuczynski, we must find out how many future mothers a thousand mothers will give birth to. It appears from Dr. Kuczynski's calculations that the net reproduction-rate for England and Wales, for 1933, was 0·73; for France, 0·82. The author remarks that "The only saving of life which can affect the trend of population is the saving of the lives of women before the end of the child-bearing period". This does not give much hope of improvement by means of a decrease in the death-rate, and if the net reproduction-rate is to be raised, the size of the family must be increased. This is the principal theme of the book in some of its later chapters. A table is given of the estimated future populations of various countries, on certain assumptions, including the well-known calculations of Dr. Enid Charles. We may take it as reasonably certain that the population of Great Britain will shortly reach a maximum, will diminish by some millions during the next generation, and may decline rapidly thereafter.

In this wise book there will be found statements of many intricate allied questions, judiciously treated. Such questions as the relation between over-population and unemployment; the effect of emigration on population; the desirability, or otherwise, of a reduction of our numbers at home. There are those who think that no harm would be done to Great Britain if the population were to come down by some few millions, provided that the downward acceleration could then be arrested. Some of these are matters upon which a general agreement is scarcely to be expected. But, whatever our opinions, we shall all value the clear presentation of these and many other difficult problems in Prof. Carr-Saunders's admirable work.

C. F. C.

The Phases of Berkeley's Idealism

George Berkeley:
a Study of his Life and Philosophy. By Prof. John Wild. Pp. x+552. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1936.) 25s. net.

IN this imposing volume, which fittingly emanates from Harvard, the author proceeds on the obviously sound principle that Berkeley's own wish should be respected, and his philosophical writings be read in the order in which he had published them. It is now generally recognized that there are two lines of thought running through Berkeley's theological idealism, which scarcely admit of being brought together in coherent fashion. On one hand, Berkeley preserved in his earlier writings, at least, a large portion of the empirical theory of knowledge; and, on the other hand, there gradually emerged in his later writings a conception of mind and of our ways of knowing mind that cannot be so much as stated in terms of the empirical theory.

The earlier phase of Berkeley's philosophizing, which Prof. Wild christens 'spiritism', 'psychologism', or 'subjectivism', leads, he insists, inevitably to 'solipsism'. It is, he conceives, to be traced back to an uncritical acceptance of Locke's causal metaphysics (p. 119). While disposing of the concept of material substance, Berkeley yet inconsistently hypostatized or reified the self into a self-existent substance; while refusing to allow that physical things are efficient causes, he yet inconsistently assumed the self to be an efficient cause, and thought of God as, in like manner, an efficient cause.

There are certainly difficulties enough in Berkeley's position, but I am by no means convinced that they are of the kind just specified. After all, the term 'substance' is excessively ambiguous, and by a 'spiritual substance', it was repeatedly asserted in the "Principles", is meant a thinking, active being, distinguishable from the inert objects of which it is apprehensive. Whether Berkeley's argument to prove that the *esse* of sensible things is *percipi* is successful may well be questioned; but I see no ground for the contention that this argument is inconsistent with his view of individual minds or spirits. Moreover, surely Berkeley is altogether misinterpreted when he is represented as having held that conscious minds can exist in abstract isolation from all objects, that these minds can will without willing anything, and perceive without perceiving anything (for example, p. 38)—a doctrine against which he was, in fact, never weary of protesting.

The later phase of Berkeley's speculation, as Prof. Wild pictures it, culminates in a transcendentalism, according to which the system of consciousness is not to be identified with an individual consciousness, but with a consciousness that includes in one system not only all empirical objects but all empirical selves as well (p. 174). Through this concept of a transcendent 'intelligible world' Berkeley was enabled, so it is maintained, eventually to grasp, to some extent, the nature of the 'world of becoming'; and at last in "Siris" (published in 1744) to construct a system of philosophy in the strict sense of the word. Primarily through Plato he came to appreciate the significance of the 'intelligible world'; and from the Neo-Platonists he learnt not only the meaning of transcendence but also, as a consequence, the meaning of philosophy itself as a revelation of the structure of the whole of being. But, it is argued, in a sense "*Siris* was always present to Berkeley's reflection, from the rude intuitions of the *Commonplace Book* to the strict methodological queries of the *Analyst*" (p. 422, cf. pp. 68–9).

For this statement I can find absolutely no warrant. I agree that it is a mistake to look upon "Siris" as exhibiting an entire break from the position of the early writings, but I fail to see in the latter any indication that Berkeley was then influenced by Neo-Platonic thought. Also, I confess there does not seem to me to be in "Siris" itself the definite metaphysical system which apparently Prof. Wild has discovered imbedded there; at the most, I should say, there are but vague hints as to the form which such a system might presumably take. Admittedly "Siris" is "so full of ancient lore that it is difficult to discern how much is Berkeley and how much is Plato or Plotinus" (p. 500); and I cannot but think that Prof. Wild has been reading into "Sirus" a great deal that is not really there.

A further contention calls for notice. Prof. Wild is assured that in the "Three Dialogues", which appeared in 1713, three years after the publication of the "Principles", Berkeley perceived for the first time "the total indefensibility of the causal subjectivism" (p. 162), on which he had been proceeding; and, particularly in the third *Dialogue*, by introducing a system of eternal 'archetypes' in the Mind of God, and by regarding the finite mind as 'dependent' (p. 183 *sqq.*), he was virtually abandoning his 'spiritism'. But, again, the reasoning does not convince me. For one thing, the notion of 'archetypes' in the Divine Mind meets us already in the "Principles" (for example, § 99), and in the "Principles" also the finite mind is throughout regarded as 'dependent' (for example, § 149). Furthermore, in the third *Dialogue* the 'archetypal' ideas are expressly stated to be ideas of 'things', or 'objects', and are, therefore, quite other than the Platonic 'ideas' or 'forms' referred to in "Siris" (for example, §§ 335–8); the finite mind is still regarded as a "substance" that is "affected from without"; and the Supreme Mind is still conceived as "the powerful cause of my ideas". In "De Motu", published in 1721, there are indications that Berkeley had been diving into Greek philosophy; but it was, I take it, in Rhode Island and in Cloyne that his more detailed researches in that field were made.

I have dwelt chiefly on matters in regard to which I cannot follow Prof. Wild's lead. I will not, however, conclude without expressing appreciation of much of his work. His treatment of Berkeley's critique of the mathematics of his time is, for example, admirable, and makes it clear that the attack on the doctrine of infinitesimals was not without justification. So, too, his account of Berkeley's attitude to natural science in "De Motu" is both judicious and suggestive. Altogether, he has produced a volume for which students of Berkeley will be grateful. G. DAWES HICKS.

Examinations

(1) The Marks of Examiners: being a Comparison of Marks allotted to Examination Scripts by Independent Examiners and Boards of Examiners, together with a Section on a Viva Voce Examination. By Sir Philip Hartog and Dr. E. C. Rhodes. With a Memorandum by Prof. Cyril Burt. (International Institute Examinations Enquiry.) Pp. xix+344. 8s. 6d. net.

(2) Essays on Examinations By Sir Michael Sadler, A. Abbott, Dr. P. B. Ballard, Prof. C. L. Burt, Dr. C. Delisle Burns, Sir Philip Hartog, Prof. C. Spearman and Dr. S. D. Stirk. (International Institute Examinations Enquiry.) Pp. xii+168. 5s. net.

(London: Macmillan and Co., Ltd., 1936.)

THE important part played by examinations in the modern world, not merely in educational, but also in social organization, amply justifies the attention that is at present being directed to the manner in which they function. The International Institute Examinations Inquiry, initiated and financed by the International Institute of Education of Columbia University, has already done exceedingly valuable work in the investigation of some of the more fundamental problems involved; and recent reports published by the French, the Scottish and the English delegations present the results of such investigations. The two books under notice represent part of the labours of the English delegation.

If we assume that examinations are a useful and even necessary part of social and educational machinery, there are two main things we wish to know about the examinations we employ. We wish to know, in the first place, to what extent their results may be taken as valid, and, in the second place, in what measure they are reliable. Validity and reliability are, in fact, the two essential characteristics which examinations must possess in order to perform adequately their social and educational functions. How far do examinations test that which they are designed to test, and how far can the results of an examination be relied on as an accurate measurement of what it measures? The recent report issued by the Scottish delegation—"The Prognostic Value of University Entrance Examinations in Scotland"—is concerned mainly with the answer to the first of these questions; a report of the French delegation, and also "The Marks of Examiners", issued by the English delegation, with the answer to the second.

Validity and reliability are only partly independent of one another. It is clear that an examination may have high reliability and low validity, though it cannot have high validity with low reliability. That is to say, an examination may measure a capacity or acquisition x with great accuracy and reliability, but the measurement of x may be partially or wholly irrelevant to the real purpose of the examination. If, however, the measurement of x is highly unreliable, it does not matter whether this measurement is irrelevant to the purpose of the examination or not; the examination can obviously have no validity. While, therefore, validity is probably the more fundamental characteristic, the investigation of the reliability of an examination would appear to be logically prior to the investigation of its validity.

A detailed account of an investigation by the English delegation into the reliability of the marking of examination papers is given in "The Marks of Examiners". The main findings had already been made public in "An Examination of Examinations", published in 1935, and these findings were then regarded with rather mixed feelings by all who had to do with school or university examinations. The investigation covers all the main types and grades of English examinations, and one and all are shown to be unreliable to an alarming extent, when we consider how much may depend upon them.

In some cases the methods of investigation may be open to rather damaging criticism. For example, in the case of the School Certificate papers in Latin and in history, fifteen scripts to which exactly the same average mark had originally been assigned were submitted to a number of different experienced examiners for remarking. In such a case it is obvious that the whole suggestion of the situation is to distribute the marks—the examiners were all ignorant of the original marks assigned—and consequently chance was bound to play a large part in the distribution. Hence we should expect to find great discrepancies between the marking of the different examiners. Even setting aside, however, all cases where the findings are open to criticism of this kind, the mass of evidence is overwhelming for the conclusions which the investigators draw, and the one question with which we are left is: What are we to do about it?

Another side of the international investigation is represented by "Essays on Examinations". This is a collection of papers by different authors on different aspects of English examinations. The work is more limited in its appeal—it is relevant mainly to English education in the narrow sense—and less important than "The Marks of Examiners". At the same time, it contains a very valuable historical account of the development of the scholarship system in England, from the pen of Sir Michael Sadler. This occupies almost half the book. There are also valuable papers on different aspects of the examination problem by Delisle Burns, Burt, Spearman, Ballard, A. Abbott, and Sir Philip Hartog. An account of the Leaving Examination in Germany, before the War, and under the Nazi regime, is appended. The short paper by Delisle Burns on "Examinations and the Social Needs of the Modern World" breaks new ground in the discussion of our examination system. This is an aspect of examinations demanding the most careful consideration, and it is an aspect which has up to now been largely neglected. The whole book leaves one with the impression—and the same is true of "The Marks of Examiners"—that the problems set to modern society by the role examinations have come to play are many and formidable, and the solution of these problems urgent. J. D.

Astronomy for All

(1) Stars and Telescopes

By James Stokley. Pp. xiv+319+33 plates. (New York: Harper and Brothers; London: Hamish Hamilton, Ltd., 1936.) 10*s*. 6*d*. net.

(2) Through the Telescope:

a Story of the Stars. By Prof. Edward Arthur Fath. Pp. vii+220. (New York and London: McGraw-Hill Publishing Co., Inc., 1936.) 10*s*. 6*d*.

(3) Highlights of Astronomy

By Prof. Walter Bartky. Pp. xiii+280. (Chicago: University of Chicago Press; London: Cambridge University Press, 1935.) 11*s*. 6*d*. net.

(1) THE Zeiss planetarium has done much to stimulate interest in astronomy, and it is much to be regretted that Great Britain does not yet possess one. Mr. Stokley, the director of the Fels Planetarium of the Franklin Institute, Philadelphia, has found that visitors often ask for the name of a book for study. To meet this demand he has written this volume. It contains a historical account of the development of astronomical thought and ideas from the earliest times, with a survey of the present knowledge about the solar system, stars and galaxies. The evolution of the telescope from its invention to the present time is described, and directions are given for assisting the amateur to construct his own telescope.

The book is not written for the busy layman who wishes to become familiar with the general trend of modern astronomical investigation, but it can be thoroughly recommended to the amateur who wishes to make a more detailed study of the subject. There is an excellent series of 33 plates which, instead of being scattered throughout the text, are collected together so that any particular plate is easily found.

(2) In this book, the reader is taken on an imaginary visit to the two large American observatories on Mount Hamilton and Mount Wilson, to see their instrumental equipment and to view different objects in the heavens. This provides the opportunity to describe some of the largest telescopes now being used in solar and stellar research, and to recount some of the main facts and the more interesting theories of the astronomical field of the present day. The role is that of the sightseer rather than that of the student, so that the book is mainly descriptive and the theoretical portions are brief.

The author endeavours to include no more than could be read in one evening by a reasonably rapid reader. Written for the unscientific reader, the book should help to stimulate interest in astronomy. The illustrations are numerous and well chosen; the reproductions of astronomical photographs are excellent.

(3) This book may be described as an elementary text-book that is different from other text-books. It has been written for the astronomical portion of the introductory general course in the physical sciences at the University of Chicago. This course is one of the four introductory courses of the new undergraduate curriculum, designed to give the student a general educational background before he ventures to specialize in any particular field. The ideas are presented in a novel and entertaining way; but to obtain the 'highlight' effect, there is often slipshod and inaccurate statements. Thus, for example, "It is gravity, that invisible force between masses, which causes us to drop and smash crockery and fall downstairs and which compels the earth to move as it does".

The author has used considerable ingenuity in describing the geometrical ideas of spherical astronomy without the use of geometry. The formulæ of spherical trigonometry required for connecting hour angle, declination, latitude, altitude and azimuth are sidetracked by the use of two charts; these enable many problems to be solved with an accuracy of about 2°.

The greater part of the volume is occupied with the geometrical ideas and with a description of the members of the solar system. The stars and the sidereal universe receive fewer than forty pages. In night study of the skies, an instrument called a 'stellarscope' has been designed for use in conjunction with the book. The stars and constellations are viewed on motion picture film so that, by superimposing each individual film upon the appropriate portion of the sky, the exact identification of the stars is made more readily than with a star atlas.

The book is well illustrated with line drawings and photographs; many of the drawings (by Mrs. Chichi Lasley) are arresting, attractive and amusing.

Radio Communication and Short Waves

(1) Principles of Radio Engineering

By Prof. R. S. Glasgow. (Electrical Engineering Texts.) Pp. xii+520. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 24*s*.

(2) Short Wave Wireless Communication

By A. W. Ladner and C. R. Stoner. Third edition, revised and enlarged. Pp. xvi+ 453+11 plates. (London: Chapman and Hall, Ltd., 1936.) 21*s*. net.

(3) Physik und Technik der ultrakurzen Wellen

Von Dr. H. E. Hollmann. Band 1: Erzeugung ultrakurzwelliger Schwingungen. Pp. ix+326. (Berlin: Julius Springer, 1936.) 36 gold marks.

ADVANCES in the science and practice of radio communication lead to a continual supply of new books dealing with various phases of the subject. Some of these are of the nature of monographs describing in detail the technique of a particular application of communications, while others set out in revised form the fundamental principles of the subject and of the various new devices which mark the lines of progress.

(1) Prof. Glasgow's book is based upon a lecture course given for some years at the University of Washington, and the logical development of the subject, with the clear but concise style, bear evidence of the author's experience as a teacher. The more interesting part of the book begins at Chapter vi with the fundamental properties of vacuum tubes and is followed by others in a natural sequence, dealing with amplification at audio and radio frequencies, oscillation, modulation and detection. The last hundred pages of the book are devoted to a brief but adequate study of aerials, including those designed for low-angle radiation, and also to a summary of existing knowledge of radio wave propagation.

The whole work is a really up-to-date exposition of the subject, and numerous references to recent publications are made throughout the book. The bulk of these references, however, are to papers published in the United States, and little mention is made of work in Europe. With this minor criticism, the book can be thoroughly recommended to all serious students of radio engineering.

(2) Most engineers and experimenters in the field of short-wave wireless communication are familiar with Ladner and Stoner's book, and the fact that a third edition has become necessary in about four years from the original publication is evidence of the popularity of the work. In this edition, much of the original text has been revised and some of the chapters expanded to deal with advances in all phases of the subject.

A new chapter on "Commercial Wireless Telephone Circuits" has been added, to deal with the practice in this field, which was insufficiently stabilized to warrant description in previous editions. Separate chapters are devoted to such subjects as modulation and constant frequency oscillators, which are not necessarily confined to short waves, but their inclusion makes for completeness in a book which is likely to continue to be in great demand by all those working in the wide and growing field of short-wave wireless communication.

(3) Dr. Hollmann's monograph is a detailed account of recent research on the various methods of producing electrical oscillations at frequencies corresponding to wave-lengths from a few metres down to a few centimetres. After chapters dealing with the production of such oscillations by spark excitation and by valve retroaction, about 120 pages are devoted to the positive grid type of electronic oscillator, and about half this space to the application of the magnetron valve to the problem. An appendix containing nearly 300 references indicates the vast field of literature covered, and this should help to make the book useful as a work of reference to specialists and research workers in this subject. R. L. S.-R.

Language, Truth and Logic

By Alfred J. Ayer. Pp. 254. (London: Victor Gollancz, Ltd., 1936.) 9*s*. net.

THIS excellent compendium of the views and doctrines of the new positivism derived from the scientific empiricism of the Vienna circle and an extreme interpretation of the aims of logic, will no doubt rejoice the increasing number of thinkers who have discovered lately that there is no philosophy at all. Carrying to its limits the methodological scepticism of Hume, the new positivism holds that sense-data are the primary elements of science, from which things and forces are its highly probable inferences. But as regards metaphysics, it should be put out of the way at all costs. Indeed, the imaginative and constructive functions of philosophy must give way entirely to its analytic function: thus the only real aim of philosophy is to get the propositions of science clarified and self-consistent.

The enthusiasm with which the author develops these points is evidence of the strength gained in Great Britain by these new theories. It should be pointed out, however, that such aims make the business of philosophy appallingly incomplete and uninspiring. For if sense-perceptions are the elementary data of knowledge, there are also intuitions of values and of general principles which are just as real facts as are the sense-perceptions themselves. The greatness and interest of philosophy consist in trying to harmonize such intuitions with sense-perceptions, and thus to give an adequate and systematized picture of experience as a whole. Jokes and jibes may enliven a discussion; but they cannot command an intelligent assent, especially when they are aimed at time-honoured values which are mainly responsible for the existence of philosophy, and also of logic, as such. T. G.

Jouannet:

Grand-père de la Prehistoire. Par Dr. André Cheynier. Pp. 101+3 plates. (Publiés sous les auspices de la Société Historique et Archéologique du Périgord.) (Brive: Chastrusse, Praudel et Cie., 1936.) 15 francs.

FRANÇOIS-RENÉ-BENIT VATAR, SIEUR DE JOUANNET (1765–1845), a native of Rennes, who settled in Périgord in the early years of the Revolution, is here celebrated as a forgotten pioneer in the study of prehistoric archæology, and a precursor of Boucher de Perthes. In 1810, while investigating a Gallo-Roman cemetery near Périgueux, Jouannet discovered a neolithic station, which there is reason to believe is the first ever described. As the author shows by dated references, Jouannet was first in the discovery of palæolithic caves and of a Solutrean site, as well as of the association of worked flints with fossilized animal remains. He was also the first to classify antiquity into stone, bronze and iron ages, and to distinguish two phases of the stone age. In experimenting in working flint and in analysing chemically fossil bones and bronze axes he initiated scientific methods of archæological investigation. His reports, which were submitted to local scientific academies or appeared in the Dordogne Calendar, are here reprinted with an account of his career.

Eclipses of the Sun

By Prof. S. A. Mitchell. Fourth edition, revised and enlarged. Pp. xvii+520+81 plates. (New York: Columbia University Press; London: Oxford University Press, 1935.) 25*s*. net.

PROF. MITCHELL's book on eclipses of the sun is so well known that detailed notice of the new edition is not necessary, the more so because it differs from the third edition only by the addition of a new chapter dealing with the eclipses of 1932 and 1934. A few minor additions have been made, but there has been no general revision. It is odd to read, in a volume bearing the date 1935, a passage such as this: "The author is going to be rash enough to predict that the 1932 corona . . . will show the minimum type of corona". There are a number of other passages which should have been revised. It would perhaps have been better if the results derived from the observations at the recent eclipses had been given as an appendix.

Although the excellent work of Lyot, at the high-altitude station at the Pic du Midi, is for the first time making it possible to study the corona when the sun is not totally eclipsed, it seems probable that astronomers will continue to be dependent upon observations at times of total eclipse for the solution of many solar problems. Prof. Mitchell's treatise remains the best and most complete account of the methods and results of eclipse observations.

Grundzüge der Vererbungslehre

Von Prof. Dr. Friedrich Alverdes. Pp. viii+143. (Leipzig: S. Hirzel, 1935.) 5 gold marks.

THIS is a simply stated introduction to Mendelian inheritance with a biological background. Early chapters deal with cell and nucleus, egg and sperm, fertilization, genotype and phenotype, race and species: "Unter einer Rasse verstehen wir eine Gruppe von Individuen (Pflanzen, Tieren oder Menschen), die in ihren wesentlichen Erbanlagen übereinstimmen". The Mendelian laws are expounded, as well as sex determination, recombinations, linkage, and the basis of these phenomena in the chromosomes. The last two chapters give a short survey of heredity in man. The account is clear but occasionally over-simplified, as in the statement that there are two pairs of factors for eye-colour and three for skin-colour in man.

The Psychology of Human Behavior

By Prof. J. H. Griffiths. Pp. xxi+515. (London: George Allen and Unwin, Ltd., 1936.) 12*s*. 6*d*. net.

THE author of "The Psychology of Human Behavior" is to be congratulated on the production of an extremely readable and well-constructed elementary text-book of psychology. The addition of questions for discussion at the end of each chapter is a most helpful feature and adds enormously to the value of the book from a teaching point of view. The supplementary readings at the end also of each chapter will prove a great help to those who wish to pursue their study of psychology further. This is one of the very best books on the subject.

Fibre Studies

EXCEPT in so far as Section A may regard all other sections of the British Association as subsidiary to the mathematical and physical sciences, the subject of fibre structure is by no means a prerogative of physicists sitting alone, and discussion to be most profitable is best conducted with the co-operation of one or more of the other sciences, such as chemistry and biology. This point was emphasized by W. T. Astbury in opening a brief symposium on fibre studies arranged for Section A at the Blackpool meeting of the Association, but his subsequent remarks, dealing with problems arising out of the long-range elasticity of many protein fibres, were addressed specially to physicists.

Certain natural protein fibres, in particular the hairs of mammals, are endowed with elastic properties of relatively enormous range. The effect is shown by X-ray and related studies to be due to combinations of polypeptide chain-molecules, normally in a regularly-folded configuration, from which they may be pulled out straight by the application of tension, and to which they return when the tension is released. By suitable modification of the state of cross-linkage of these polypeptide chains, both the elastic range and the driving force of elastic recovery may be varied considerably. Animal hairs, for example, may actually be contracted to a length only about half their natural length. Closely analogous, from both the X-ray and physical elastic point of view, to one of the modifications of the hair protein, ***keratin***, is the chief muscle protein, ***myosin***, and there is apparently some fundamental type of molecular fold common to both. The crystalline proteins, which are built from 'globular' molecules, have now also been shown to be based most probably on regularly-folded polypeptide chains. The latter are liberated from their special, and often highly specific, configuration by the change known as 'denaturation', the resulting insoluble mass being often highly elastic like keratin and myosin. X-rays suggest that this elasticity is again to be referred to groups of folded polypeptides which may sometimes be drawn out into straight chains, just as keratin and myosin may be so drawn out. By this means artificial protein fibres may be prepared from originally globular molecules.

The detailed interpretation of the deformation and unfolding of protein chain systems provides one of the most fascinating and difficult problems in molecular mechanics. At the moment, it seems to present two chief aspects: (1) Is the hexagonal fold postulated for keratin and myosin sound? (2) Is the keratin-myosin fold—whatever it may be—a fundamental fold for proteins in general?

Dr. J. B. Speakman, accepting the X-ray picture and intramolecular stress theory of keratin structure as substantially correct, proceeded to show how the many elastic modifications that arise when strained fibres are treated with various reagents can be simply explained in terms of the reactivity of the salt and disulphide cross-linkages of the keratin 'grid'. The reactivity of these linkages depends on their state of stress, which in turn depends on the configuration of the grid. In consequence, the properties of each type of linkage influence those of the remainder: thus the reactivity of the disulphide linkage in stretched hairs is frequently at a maximum under conditions in which the salt linkages are most stable.

The concept was illustrated by the results of numerous experiments in which the stretched fibres were submitted to the action at 50° C. of a series of mixtures of sodium sulphite and bisulphite, so chosen as to vary the *p*H while maintaining the reducing power. The extent of disulphide breakdown was then estimated by measuring the amount of 'permanent set' produced. It is a maximum at *p*H 5·95, where the salt linkages are most stable, and falls off rapidly on either side of this point as their stability decreases. The interpretation put forward by Speakman is that the dissolution of the salt linkages permits a configurational rearrangement which relieves the stress on the disulphide linkages and so reduces their reactivity. In the hands of Speakman, this chemical modification and 'playing off' of one linkage against another has proved exceedingly fruitful, and the properties of hairs so modified present features of unusual interest, whether for chemist or physicist.

The rather more pragmatic side of fibre research was emphasized by the contributions of Dr. M. Mathieu on "The X-Ray Cinematography of a Simple Fibre Reaction", and of Dr. E. Griffiths and J. H. Awbery on "Apparatus for Maintaining Constant Humidity". Mathieu introduced a new example of powerful X-ray tube with rotating anticathode, the latter being shut off from the atmosphere by nothing more elaborate than a ground cone, suitably lubricated with vacuum grease and under the control of an external adjustable spring to prevent 'seizing'. The rate of rotation possible with this system is not high—one or two revolutions per second—but it has sufficed to take one-minute photographs of the nitration of cellulose with gaseous nitrogen pentoxide, and so to follow the process step by step. The regularity of the original cellulose structure first disappears in the direction of the fibre-axis, until a stage is reached where there remain only equatorial reflections and the pseudo-period corresponding to the length of a glucose residue. The molecular chains then move farther apart and slide over one another so as to leave the effective residue thickness unaltered, whereupon the (101) reflection of nitro-cellulose appears. After this, little by little, the chains take up their final stable configuration and the characteristic fibre-period (25·1 A.) of trinitro-cellulose can be observed.

The whole experiment takes only an hour, and illustrates most strikingly the immediate advantages to be derived from the use of powerful X-ray tubes. Indeed, such tubes are rapidly becoming an absolute necessity. The study of unstable systems and of physical and chemical transformations, particularly those associated with life processes, still offers an enormous field to the structure analyst. We need X-ray cinematograph films of all these things. W. T. A.

Food Investigation: a Retrospect and the Future

THE reconstitution of the Food Investigation Board in the autumn of 1934 provided an occasion for a review of the work accomplished by the Board during the seventeen years of its existence and the determination of the lines along which further progress should be sought.* Not only have general solutions been found, in the gas-storage of fruit and chilled meat and in the brine-freezing of fish, for the three main problems with which the Board was faced when originally established, but at the same time great advances have also been made in the science that underlies the storage and handling of foodstuffs.

Although each animal product presents its own problems of handling and storage, yet, in the final analysis, these problems may be stated more generally as those of the properties and behaviour of proteins and fats, of pigments and micro-organisms. Thus, among the main subjects of investigation have been *rigor mortis* and glycogenolysis in muscle; the identity and physical chemistry of animal proteins; the freezing of colloidal systems and tissues; the chemistry of the pigments; the constitution of the animal fats; and the identification and characterization of the micro-organisms found on animal products. The Board now considers that it would be profitable to take up other lines of work as opportunity offers, the most important being the organic chemistry of the proteins. It is now known, for example, that the protein myosin controls the changes taking place in meat and fish during *rigor mortis*, as well as the structural changes that occur during storage: in the egg, the protein mucin is the important factor. Progress has been made in determining the general physico-chemical properties of the proteins, but further advances will depend upon an exact knowledge of the constituent amino acids and of their arrangement within the molecule. The results of such investigations will be of wide interest in chemistry, physiology and nutrition. The Board has therefore arranged for a member of the director's staff to spend a year in Prof. A. C. Chibnall's laboratory at the Imperial College of Science and Technology in order to gain experience of the specialized technique required, before undertaking research on this subject. It is also hoped to commence work on the identification of the autolytic enzymes of meat and eggs and the lipolytic enzymes of bacteria, to the action of which is often due the development of taint in animal foodstuffs. Although attention has hitherto been devoted chiefly to meat, the programme of research has now been widened to include both eggs and poultry, and the problems of their wastage and quality.

The handling and storage of fresh fruit present problems different in character from those of animal produce, since the material is living and not dead, and because the plants concerned belong to different orders and genera, and the parts used as foodstuffs comprise nearly all their chief organs. In spite of the work which has been carried out on the preservation of fruit and vegetables, the qualities after such periods of storage as are customary in commerce are, in general, inferior to those of the material at its best. The extension of control depends upon the advancement of our knowledge of the physico-chemical mechanism upon which the living processes are based. Up to the present, the Board has concentrated upon an intensive study of the respiration and metabolism of carbohydrate in the apple and potato. It is now including a study of the enzymes and the metabolism of nitrogen, and intends to investigate the metabolism of acid, the formation and breakdown of the cell wall and the nature and origin of the substances responsible for the development of colour, flavour and odour.

---

* Department of Scientific and Industrial Research. Report of the Food Investigation Board for the Year 1935. Pp. x+232. (London: H.M. Stationery Office, 1936.) 3s. 6d. net.

The Board points out the necessity of a close contact with commercial practice and describes the different steps taken to ensure the application of laboratory results in the trades concerned: thus a small laboratory is being established, in the vicinity of Smithfield Market, London, on the lines of the Covent Garden Laboratory (which is also being extended), to act as a centre for liaison with the trade. Similarly, arrangements have been made with Messrs. Crosse and Blackwell, Ltd., for the trial at Peterhead of a kiln for the smoking of fish, which is designed in accordance with the principles established at the Torry Research Station. The Board also co-operates with similar bodies in the Dominions and is stimulating research in other parts of the Empire, since it is usually essential that the problems of storage should be studied as soon as the produce has been prepared for the market, and this is not possible in Great Britain in the case of such important fruits as the orange and banana.

The report of the Board refers as usual to the changes which have taken place in its composition during the year: Prof. C. H. Lees and Sir Thomas Middleton have been appointed additional members. The Engineering Committee has been reconstituted with the following membership: Prof. C. H. Lees (chairman), Prof. E. H. Lamb, Prof. G. I. Taylor and Prof. H. E. Watson. The bulk of the report is devoted to the report of the Director of Food Investigation, Mr. E. Barnard, and is divided into sections dealing with meat, poultry and eggs, pork bacon and hams, fish, fruit and vegetables, canning and engineering. The researches at present in progress are described by the investigators who are carrying them out. One or two may be referred to here, to indicate some of the problems involved and the results obtained.

Two effects of the treatment of the pig immediately before slaughter on the quality of the carcass have been measured. First, fasting has been shown to increase the thickness of the flank. Secondly, the muscle of pigs overheated before slaughter has a higher electrical resistance than that of rested pigs; low resistance facilitates the penetration of salt during dry salting. Farm-killed pigs were found to have a low resistance as compared with factory-killed, and this difference was traced to the shaking which the carcasses undergo during transport to the factory.

Trials of the refrigerated gas-storage of Conference pears have been made with good results: flavour, texture and appearance are retained after long periods of storage. If soft fruits are given a preliminary heating, there is little loss of the power to set, during storage in the frozen state at − 7° C., a temperature which inhibits the growth of moulds, or during storage with sulphurous acid. Without the preliminary heating, the power to set in jam-making is more or less rapidly lost. Apples and plums, however, do not suffer this loss under the same conditions. It has been shown that the amount of ethylene evolved by ripe apples and bananas is sufficient to initiate the ripening of green, unripe bananas. The passage of air containing one part per million of ethylene over the green fruit also causes it to begin ripening after 24 hours, but with fruit that has just started to ripen the mixture has little effect. These experiments suggest that the efficiency of ripening rooms for bananas heated with coal gas burners may be due to a slight leakage of the gas supply permitting a low concentration of ethylene in the air surrounding the fruit.

The Upper Palæolithic in the Light of Recent Discovery*

By Miss D. A. E. Garrod

THE last twelve years have seen a new impetus given to prehistoric studies by the multiplication of researches outside Europe. Excavations in Africa, the Near East, Asiatic Russia and China have opened up a new field for speculation, and at the same time have revealed the unsuspected complexity of many problems which to De Mortillet and other pioneers seemed relatively simple. Gone for ever is the straightforward succession of Palæolithic cultures from Chellian to Magdalenian as laid down in the Musée Préhistorique. Even so early as 1912, when Breuil produced his classic paper on the subdivisions of the Upper Palæolithic, its foundations were sapped, and the discoveries of the last decade have merely completed its demolition as a system of world-wide application.

In the old system the Palæolithic cultures appeared as a straightforward succession with clear-cut horizontal divisions, as in a diagrammatic geological section. The main outline of a new pattern is, however, already beginning to appear. We can distinguish in the Old Stone Age three cultural elements of primary importance. These are manifested in the so-called hand-axe industries, flake industries and blade industries, and we know that the first two, at any rate, run side by side as far back as we can see, and we are beginning to realize that the origins of the third may have to be sought much farther back than we had suspected. Only a moment of reflection is needed to see that we have here the old divisions of Lower, Middle and Upper Palæolithic, but with a new axis.

---

* From the presidential address to Section H (Anthropology) of the British Association, delivered at Blackpool on September 10.

These general considerations are necessary to clear the ground for the subject with which I am going to deal—those cultures the appearance of which in Europe towards the close of the Pleistocene marks the extinction of Neanderthal man and the arrival of *Homo sapiens*. In the main these are essentially blade cultures, though in certain areas industries of Mousterian tradition lingered on into Upper Palæolithic times. Now it is clear that these blade cultures must have passed through the early stages of their development somewhere outside Europe, during Middle or even Lower Palæolithic times, but we have at present only the faintest clues as to how and where that development took place.

The general conclusions which can be drawn from the material at our disposal may be summarized as follows. A point which stands out at once, and very clearly, is the diversity of the strains which have so far been grouped together under the name Aurignacian. So long as we were dealing only with Western Europe this did not matter very much, as everyone knew what was meant by the Lower, Middle and Upper Aurignacian, but when we come to regions in which the sequence is not the same, the use of these terms, with their chronological implications, is definitely misleading. Peyrony proposes to retain the label Aurignacian for the culture so far known as Middle Aurignacian, and to group all the industries characterized by the blunted-back blade under the heading Perigordian. This undoubtedly corresponds with a first, very important distinction, which has been recognized for some time, but it does not go far enough. Perigordian, like the former Aurignacian, is made to cover too much. In spite of fundamental resemblances which certainly suggest relationship, it is doubtful if the passage from the Chatelperron to the Gravette level is the simple evolutionary process supposed by Peyrony. The blade cultures, after all, have an immensely wide distribution, and it is unlikely that the key to their development is to be found in southern France.

If we take more distant regions into account, it becomes clear that the French sequence is the result of successive immigrations, superimposed, perhaps, on a certain amount of local variation and development in place. Since, however, this sequence is so familiar, and has for so long been accepted as a standard, I propose to make it my point of departure, and to examine its various stages in the light of the evidence now available, trying to trace each one back to its original centre. Afterwards it will be possible to shift our point of observation, and taking a wider view of the distribution map thus plotted, to see what general pattern emerges.

The first blade industry to reach Western Europe is that of the Chatelperron stage, Peyrony's Perigordian I, which is the former lower Aurignacian. The distinctive implement of this industry is, of course, the curved blunted-back blade, or Chatelperron point. The Chatelperron level—which, for convenience, I shall provisionally call Chatelperronian—has not so far been found in Central and Eastern Europe, but a similar though not identical industry occurs at the base of the Upper Palæolithic sequence in Palestine. This, however, is less primitive in appearance than that of France, and seems already to be in process of evolution towards something resembling the La Gravette stage. The Lower Capsian, which is characterized by curved points, was formerly regarded as the parent of the Chatelperron industry, but Vaufrey demolished this theory by demonstrating that it is later in time. On the other hand, the Lower Kenya Aurignacian appears to be more or less of Chatelperron type, and may be in part contemporary with this stage in France. We thus have at the beginning of the Upper Palæolithic three areas which may in a wide sense be called Chatelperronian, two of which, Palestine and East Africa, may have been in touch with each other through Arabia and across the Bab-el-Mandeb, while the third remains apparently isolated. The problem of how the Chatelperronian entered Western Europe without leaving any traces on the way is one that awaits solution.

Although the Chatelperronian only appears as a distinct industry at the beginning of the Upper Palæolithic, we can trace its essential features much farther back than this. The Levalloiso-Mousterian of Palestine, which covers a very long period, has yielded throughout a small proportion of well-made curved points, burins and end-scrapers, and in the Tabun cave on Mount Carmel, typical Chatelperron points, end-scrapers, and blades with abrupt retouch were relatively abundant all through a well-determined zone within the Final Acheulean. In Kenya also Leakey has found backed blades associated with the Upper Acheulean, and he suggests that the so-called Lower Aurignacian—the Chatelperronian—may have developed from the contact of the Acheulean and Levalloisian cultures, the makers of the Acheulean hand-axes borrowing from the Levalloisian the idea of making use of long narrow blades. This is not impossible, of course, but it should be noted that in the Upper Acheulean of Palestine, as in Western Europe, the flake industry which is actually associated with the hand-axes is in the Clactonian tradition, and the Chatelperronian tools look markedly out of place and intrusive, while in the Kharga Oasis, where a Levalloisian flake industry actually forms part of the late Acheulean, no Chatelperronian forms have been found.

I should like to put forward the alternative suggestion that the Chatelperronian already had an independent existence at this time, having developed in some centre still unknown, and that it is an intrusive element in the Acheulean. In trying to trace this centre, we must take into account the fact, which seems to me significant, that the two regions in which the presence of backed blades in the late Acheulean is clearly established are precisely those in which a distinct Chatelperronian industry appears at the beginning of the Upper Palæolithic. If—as I am inclined to do—we reject the theory that the Chatelperronian developed within the Acheulean, we cannot accept either Palestine or East Africa as its original home, but must place this somewhere within reach of both. An Asiatic centre seems inevitable, but it is impossible at present to be more precise.

After the early stages of the Upper Palæolithic, the Chatelperronian proper apparently ceases to exist. In Palestine, however, the Chatelperron point reappears unexpectedly in the final stage, which must be roughly contemporary with the Magdalenian, and it is present in the Lower Capsian at approximately the same moment. Now, Vaufrey's theory of the late arrival of the Capsian still leaves us in the dark as to its origin. In its general lines it is unlike either the Sabylian or the blade industries of Palestine. We have seen, however, that the Upper Kenya Aurignacian is a nearly typical Capsian, which seems to have developed in place from the so-called Lower Kenya Aurignacian. I would suggest that East Africa may possibly be the centre of origin of the Capsian, which would thus enter Little Africa already fully developed by way of the Sahara. The Capsian would thus derive many of its features direct from the Chatelperronian, though outside influences may also have played their part, especially in the development of the microlithic element. It is, for example, unlikely that so specialized a type as the micro-burin should have developed independently in the Sabylian and the Capsian.

As for the peculiar industry which closes the Upper Palæolithic sequence in Palestine, it is quite definitely Aurignacian rather than Capsian, in spite of the presence of Chatelperron points, and it may conceivably be a local development, arising on the fringes of our hypothetical Chatelperronian centre and the Aurignacian province of the Near East.

Turning back to the Western European sequence, we now reach the Aurignacian proper, the former Middle Aurignacian. Peyrony claims that this does not represent a real break in the sequence, but that the Perigordian continued to develop in certain sites side by side with the neighbouring Aurignacian. The stratigraphical evidence for this is, however, insufficient. Even if there is a certain overlap, as is probable, all the known facts are in favour of a general separation of the Chatelperron and La Gravette levels by the layers containing the Aurignacian.

This industry can be traced right across Europe, through Lower Austria, Hungary, Rumania, the Crimea, Transcaucasia and Anatolia into Palestine, where it is very abundant and covers a much longer period than in the West. This suggests that the East Mediterranean coast is not very far from the Aurignacian centre of dispersion, and I would suggest tentatively that this should be sought somewhere in the Iranian plateau.

It is an open question and a very difficult one, how far the Aurignacian and Chatelperronian have ultimately a common origin. Certain forms, such as the burin and end-scraper, are found in practically all blade industries, but the Aurignacian, with its use of types derived from cores and consequent development of a fluting technique, has distinctive features which point at least to independent evolution from an early date.

The next stages in the French sequence are those of La Gravette and Font-Robert, formerly grouped together as Upper Aurignacian, which Peyrony has labelled Perigordian IV and V. This industry has clear affinities with the Capsian, and in view of the possibility that the Lower Capsian may be roughly contemporary with it, the question of African influence must be re-examined at this point. For various reasons, however, I think it must be ruled out. Already in the Lower Capsian two very distinctive forms, the micro-burin and the microlithic lunate, are present, and if this industry were the parent of the Gravette-Font-Robert stage of Europe it would seem inevitable that these should occur there also. In fact, however, they enter Western Europe only with the Tardenoisian culture at a much later date. Again, if the Lower Capsian passed into France it must have been through the Iberian Peninsula, and we have seen that in that region Capsian influences appear only at the close of the Upper Palæolithic sequence. Finally, the Gravette-Font-Robert industry has a very wide distribution in central and eastern Europe, and its remarkable development in this region points rather to a Eurasiatic origin. If further evidence were needed, one could cite the complete absence in Little Africa of the very distinctive female statuettes which are constantly associated with this culture in Europe. It does not follow that there is no link between the Capsian and the Gravette-Font-Robert industry; I would suggest that both are derived from the Chatelperronian, but that their common features are due in part to convergent development, certain forms, such as the Gravette point, being evolved almost necessarily from their Chatelperronian prototypes.

I have suggested that an Eastern origin is indicated for the Gravette-Font-Robert industry, and we must now examine this rather more closely. In France the distinction between the Gravette level with its typical blunted-back blades, and the overlying Font-Robert level with tanged and shouldered points is quite clear, but the two are nevertheless very closely related. In Central and Eastern Europe the shouldered point stage predominates and is associated with a distinctive decorative art and apparently a great development of the cult of which female statuettes are the expression. I would suggest for these two very closely related levels the names of Lower Gravettian and Upper Gravettian respectively, the label Grimaldian being reserved for the special development and prolongation of the Upper Gravettian in the Italian Peninsula.

The theory of an eastern centre of dispersion for the Gravettian is based, of course, on this exceptional development in Central and Eastern Europe. I am influenced also by the fact that the female statuettes, the close connexion of which with the Upper Gravettian is incontestable, are very abundant in Russia, but occur only sporadically in Western Europe, where they have an unmistakably alien appearance in comparison with the indigenous naturalistic animal art which had already begun to develop in the Aurignacian.

Assuming an Eastern origin, we cannot regard Central Europe as the centre of dispersion, because we have clear evidence that the Gravettian is there preceded by the Aurignacian proper. In South Russia it is indeed the oldest blade industry so far found, but the geological evidence does not suggest that it is necessarily very early, though it may quite well be contemporary with the Aurignacian of the West. I do not think, however, that the centre of dispersion can lie very much farther to the east, because the lithic industry of Malta, which must be approximately contemporary, is not Gravettian at all, though the presence of statuettes and certain decorative motifs suggests either that Siberia was reached by influences from South Russia or that the particular cult of which female statuettes were the expression came to the Gravettian from the Far East.

We must now consider by what route an industry ancestral to the Gravettian could have passed into North-east Europe from our hypothetical Chatelperronian centre. We have seen that in Palestine the true Gravettian is absent, and that in southern Kurdistan it probably represents a relatively late migration from Russia. In Palestine, however, the Chatelperronian level which lies at the base of the Upper Palæolithic sequence already shows signs of evolution towards the Gravettian type, and it is possible that an industry of this character had already penetrated into the neighbourhood of the South Russian plain before the westward moving Aurignacian invasion had reached the Mediterranean coast.

I need not dwell on the Solutrean episode, which forms the next stage in the French sequence, as this is already well known and understood. The only addition to our knowledge in recent years has been the demonstration that the Solutrean penetrated farther to the east than was originally supposed from its Hungarian centre.

With the Magdalenian we reach a stage when migration on a wide scale gives way to local variations of the cultures already in possession. Apart from the Magdalenian itself, which is undoubtedly the most interesting and the most vital of these variations, we have the Grimaldian in Italy, in South Russia a degenerate industry of Gravettian tradition, in Palestine a kind of hybrid Aurignacian which may extend into the Crimea, in Egypt the Sabylian, in England the Creswellian, while the retreat of the ice sheet in northern Europe made way for the Hamburg culture which is apparently derived from the Upper Gravettian. To round off completely the story of the Palæolithic blade cultures it would be necessary to pursue a number of these branches into the Mesolithic, but the close of the Pleistocene, for general purposes, marks the end of an epoch in human history, and although no catastrophic change is visible, with the dawn of the Mesolithic a new order is already on its way.

If we now take a last general view of this theoretical picture, we see the Chatelperronian, the earliest identifiable phylum of the blade cultures, already emerging in Lower Palæolithic times, in some as yet unidentified Asiatic centre. Ultimately it sends out two branches, one into East Africa, to give rise to the Capsian, the other into North-east Europe, to develop into the Gravettian. Meanwhile another stock, the

Aurignacian, pushes westward, and separates these two great provinces. From the Aurignacian and Gravettian centres migrations pour into Central and Eastern Europe along the southern edge of the ice-sheet, and cultures which in their homelands tend to remain distinct and exclusive succeed and influence each other, until at the extreme limit of their journey we get the characteristic French sequence, which for so long was used as a standard for the rest of the world. Meanwhile, along the fringes of the original provinces interpenetration necessarily takes place, and we find the Upper Gravettian filtering along the valleys of the Zagros Arc into southern Kurdistan, while the Aurignacian penetrates northward into the Crimea. Finally, at the close of the Pleistocene, migration on a large scale comes to an end, and numerous local variations spring up all over the Palæolithic world.

Outside all this, meanwhile, lies the still mysterious Far Eastern province, with its mixed flake and blade culture. In its early stages this may conceivably have played a part in the evolution of the Aurignacian proper, and in this connexion it is perhaps significant that Gordon Childe reports the presence of a slit-base bone point at Malta.

The picture which I have outlined is admittedly largely speculative. I am prepared to be accused of domination by a *mirage orientale*, but to that I would reply that some of my colleagues seem to me at the moment to be unduly influenced by a *mirage africain*. Only further discovery will make it possible to decide between us.

Obituary

Dr. George Forbes, F.R.S.

DR. GEORGE FORBES, who died at Worthing on October 22 at eighty-seven years of age, was a well-known electrical engineer in the early days of electric lighting and electrical transmission of power. He was a man of great versatility, and in addition to electrical engineering work he did much useful physical research and was also greatly interested in astronomy. He was an intimate friend of the late Sir David Gill, formerly H.M. Astronomer at the Cape of Good Hope.

After taking his degree at Cambridge, Forbes was appointed professor of natural philosophy at Anderson's College, Glasgow, and occupied the chair from 1872 until 1880. One of his chief pieces of physical work was an extensive research on the velocity of light, carried out in conjunction with Dr. T. Young, between 1876 and 1880 and described in the *Phil. Trans. Roy. Soc.* of 1882. They used a modified form of Fizeau's method and an arc lamp as a source of light, working over a Scotch loch for a distance of about 3–4 miles. The result they obtained was 301,382 kilometres per second, which is rather in excess of the best results of Michelson and others. The chief novelty of their work was that they found a supposed greater velocity for blue light than red by about 1·8 per cent. Astronomical observations give, however, a denial to such a conclusion and it has not been held to be valid. Forbes also took part in astronomical expeditions, and when only twenty-five years of age he conducted a British party to Hawaii to observe a transit of Venus with the object of determining the solar parallax and distance. He wrote an excellent small book in Benn's Sixpenny Library Series on "The Earth, the Sun, and the Moon".

When electric lighting work began in England in the early 'eighties of last century, after the invention of the carbon filament electric lamp by Edison and Swan, Forbes came to London and was adviser or manager of one of the then formed electric manufacturing companies. He made improvements in an arc lamp and invented an electric meter for alternating electric currents. One of his most permanent improvements was the application of hard graphitic carbon as brushes for electric motors. Before that time it was usual to employ brushes of brass or copper gauze or wire; but these caused unnecessary wear of the commutator. Forbes suggested brushes made of graphitic carbon in the same fashion as arc lamp carbons, and this was a great improvement and is used almost entirely at the present day.

When the great scheme of utilizing the power of Niagara Falls for production of electric current was under consideration, Forbes was one of those (and also the writer of this notice as well) consulted by the projectors as to the system of generation to be employed. In 1891 there was an electrical exhibition at Frankfort-on-Main, and one of the most interesting features was the transmission of power electrically over a distance of 110 miles from Lauffen to Frankfort by means of three-phase alternating electric currents. This transmission comprised the use of 300 h.p. generated at 55 volts and a frequency of 40 cycles. The voltage was raised by transformers to 8,500 volts and reduced again at the receiving end. The success of this performance gave a great impulse to the vaster scheme of utilizing Niagara, and the Cataract Company was formed to carry it out. After taking numerous opinions, it was decided to employ two-phase alternating currents, and generators driven by turbines were constructed of 5,000 h.p. to generate at 5,000 volts for transmission at 11,000 volts to Buffalo and other cities. Forbes went to Niagara to superintend the electrical work. At present, nearly a million horse-power is taken from the Falls.

Forbes travelled extensively, and in 1877 acted as special correspondent of *The Times* during the Russo-Turkish War. He was the recipient of many distinctions for his scientific work. He was elected a fellow of the Royal Society of London in 1887 and received the honorary degree of LL.D. from the University of St. Andrews. He was a Chevalier of the Legion of Honour of France and an honorary member of the Franklin Institute of America.

Forbes invented a range-finder for military work used in the South African War, and a gun-sight for the Navy. He was granted a Civil List Pension in 1931 for his services. Of late years he had not been seen much in scientific society, except for occasional visits to the Athenæum, but in the later years of the nineteenth century he was a well-known member of various British scientific societies and often seen in social and scientific gatherings. He was at one time a vice-president of the Institution of Electrical Engineers. An obituary of him appeared in the *Daily Telegraph* of October 26 last from which by permission some of the above statements are taken and acknowledgement is here made for the courtesy.

J. A. F.

Sir George Hampson, Bt.

SIR GEORGE HAMPSON, who died on October 15, at Thurnham Court, near Maidstone, at the age of seventy-six years, came of an ancient Oxfordshire family, the baronetcy having been created in 1642; he succeeded to the title on the death of his uncle in 1896. He was born on January 14, 1860, the eldest son of the Rev. W. S. Hampson, rector of Stubton, Lincolnshire. He was educated at Charterhouse and at Exeter College, Oxford, where he graduated.

Already in 1883 Hampson was collecting Lepidoptera, as a side-line to planting tea, in the Nilgiri Hills in southern India, and his serious interest in entomology appears to have been born during the five years which he spent in these surroundings. The latter half of the nineteenth century was a kind of golden age in the history of entomological discovery in India, when Marshall and de Nicéville, Moore, Swinhoe, Bingham, Butler and others were constantly extending and gradually reducing to some sort of order our knowledge of the Indian Lepidoptera. But whereas these workers were principally concerned with the butterflies, Hampson, no doubt largely inspired by their activities, after producing a "Catalogue of the Butterflies of the Nilgiris" (which remained in MS.), turned his attention to the moths, in the study of which he was later to achieve a world-wide and unique reputation.

By 1889, Hampson was busily engaged as a voluntary worker in the Insect Room of the British Museum, both upon the general arrangement of the Heterocera and, more particularly, the Indian moths. In 1891 and 1893 the Trustees of the Museum published his first considerable works, namely, his accounts of the Heterocera of the Nilgiris and of Ceylon, which formed Parts 7 and 8 of the "Illustrations of Typical Heterocera in the British Museum". The four volumes, and supplements, of the "Moths of India" appeared between 1892 and 1896, forming part of the Fauna of India series issued by the Government of India; these set the seal upon his reputation and remain still the only comprehensive work on the subject.

Meanwhile Hampson had been offered an appointment as assistant under Dr. Günther in the Department of Zoology in the British Museum. He accepted this post, and took up his duties in January 1895. This placed him in charge of the whole of the collection of moths, and immediately he concentrated his attention almost exclusively upon the production of his truly monumental "Catalogue of the Lepidoptera Phalænæ in the British Museum". Between 1898 and 1923 fifteen volumes were published. This was, in fact, an attempt at a fully documented and illustrated descriptive catalogue of the moths of the world, and manifestly too great a task for any one man to perform. Yet it is amazing how much Hampson achieved, and how much more he had achieved than was ever published, for on his retirement in 1920 he left a great quantity of manuscript, of which the bare bones were issued in 1926 as a single volume entitled "New Genera and Species of Noctuidæ in the British Museum". The catalogue included the Syntomidæ, Arctiidæ, and the major part of the Noctuidæ, that is to say, perhaps one third of the moths which are usually called Macrolepidoptera. Yet during the progress of this work, Hampson found time to publish many valuable and extensive papers dealing with the large and important family of Pyralidæ, notable among which is his account of the Phycitinæ and Galleriinæ (in continuation of Ragonot's work) which formed vol. 8 of the Romanoff "Memoirs".

Times have changed greatly in entomological circles since Hampson took up his task. His working equipment consisted of a hand lens, benzene (for temporarily clearing the wings) and a pair of dividers. It is scarcely a matter of surprise that more recent investigations have brought to light many facts which escaped him. He was always more inclined, too, to concede a far greater range of variation in species than was customary at the time his early volumes appeared, possibly as a reaction to the obviously unjustified hair-splitting of such workers as Butler, Moore and Swinhoe, and in consequence, especially in the "Moths of India", some of his "species" have been shown to be compact of many. There can be few systematists, however, against whom such a charge cannot be levelled.

The present writer remembers well, as a very young man, his first introduction to Hampson. He had some foreign moths to name, and on asking for help, was firmly but courteously told that "he would find them over there—" a wave of Hampson's arm indicating the entire collection of Heterocera in the Museum. This was very characteristic; but it had some advantages. It enabled the speaker to proceed uninterrupted with his work, and it forced the inquirer to learn something about the moths in such a way that he would remember it. Hampson's methodical industry was amazing, and his "Catalogue" is not only a worthy testimony to it, but also a mine of information that will not be exhausted for many years.

N. D. R.

Sir George Buchanan, C.B.

THE death, on October 11, of Sir George Buchanan, a devoted public servant in public health, will be regretted by a wide circle of friends. George Seaton Buchanan was born on February 19, 1869. He was the eldest son of the late Sir George Buchanan, F.R.S., who was principal medical officer to the Local Government Board from 1880 until 1892. The younger Buchanan graduated at the University of London with the degrees M.B. (gold medallist), 1891; M.D., 1892; M.D. (State medicine), 1893; and B.Sc.; and became later a fellow of the Royal College of Physicians. In 1895, at the age of twenty-six years, he was appointed to a post of medical inspector in his father's old Department, then under the leadership of Sir Richard Thorne-Thorne. After serving for nearly forty years in this Department and the Ministry of Health, which was created from it, he retired at the age limit of sixty-five years in 1934, but continued to hold the office of president of the Permanent Committee of the Office International d'Hygiène publique in Paris (which carries with it the vice-presidency of the Health Committee of the League of Nations in Geneva) to which he had been elected in 1932. His soul was devoted almost exclusively to the public service, and he thus, after leaving the British Government service, was able to continue public health work of international importance.

When first appointed to the Local Government Board and for many subsequent years, Sir George was occupied in making epidemiological inquiries into outbreaks of infectious disease in England and Wales. He became president of the Epidemiological Section of the Royal Society of Medicine in 1918 and 1919. His first published report in 1897 on an inquiry into enteric fever in some districts of East Anglia provided an early proof of the disease being due to polluted oysters. A few years later, his epidemiological inquiry into the manner in which smallpox spread during an epidemic in Essex supported the view (first brought to notice by Power in 1881 and again in 1884) that smallpox can be spread, from hospitals receiving acute cases of this disease, by distal atmospheric convection, apart from personal contact.

From 1901 until 1903, Sir George Buchanan acted as secretary to Lord Kelvin's Royal Commission on food contaminations, which led in 1905 to the organization by the Local Government Board of a new section with Buchanan at its head with the title of 'Chief Inspector of Foods'. In 1912 he became first assistant medical officer under Sir Arthur Newsholme, then chief medical officer of the Board. Two years later, by his appointment as official delegate for Great Britain on the Permanent Committee of the Office International d'Hygiène publique in Paris, he entered the field of international public health affairs, which thereafter formed his chief public health work. During the Great War, he served on special commissions which visited Gallipoli, Egypt, Salonica and Mesopotamia, and the honour C.B. (Military) was conferred upon him for these services. When peace came, his services on the Army Sanitary Committee and the Inter-Allied Sanitary Commission in Paris were retained, and he continued to take an active part in international arrangements for preventing the spread of typhus, dysentery and other diseases which affected troops and refugees returning from the war areas.

His valuable services in solving various international health problems cannot be enumerated here, but special mention must be made of the large share Sir George took in designing and drafting the International Sanitary Maritime Convention which was agreed upon and signed at the International Sanitary Conference held in Paris in 1926. Later he took similar action in drawing up international rules for the prevention of transmission of yellow fever and other infectious diseases by aircraft. These rules were embodied in the "International Sanitary Convention for Aerial Navigation" which is now in force. The activities of the international health organizations in Paris and Geneva are given in full in the Milroy Lectures on "International Co-operation in Public Health, its Achievements and Prospects" delivered by Buchanan before the Royal College of Physicians of London on February 27 and March 1, 1934.

The honour of knighthood was conferred on Buchanan in 1922. He was appointed master of the Society of Apothecaries of London for 1934–35, and in the same year was awarded the Mary Kingsley Medal by the Liverpool School of Tropical Medicine and the Jenner Medal by the Royal Society of Medicine in London for his work in the control and prevention of epidemic diseases.

DR. JAN BAŠTA, a distinguished Czechoslovak engineer and member of the Masaryk Academy of Work, died in Prague on October 13 aged seventy-six years. He was the first student to graduate from the Prague Technological University in 1902. Later he had a distinguished career as a railway engineer, but never lost his keen interest in pure science. His last publication, dealing with the relationship of force with matter, was referred to in NATURE of July 11 last p. (83).

WE regret to announce the following deaths:

Prof. H. R. Briton-Jones, professor of mycology in the Imperial College of Tropical Agriculture, on November 3.

Dr. Kurt W. Franke, chemist at the South Dakota Agricultural Experiment Station, known for his work on enzyme action and nutrition, on September 15, aged forty-six years.

Mr. C. E. Haselfoot, fellow (formerly dean) of Hertford College, Oxford, lecturer in mathematics in Wadham College, from 1888 until 1913, on October 28, aged seventy-two years.

Prof. Henry Landes, professor of geology and dean of the College of Science, University of Washington, an authority on the mineralogy of Washington, on August 23, aged sixty-eight years.

Mr. A. E. Hodge, founder and editor of the *Aquarist and Pond-Keeper*, aged fifty-eight years.

News and Views

Medal Awards of the Royal Society

HIS MAJESTY THE KING has approved of the following awards this year by the president and council of the Royal Society in respect of the two Royal Medals: to Prof. R. H. Fowler, for his work on statistical mechanics and allied departments of modern mathematical physics; and to Prof. E. S. Goodrich, for his work on the morphology of the excretory organs of the invertebrata and for his work on the comparative anatomy and embryology of the vertebrata. The following awards of medals have also been made by the president and council: Copley Medal to Sir Arthur Evans, in recognition of his pioneer work in Crete, particularly his contributions to the history and civilization of its Minoan Age; Rumford Medal to Prof. E. G. Coker, for his researches on the use of polarized light for investigating directly the stresses in transparent models of engineering structures; Davy Medal to Prof. W. A. Bone, for his pioneer work on contact catalysis and his researches on the mechanism of combustion of hydrocarbons and on the nature of flames and on gaseous explosions; Darwin Medal to Dr. E. J. Allen, in recognition of his long-continued work for the advancement of marine biology, not only by his own researches but also by the great influence he has exerted on very numerous investigations at Plymouth; Hughes Medal to Dr. W. Schottky, for his discovery of the Schrot effect in thermionic emission and his invention of the screen-grid tetrode and a superheterodyne method of receiving wireless signals.

New Officers of the Royal Society

THE following is a list of those recommended by the president and council for election to the council of the Royal Society at the anniversary meeting on November 30: *President*, Sir William Bragg; *Treasurer*, Sir Henry Lyons; *Secretaries*, Sir Frank Smith and Prof. A. V. Hill; *Foreign Secretary*, Sir Albert Seward; *Other members of Council*, Prof. A. J. Allmand, Dr. G. T. Bennett, Prof. J. Chadwick, Prof. A. S. Eve, Prof. W. G. Fearnsides, Prof. L. N. G. Filon, Dr. J. Gray, Sir Daniel Hall, Prof. C. R. Harington, Prof. D. Keilin, Prof. J. Graham Kerr, Dr. R. H. Pickard, Mr. H. R. Ricardo, Prof. W. Stiles, Prof. W. W. C. Topley, Mr. W. Trotter.

Frederick Wollaston Hutton, F.R.S. (1836–1905)

ON November 16, the centenary occurs of the birth of the distinguished geologist Frederick Wollaston Hutton, who together with Ferdinand von Hochstetter (1829–84), Sir John F. J. von Haast (1824–87) and Sir James Hector (1834–1907), laid the foundations of our knowledge of the geology of New Zealand. Hutton was born at Gate Burton, Lincolnshire, being the second son of the Rev. H. F. Hutton. Educated at Southwell Grammar School and the Naval Academy, Gosport, he spent three years as a midshipman in the India Mercantile Marine and then entered the Army. He served in the Crimean War and the Indian Mutiny, and afterwards at Sandhurst gained a liking for geology from Prof. Thomas Rupert Jones (1819–1911). Leaving the Army in 1866, he went to New Zealand. In 1871 he became an assistant on the New Zealand Geological Survey, and two years later was made Government geologist of Otago. In 1877 he was appointed professor of natural science at the University of Otago and in 1880 settled in Christchurch as a professor in the University of New Zealand. Besides a large number of scientific papers, he published "Darwinism and Lamarckism" (in 1899), "The Lesson of Evolution" (in 1902) and "Animals of New Zealand" (in 1904). After an absence of nearly forty years, he revisited England, and was on his way back to New Zealand in the S.S. *Rimutaka* when he died at the Cape on October 27, 1905. After his death, a subscription was raised for the endowment of a bronze medal in his honour, and for the furtherance of research.

The Background to Harvey

IN his Harveian Oration delivered before the Royal College of Physicians on October 19 and published in the *British Medical Journal* of October 24, Sir Walter Langdon-Brown, emeritus professor of physic in the University of Cambridge, described the background to Harvey as represented by contemporary thought, of which Francis Bacon, Robert Burton, the author of "The Anatomy of Melancholy", John Donne, the Dean of St. Paul's, Sir Thomas Browne, Thomas Hobbes, the author of "Leviathan", and the Cambridge Platonists were the chief exponents. Like Sir William Hale-White in his Harveian Oration of 1927, Sir Walter maintained that the "Novum Organum", in which the new spirit of England found its clearest expression, had a deep influence on the mind of Harvey who, as his medical adviser, came in close contact with Bacon. A striking contrast was offered by John Donne, who represented a transition from the sixteenth to the seventeenth century, being in certain aspects the most medieval and in others the most modern writer of his time. In conclusion, Sir Walter showed how the turmoil of thought in Harvey's time is being repeated to-day. In both instances a phase of great and rapid expansion both in thought and wealth was followed by disillusionment on the intellectual side and greater stringency on the financial; old standards were destroyed before new ones could take their place and a new form of art and literature appeared.

The Chemical Exploration of the Stratosphere

For his Friday evening discourse at the Royal Institution on November 6, Prof. F. A. Paneth took as his subject "The Chemical Exploration of the Stratosphere". Prof. Paneth pointed out that while the temperature and the electrical state of the stratosphere have been the object of many investigations, its chemical composition has seldom been studied. If winds are absent, or at least rare in the stratosphere, we should expect a partial separation of the atmospheric gases under the gravitational field of the earth. In order to decide this question of the stillness of the stratosphere, samples of air have to be collected. For this purpose, the sending up of automatic devices in unmanned balloons is the most efficient method. In collaboration with the Meteorological Office of the Air Ministry, Prof. Paneth and Dr. E. Glückauf, working at the Imperial College of Science and Technology, have developed methods for the automatic collection and subsequent analysis of air samples from the stratosphere. From the first results, published a year ago, it was concluded that up to 18 km. no definite change in the chemical composition of the stratosphere occurred, but that at a height of 21 km. the relative amount of the light gas helium has already distinctly increased. During the last few months, this has been confirmed by further successful flights reaching more than 23 km.

Similar investigations have lately been started by Prof. E. Regener, in Stuttgart, using larger balloons; in one of his samples, from a height of more than 28 km., he found an oxygen deficit, in good agreement with the helium surplus detected in the London flights. The only two air samples obtained by manned stratosphere balloons confirm these findings: Prokofiev's sample collected over Russia in 1933 at a height of 19 km. showed no variation in its composition; but the air brought back by Capt. Stevens and Capt. Anderson from 22 km. over the United States already revealed a slight oxygen deficit. All this supports the conclusion that from about 20 km. onwards the stratosphere is quiet enough to permit a partial separation of its constituents by gravity. Neither the London nor the Stuttgart samples show a gradual change in the composition of the atmosphere in proportion to altitude. This is of special interest as it proves that in spite of their relative quietude, the air masses even of higher layers of the stratosphere are liable to disturbances, probably corresponding to weather conditions.

The Royal Society of Arts

For his inaugural address delivered on November 4 to the Royal Society of Arts, Sir Henry McMahon, chairman of the Society, took as his subject "One Hundred and Eighty Years of Pioneer Work by the Royal Society of Arts". The Society was founded in 1754 "for the Encouragement of Arts, Manufactures and Commerce" at a time when there were no departments of Government, societies or institutions to deal with such matters as Colonies, agriculture, forestry, fine arts, health, trade or industry. In the early days, the field of work was divided into six sections, each being left to the charge of a separate committee. Money prizes, or premiums as they were called, and in some cases gold and silver medals, were then offered for specific objects, and in this way a very great stimulus was provided for improvements in all directions. The agricultural industry in particular derived much benefit from such a policy. At the time of the foundation of the Society, agricultural methods were largely based on medieval practice. In the second half of the eighteenth century, the Society took an important share in developing a more scientific outlook. The prizes offered by the Committee on agriculture covered a very wide range, including the improvement in the quality and yield of established crops, such as wheat, barley, oats and rye, the introduction of new grasses and roots for cattle feeding, better methods of cultivation, the invention of new types of agricultural machinery and the improvement of existing models, the use of manures, soil analysis, the management of sheep and cattle, and indeed almost every aspect of what is now understood by the term 'scientific agriculture'.

The offer of rewards did not always produce results. For example, a handsome reward was offered and renewed for no less than forty-six years (1774–1820) for an effective corn-reaping machine, without success. One of the most useful pieces of work for which the Society can claim credit was the introduction of the swede and mangel-wurzel into Great Britain. Remarkable results were also achieved by the Society in connexion with afforestation carried out in the period 1758–1835, anticipating in fact the work of the present Forestry Commission, which was not founded until 1919. Much attention has also been paid by the Society to the polite arts, the importance of encouraging the art of drawing in many employments, trades and manufactures being recognized from the start. The introduction of industrial exhibitions was a feature of the pioneer work in this direction, and the success of the Exhibition of British Art in Industry in 1935 was an indication of the desire on the part of both designers and manufacturers of the present time to increase this spirit of co-operation.

Prevention of War

There can be no doubt of the general and passionate determination of the great majority of the thinking youth of the world to prevent another world war. This desire is strongly expressed by the New History Society, of 132 East 65th Street, New York, and illustrated by its offer of prizes amounting in the whole to five thousand dollars for the best papers submitted on the subject of "How Can the People of the World achieve Universal Disarmament?" The essays are to be of not more than two thousand words in length, and the prizes are variously graded from one thousand dollars downwards, so that there seems abundant opportunity for any helpful contribution sent in from any part of the world to receive some recognition. We recommend all sympathizers to obtain the necessary further particulars from the address above. The last date for the posting of the essays is May 1, 1937, so that ample time is allowed for all inquiries and for the writing of so short a composition. It will not be the length, however, but the pregnancy of what is said that will arouse attention, and one hopes most sincerely that something may be said which will bring light and hope to this most perplexing and dangerous question. Everyone knows, and most people admit, for example, that Great Britain in this matter of rearmament is acting most unwillingly and feels herself compelled to her present action by what is being done by others. If this is to go on, the vicious circle is complete. How to break it? That is the question to which the essayists will have to address themselves.

IT is not for us here to sketch an essay for the competition, but it does seem possible that after our darkest moment light may appear. The appalling business which now absorbs our attention in Spain may prove the turning point for an upward movement of peace. It is clearly seen that this conflict is a reflection, in a distorted form, of the greatest underlying conflict which is threatening the peace all over the world, that between what is called 'fascism' or an authoritarian and comprehensive nationality, and 'communism' or the organized power of the manual workers. Men see now the hideous excesses and dangers of extinction which threaten civilization, if such a conflict is pushed to extremes. They must see also that, as in England, there is no essential reason why the conflict should not be avoided by rational compromise and goodwill. There is an honest and widespread movement on foot to avoid extreme courses in the case of Spain. Clearly something must be done there, to save that country from extinction. This may be the lesson which the world so badly needs. It is at least plainly written in the events of the last three months. The friends of science will also reflect that the crisis has occurred in the one land in Western Europe where science had taken least root, the one place where there was no renascence of science in the seventeenth century. That was the proper scene for the play of the forces of unreason. No other Western land has been torn by such an internecine strife; no other was so unfortunately free from the pacifying influences of scientific education.

Spawning of the Common Toad

IT is only during recent years that biologists have realized that they are far from a complete understanding of the influence of external factors on the spawning of even the commoner amphibians. The common toad (*Bufo bufo bufo*) is an 'explosive breeder', that is to say, all the sexually mature individuals in a district migrate from their diverse hibernation quarters to their breeding sites within a few days of one another, and within even large areas there is singularly little deviation from the normal of the year. There have been occasional records of isolated pairs found spawning long after the normal time, but some observations made by Mr. G. Shrubsole, who writes from the Victoria Court Hotel, Eastbourne, made during the last two years, seem to indicate the existence in Sussex of an area which is exceptional. A series of small ponds on Beachy Head were visited at intervals for conchological work, and on July 30 and August 1, 1935, unhatched toad spawn was found in at least three of them. One pond was kept under observation and unmetamorphosed tadpoles were still found at the beginning of December. In 1936 tadpoles were first found in the same, and one other pond, at the beginning of May, but never throughout the year were they ever observed in any of the others. The development of the tadpoles was apparently very slow, for even in September the majority still had mere rudiments of hind-limbs. But whether these very late tadpoles were of the same brood as those found early in May is uncertain (the normal larval period is only 12–14 weeks), for although no fresh spawn was found, adult toads were discovered in the water in July. Their presence at a time so long after tadpoles had been observed is unusual, for the whole of the breeding operations are normally concluded within a week or so, and the adults then leave the water for the rest of the year. Their presence certainly suggests the possibility that there may have been a July spawning in 1936, as there was in 1935, and, if this proves to be a regular occurrence, a detailed investigation of the physical conditions of the district should be of importance.

Native Labour from Nyasaland

THE announcement by the Colonial Office that the Governments of Southern Rhodesia, Northern Rhodesia and Nyasaland have entered into a provisional agreement regulating the employment of emigrant labour from the last-named has come shortly after Mr. Ormsby-Gore's recent insistence on the importance of the labour problem in its effect on the well-being of the native community (see NATURE, Oct. 31, p. 735). It is an assurance that the conditions to which the report of the Committee on emigrant labour from Nyasaland has directed attention will not be allowed to continue without a serious endeavour to eliminate those factors which have been shown to be the cause of hardship and suffering, as well as a danger to the future prosperity of the Protectorate. The agreement is to remain in force for four years as from August 21 last, and thereafter is terminable at twelve months notice. Under its terms, identification certificates are to be issued to all male natives seeking employment, and those leaving their own territories for that purpose will bear evidence to that effect, as well as a notification of physical fitness. In future, so far as native and industrial conditions permit, only such certificated labour will be admitted by the employing Governments. Not only will the flow of labour be controlled, if necessary, but also—a matter of much greater importance—labourers are to be returned to their own territory after an economic period of employment, which is not to exceed two years. This provision, even if it does not entirely remove the evil of a permanent loss in population, will at least lessen the numbers of those who do not return to their homes after a period of extra-territorial employment. A further important provision sets up a standing committee of representatives of the three Governments to secure co-ordination and to consider problems in connexion with the supply of labour as they arise.

Population Investigation Committee

IT is announced in *The Times* of November 5 that a committee has been formed to investigate the fall in the birth-rate in Great Britain and its probable consequences. The committee, which has been appointed by the council of the Eugenics Society, is presided over by Prof. A. M. Carr-Saunders, and has among its members, Lord Horder, Mrs. Hubback, Dr. Julian Huxley, Prof. L. Hogben, Dr. R. R. Kuczynski, Lady (Rhys) Williams, Prof. J. Young, and other authorities on various aspects of the subject. Dr. C. P. Blacker, the general secretary of the Eugenics Society, is honorary secretary of the Committee, and Mr. D. V. Glass is research secretary. Mr. Glass has recently published a useful book on this subject, entitled "The Struggle for Population". The committee has already held two meetings, and its investigations are gradually taking shape. The main object is, in the first place, to ascertain the facts of the case and the causes of the decline in the number of births per family; and for this purpose it invites the co-operation of institutions and individuals engaged upon relevant lines of research. Inquiries may be addressed to the Secretary, Population Investigation Committee, 69 Eccleston Square, London, S.W.1.

New Discharge Bulb Lamps

THE new discharge bulb lamps are already in use on the Continent, and judging from the fact that they were shown at a meeting of the Illuminating Engineering Society on October 13, they will probably be soon on sale in Great Britain. In appearance, they are like the ordinary 'pearl' lamp but they have no filament. They contain a small quartz mercury vapour discharge lamp "about the size of half a cigarette" and they are corrected for colour. Internally the bulb is coated with a fluorescent powder, in the same way as the lower area of the inside of the cathode ray tube, where the picture is shown in television reception. According to the *Electrical Contractor* of November, the lamps are available in two sizes, 80 watts and 125 watts. The light output of these lamps is about 40 lumens per watt. This compares with the 12 lumens per watt of the ordinary coiled-coil incandescent lamp. The life is stated to be about 1,500 hours. The 'colour correction' of these lamps is effected by the fluorescent powder used. The human complexion when illuminated by the lamps shown at the meeting was very little altered, the change being scarcely noticeable. Owing to the fact that the internal film transforms the invisible ultra-violet light emitted by the mercury vapour lamp into light of visible wave-length, the loss of light by the absorption of the bulb is compensated for by this fluorescence. No details are yet available as to the price of the lamp, but we seem to be on the eve of a new development in house lighting.

Recent Acquisitions at the Science Museum

THE Oxford heliometer of 1848 has been placed on exhibition in the Astronomy Collection (Gallery LXIV). This instrument was made for the Radcliffe Observatory, Oxford, by Messrs. A. and G. Repsold of Hamburg on the advice of the famous German astronomer F. W. Bessel, who had in 1838 with a similar instrument obtained the first satisfactory measure of the parallax of a fixed star. The distance of the star, 61 Cygni, was found to be some 400,000 times the sun's distance of 93,000,000 miles. The Oxford heliometer was for many years one of the most powerful and accurate instruments of its kind in the world. It is notable among other things for the first application of electrical illumination to an astronomical instrument. It was dismounted and taken to pieces in 1906, and so remained until its removal in 1935 to the Science Museum, where it has been renovated and set up as it was originally, a striking testimony to the nineteenth century instrument maker's art. In the Chemistry Collection (Gallery LXVI), an original tube of the metal rhodium prepared by its discoverer, Dr. William Hyde Wollaston, about 1825 has been placed on exhibition. Rhodium has recently become of interest as a non-tarnishing substitute for silver in electroplating.

Zoological Survey of India

THE report of the Zoological Survey of India, recently issued, covers the years 1932–35, coinciding with a period of retrenchment in civil expenditure and consequent restriction of activities. It records the retirement of Lieut.-Colonel R. B. Seymour Sewell in 1933, and his subsequent extensive biological investigations as leader of the Murray Oceanographical Expedition to the Indian Ocean, and is written by his successor, Dr. Baini Prashad. The investigations of the Survey include detailed work upon the *Trochus* shell fisheries of the Andaman Islands; identification of animals of economic importance from the medical or sanitary point of view, carried out for various institutions and public bodies; identification of human and animal remains excavated at various chalcolithic sites in Sind; and anthropological work connected with the census. Unfortunately, the abolition of the post of zoological collector and the necessity of restricting expenditure has greatly reduced the field-collecting and observations which used to be so desirable and characteristic an activity of the Survey.

Bibliography of Seismology

THE last two quarterly numbers of the "Bibliography of Seismology" prepared by Mr. E. A. Hodgson and printed in the Publications of the Dominion Observatory, Ottawa (12, 159, 181;

1936), complete the record for the year 1935 and begin that for the present year. The general impression that one receives in reading over the titles is that references are gathered from more varied sources and that the bibliography is increasing much in usefulness. The last number for 1935 contains an index classified according to the subjects of the various memoirs catalogued during the year. A useful feature of both numbers is the list of references to notes or short articles that have appeared in various journals, such as NATURE, *Science*, etc. The first number for 1936 shows that Great Britain is represented among the collaborators by Dr. E. Tillotson, 23 Roseville Road, Leeds, 8, who will be glad to receive notices of papers on any seismological subjects published in Great Britain.

Veterinary Education

THE following Committee has been appointed by the Secretary of State for Scotland and the Minister of Agriculture and Fisheries "to review the facilities available for veterinary education in Great Britain in relation to the probable future demand for qualified veterinary surgeons and to report thereon, and in particular to make recommendations as to the provision which should be made from public funds in the five years 1937–42 in aid of the maintenance expenses of institutions providing veterinary education": The Right Hon. Sir Thomas Molony (chairman), Sir James Currie, Dr. Thomas Loveday, Sir John Robertson, Mr. John Smith. Mr. V. E. Wilkins, of the Ministry of Agriculture and Fisheries, and Mr. W. N. McWilliam, of the Department of Agriculture for Scotland, have been appointed joint secretaries of the Committee.

Poultry Mortality Committee: New Chairman

ARISING out of a recommendation of the Eggs and Poultry Reorganisation Commission for England and Wales, a Committee was set up some months ago by the Secretary of State for Scotland and the Minister of Agriculture and Fisheries "to consider the present methods of supply and distribution of hatching eggs, day old chicks, and breeding stock, both generally and with particular reference to the reduction of poultry mortality; and to make recommendations for the improvement of those methods". The Committee's proceedings were however suspended by the illness, recently followed by death, of its chairman, the late Mr. F. N. Blundell. Sir Duncan Watson has now been appointed chairman of the Committee. The secretary of the Committee is Mr. V. E. Wilkins, of the Ministry of Agriculture and Fisheries.

Rat Control Film

THE Ministry of Agriculture and Fisheries has recently produced a new cinematograph film dealing with the loss and damage caused by rats and mice and the measures which may be taken for their destruction. The film, which is entitled "Your Enemy—The Rat", is available in two versions—a short sound film for display in public cinemas, and a longer silent version designed for display at exhibitions, conferences, etc. Copies of the film will be loaned free of charge. Applications for bookings should be addressed to the Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, London, S.W.1.

Royal Prowess in Ancient Egypt

No little interest and some amusement has been aroused by the inscribed stela of Amenhotep II discovered at Giza, on which the monarch transcends the customary royal assumption of credit for achievement by an intimate personal touch in his description of his prowess as an oarsman and athlete. The stela, which was found in the course of Prof. Selim Hassan's excavations in the neighbourhood of the Sphinx at Giza (*The Times*, Nov. 7), records that Amenhotep, when visiting Giza as a young man to pay homage to his ancestors Khufu and Khephren, had rowed a boat for three miles against the stream with an oar twenty ells long without fatigue, while his boatmen were tired after rowing for half a mile. As a horseman and archer he was no less remarkable. He had trained his horses to draw his chariot at a gallop without sweating, and shooting from his chariot he had pierced with an arrow copper targets which were as thick as his hand. The stela upon which is the inscription also bears above a representation of the king making offerings to a figure which is said to be identifiable as the god Ra. It was set up in the second year of Amenhotep's reign (1447 B.C.). The expedition of which Prof. Selim Hassan is in charge is engaged in clearing the whole area adjacent to the Sphinx, and with this purpose in view additional land, at present encumbered with refreshment booths, has been purchased to obviate interference with the work of excavation.

Institute of Physics: London and Home Counties Branch

THE inaugural meeting of the London and Home Counties Branch of the Institute of Physics was held on November 4 under the chairmanship of Mr. E. R. Davies, director of the Kodak Research Laboratory. This, the third branch of the Institute to be formed in Great Britain, has been created in response to the desire expressed by some three hundred members resident in London and the surrounding districts. The formation of these branches serves to demonstrate the growing number of physicists in industry who wish to have opportunities for social intercourse and discussion of problems of mutual interest. At the meeting numerous suggestions were made for activities that the branch might usefully undertake; these included visits to works and industrial research laboratories, discussions on professional matters, and short groups of lectures on recent advances in physics. It was emphasized that it is not intended to hold meetings for the reading of original papers, as this is the function of the Institute's participating societies, namely the British Institute of Radiology, the Faraday Society, the Physical Society, and the Royal Meteorological Society. Full particulars of the new branch may be obtained from Dr. H. Lowery, honorary secretary of the branch, North-Western Polytechnic, Prince of Wales Road, N.W.5.

Science and War

THE Association of Scientific Workers is organizing a public meeting and discussion on "Defence and the Responsibilities of the Scientist", to be held in the mathematics lecture theatre, Huxley Building, Royal College of Science, Exhibition Road, South Kensington, on Thursday, November 19, at 8 p.m. The chair will be taken by Prof. J. B. S. Haldane, and the speakers will include Prof. S. Chapman and Air Commodore L. E. O. Charlton. It is the purpose of the meeting to provide a forum for the full discussion of problems arising out of the increasing application of science to war. Measures that might be adopted by scientific workers as an organized body to further the cause of peace will also be considered.

Announcements

IT is announced in *The Times* of November 6 that Dr. Edward Bohane, director of the Royal Dublin Society, is retiring from this post on a pension of £1,900 a year and a gratuity of 7,500.

MR. M. A. C. HINTON, deputy keeper of zoology in the British Museum (Natural History), has been elected zoological secretary of the Linnean Society for the remainder of the present session, in succession to Dr. Stanley Kemp, who has resigned.

PROF. L. A. ORBELI, of Leningrad, has been appointed a member of the Permanent International Committee of the Physiological Congresses in succession to Prof. I. P. Pavlov, who died last February. The Committee therefore is now constituted as follows: Profs. F. Bottazzi (Italy), W. B. Cannon (U.S.A.), O. Frank (Germany), A. V. Hill (Britain), secretary, B. A. Houssay (Argentine), Y. Kuno (Japan), L. Lapicque (France), G. Liljestrand (Sweden), and L. A. Orbeli (U.S.S.R.).

THE following have been elected as officers of the Cambridge Philosophical Society for the year 1936–37: *President*, Dr. F. W. Aston; *Secretaries*, Dr. J. D. Cockcroft, Mr. A. H. Wilson, Dr. O. M. B. Bulman; *New Members of Council*, Prof. E. V. Appleton, Mr. G. E. Briggs, Dr. A. N. Drury, Mr. A. E. Ingham, Dr. D. Stockdale.

THE centenary of the foundation of the Army Medical Library of the United States, generally known as the Library of the Surgeon-General's Office, will be celebrated at Washington, D.C., on November 16, when Sir Humphry Rolleston will deliver an oration on its history with special reference to Billings, Fletcher and Garrison.

PROF. A. BUTENANDT, director of the Institute of Organic Chemistry of the Technical University at Leipzig, has been appointed director of the Kaiser Wilhelm Institute of Biochemistry at Berlin-Dahlem, and has been awarded the Rinecker Gold Medal by the University of Würzburg.

THE recent decline in the birth-rate in Japan is shown by the following figures: 1932, 100,688 births; 1933, 927,209 births; and 1934, 809,224 births.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

An agricultural organizer for Gloucestershire—The Clerk of the County Council, Shire Hall, Gloucester (November 16).

Two district officers in the Forestry Commission—The Secretary, Forestry Commission, 9 Savile Row, London, W.1 (November 17).

A research bursar in physiology in the National Institute for Research in Dairying, Shinfield, near Reading—The Secretary (November 20).

A divisional engineer to the London County Council—The Clerk of the Council, County Hall, Westminster Bridge, London, S.E.1 (November 20).

A principal scientific officer, a senior scientific officer, a scientific officer (quote C.E. 6634/36) and a junior scientific officer (quote C.E. 6873/36), with qualifications in chemistry, physics, mathematics or engineering in the Admiralty Scientific Pool—The Secretary of the Admiralty (C.E. Branch), Whitehall, London, S.W.1 (November 21).

An assistant lecturer in engineering in the Brighton Technical College—The Education Officer, 54 Old Steine, Brighton (November 23).

A principal of the Luton Technical Institution—The Director of Education, Shire Hall, Bedford (November 24).

Two assistants (Grade II) (physics or chemistry) and one assistant (Grade III) (physics or chemistry) in the Explosives Directorate; and two scientific officers (mathematics), one scientific officer (engineering or mechanical sciences), one scientific officer (physics or electrical engineering), one assistant (Grade I) (physics or electrical engineering), one assistant (Grade II) (mathematics) and two assistants (Grade III) (physics or electrical engineering) in the Ballistic Directorate of the Research Department, Royal Arsenal, Woolwich, S.E.18—The Chief Superintendent (November 24).

A demonstrator in physics in the London (Royal Free Hospital) School of Medicine for Women—The Warden, 8 Hunter Street, Brunswick Square, W.C.1 (November 25).

A Stokes student for research in mathematical or experimental physics in Pembroke College, Cambridge—The Master (December 1).

A Tweedie exploration fellow in archæology and anthropology in the University of Edinburgh—The Secretary (May 12).

Mechanical and electrical engineers in the Royal Army Ordnance Corps—The Under-Secretary of State (A.C. 9), The War Office, London, S.W.1.

An economic geologist in the Mineral Resources Department (Intelligence Section) of the Imperial Institute, South Kensington, London, S.W.7—The Establishment Officer.

Veterinary officers in the Colonial veterinary service (vacancies in Malaya, East Africa and West Africa)—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1.

Assistant civil engineers in the drawing office of the Civil Engineer-in-Chief's Department, Admiralty, London, S.W.1.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 846.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Rates of Cleavage of Sea Urchin Eggs in Different Latitudes

THE oxygen consumption of various kinds of poikilothermal marine animals in English waters is higher, at the temperatures at which they live, than that of northern and arctic species of the same genera at their lower sea temperatures, although the arctic animals seem to move about just as fast in their cold habitat as do the English forms in our own waters[1]. The same relation holds for ciliary movement on the gills of scallops: the cilia beat more rapidly in the English species. On the other hand, the respiratory movements of English Crustacea are no more rapid at, say, 15° than those of arctic species at 5°. The same rule applies also to the rates of heart-beat of most of the species studied. I have now measured the rate of cleavage of eggs, and find that this behaves like the respiratory movements and hearts, not like oxygen consumption and cilia.

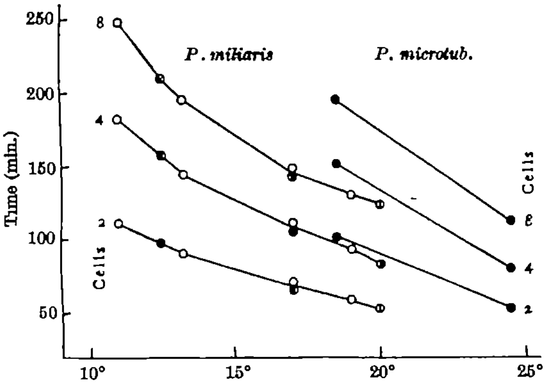

FIG. 1. Time for cleavage of sea urchin eggs. ○, Plymouth; ⊖, Millport; ⦶, Roscoff; ●, Tamaris.

I have compared the rates of cleavage of the eggs of two species of sea urchins, *Psammechinus miliaris* from Roscoff in Brittany[2], Plymouth, and Millport in Scotland, and *P. microtuberculatus* at Tamaris in the south of France. The results are shown in Fig. 1. The points giving the times after fertilization, for the first three cleavages at different temperatures in *P. miliaris* from the various localities fall, on smooth curves, but the eggs of the Mediterranean species at a given temperature, say 20°, cleave much more slowly than those of the northern species. The rate for the southern species at 20° is no faster than that for the northern species at 12°–13°.

From data in the literature, it is evident that the same phenomenon occurs within a single species of sea urchins, namely *Paracentrotus lividus*. At Roscoff the 2-, 4- and 8-cell stages are reached in 66, 100 and 147 minutes at 20°[2]. At Rovigno, in the Adriatic, the respective times are 105, 135 and 182 minutes at the same temperature[3]. Indeed the cleavage rates of *P. lividus* at Naples differ at different times of the year. At 13°, 71 and 91 minutes elapse between one cell division and the next in winter and in summer respectively, while at 26°, 31 minutes are taken in winter and 25 minutes in summer[4].

The results described above will be published in full in the *Proceedings of the Zoological Society*.

Physical Nature of Certain of the Vibrating Elements of the Internal Ear

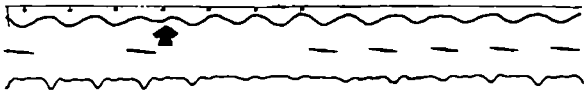
THE sensation resulting in the human subject from a change of phase of π (180°) occurring in the course of a continuous musical tone has been the subject of a number of earlier publications[1]. Under certain conditions, the sensation has been found to resemble the beat produced by two pure tones slightly out of unison, and has been described as a "phase-change beat"[2]. As stated by Hartridge[1], it is demanded by the Helmholtz resonance theory that the physiological event which corresponds to such a phase-change beat must be a transient arrest of the resonant elements of the internal ear brought about by the opposition of the impressed forces following the change of phase to the after-swings enforced by resonance.

An experiment is described below in which direct evidence is adduced that an event of this kind does in fact take place.

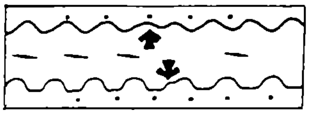
For the purpose of acoustic stimulation, the phase-reversing photo-electric siren to which reference is made elsewhere[3] has been employed. By means of this device, tone frequencies of 256 ∼ and 1,024 ∼ and of 40–80 phons intensity were generated and led by means of thick-walled rubber tubes to the ear of an animal preparation (decerebrate cat).

Employing suitably disposed electrodes and an amplifying system of conventional resistance-capacity type to feed a cathode ray oscillograph, the electrical response of the cochlea (Wever and Bray phenomenon), and also the auditory action-potentials of the mid-brain, were recorded photographically upon fast-moving cine-bromide. In addition, arrangements were made for the simultaneous recording of the sound stimulus by means of a piezo-microphone feeding a separate amplifier and oscillograph.

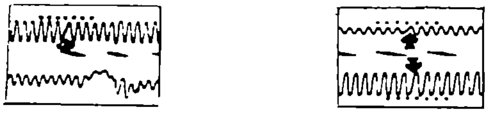
The records depicted in Fig. 1 show that in the case of the auditory tract potentials, the response is of the resonant type, in that it exhibits a well-marked 'silent period' in correspondence to the change of phase occurring in the stimulating tone. This finding is considered to provide clear evidence of the occurrence under the conditions described of a transient arrest of the vibrating elements responsible for the initiation of the auditory action potentials. As stated by Hartridge, this phenomenon is explicable only upon the hypothesis of Helmholtz that these elements are resonant structures. The widely held view that the elements in question are the fibres of the basilar membrane is accepted.



256 ~ Microphone and auditory tract response.



256 ~ Microphone and cochlear response.



1024 ~ Microphone and auditory tract response.

1024 ~ Microphone and cochlear response.

FIG. 1. Oscillograph records of auditory tract and cochlear responses to 180° phase changes. In all the records, the upper tracing represents the microphone response; arrows indicate the position of the phase-changes. Time marker, 1/200 sec.

In the case of the cochlear response, the records displayed in Fig. 1 show that no such silent period occurs, and that further, the change of phase in the stimulating tone is reproduced with considerable fidelity. This finding provides evidence which enforces the view that the cochlear response differs fundamentally in its mode of origin from that of the auditory action-potentials recorded, as in the present experiment, from the tracts of the mid-brain. The fidelity of reproduction of the impressed phase change must be taken as indicating the light, but heavily damped, character of the moving parts responsible for the generation of the cochlear response, and is in clear accordance with the membrane hypothesis of its origin put forward in a previous publication[4]. This hypothesis regards the potential changes in question as originating in movements occurring in a polarized membrane. Reissner's was considered to be such a membrane, and a possible mechanism of polarization was suggested, based upon the known differences of origin of the endolymph and perilymph.

The more widely accepted hypothesis of Davis and his collaborators[5], that the cochlear phenomenon originates in the manner of a piezo-electric effect from the hair-cells of Corti's organ, must in the light of the present findings be regarded as untenable, in view, first, of the direct attachment of these cells to the basilar fibres, and secondly, of the failure of the phenomenon to exhibit any silent period in response to a phase-reversal such as is now shown to be imposed by the resonant character of these fibres upon other anatomically associated elements, namely, the terminal fibrils of the cochlear nerve.

The Theory of Phase Transitions

THE only phase transitions which up to the present time have been thoroughly investigated are transitions between the liquid and gaseous states. As regards transitions between liquids and crystals or between different crystalline modifications, their treatment has not always been quite satisfactory. For example, one sometimes hears not only of transition points (with jumps of energy) and Curie points (with jumps of specific heat), but also of transition points of the *n*th order, as if there were reason to assume that such generalized transitions can really exist. Some transitions have been attributed to the rotation of molecules, although I cannot see how rotation by itself can lead to discrete transitions. The idea seems to exist that there can be an absolutely continuous transition between the liquid and crystalline state (analogous to the transition liquid-gas), which would require the existence of a miraculous state which is neither isotropic nor anisotropic.

A mathematical treatment of the problem can be developed by introducing a density function $\rho(x,y,z)$, which determines the probability density for an atom or an electron to be found at a given point x,y,z. The symmetry of this function determines the symmetry group of the crystal. For liquids, $\rho(x,y,z)$ is a constant. For the investigation of continuous or nearly continuous transitions, we can write $\rho(x,y,z) = \rho_0(x,y,z) + \delta\rho(x,y,z)$, expand the thermodynamic potential in powers of $\delta\rho$ and investigate the minimum properties of this expression.

Such an investigation in the most general form, the details of which will appear elsewhere, leads to the following results. There exist only two kinds of transition points (more exactly lines in the p-T diagram), namely, phase transition points and Curie points. Curie points are only possible when the symmetries of both modifications are different and the symmetry group of one modification is a certain sub-group of the symmetry group of the other. Thus, for example, the symmetry of the ammonium chloride molecule changes at the Curie point from O_h to T_d, which is a sub-group of O_h. In alloys the change of symmetry consists generally in a doubling of the lattice constant.

If the relation between the more symmetrical group and the sub-group does not satisfy certain conditions, no Curie point line in the p-T plane is possible. But there is still a possibility of a continuous transition (without a jump in the energy) at a single point in the *p-T* plane. The *p-T* diagram near this point has in the simplest case the form shown in Fig. 1. Here I denotes the region of the more symmetrical phase. II*a* and II*b* are two different phases with the same symmetry, which is that of a subgroup of I. At the point *O* all the three phases become identical.

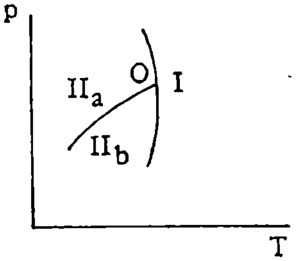

FIG. 1.

It can be shown that the transition crystal-liquid belongs to this class. No Curie point line can therefore exist for melting, and the only possible type of continuous transition crystal-liquid is that shown in Fig. 1, where in this case I refers to the liquid and II to the crystalline state.

Emission of Beta-Rays from Substances bombarded with Neutrons

IT is well known that a Geiger-Müller counter placed near a target containing heavy hydrogen gives a large number of responses when the target is bombarded with deuterons of considerable energy. Oliphant[1], and later Alexopoulos[2], stated that these radiations are unable to induce simultaneous discharges in two thin-walled Geiger-Müller counters placed side by side, and concluded that no gamma-ray of energy higher than 1×10^6 ev. accompanies the D–D reaction. Results contrary to these authors have been obtained repeatedly by us[3] using Geiger-Muller counters the walls of which were made of aluminium 0·1 mm. in thickness. But as the energy of the electrons was nearly equal to that of secondary electrons of gamma-rays excited by fast neutrons in several elements, we consider that they might have been due to the gamma-rays excited in several parts of the apparatus by the action of neutrons emitted not only from the target but also possibly from different parts of the accelerating tube bombarded by stray deuteron beams.

We have now performed the experiments with a different arrangement in which the secondary effects are minimized, and confirmed that the radiation in question cannot be ascribed to any secondary origins. From the ratio of the number of coincident discharges to the number of responses of the single counter, it is estimated that the greater part of the discharges taking place in the single counter is due to the electrons, which are also responsible for the simultaneous discharges. The absorption curve of the beta-rays indicates that most of the electrons had energy lower than 1·0 mv., while a small portion of them had somewhat higher energy extending up to 1·5 mv. (In the single counter experiments, the counter was in most cases covered with a sheet of lead 0·5 mm. in thickness to protect it from the electrons, which might be emitted from the walls of the boron box in which the counter was placed. In the case of double counter experiments, semi-cylindrical lead covers 1·0 mm. thick were attached to the outer sides of the counters.)

Now, we can consider two possibilities: (1) the gamma-rays are emitted in the D–D reaction; or (2) the beta-rays are emitted under the action of fast neutrons from the substances of which the counter, including lead covers, is constructed. To decide between these alternatives, lead and aluminium absorbers 2 cm. in thickness were inserted between the target and the counter. The effect of the gamma-rays excited in the absorbers was allowed for. The decrease in the rate of discharge of the counter was conclusively in favour of the second alternative.

We further investigated the change in the number of responses when the lead cover 0·5 mm. in thickness was replaced by the sheets of carbon, aluminium, iron, nickel, copper, zinc, silver, cadmium and platinum of about 0·5 gm./cm.^{2} thickness, which was sufficient to stop the beta-rays of energy lower than 1·3 mv. A similar effect was observed in each case, and the effect seems to increase rather smoothly with the atomic number, while the energy of the electrons remains constant within the experimental error.

In explaining this phenomenon, the effect of ordinary induced radioactivity is excluded, for we could observe no activity remaining after the bombardment. It was easily proved impossible to explain the observed large effect by the gamma-rays excited in the walls of the counter and its cover, which were comparatively small. The only possible explanation in terms of the reaction hitherto known is the excitation of the nucleus by the fast neutrons, and subsequent emission of the extra-nuclear electrons through internal conversion. If this be true, the coefficient of the internal conversion must be very large, that is, nearly equal to unity for all the elements investigated, including light elements such as carbon and aluminium. Further, the smooth dependence of the effect on the atomic number seems to indicate also the inappropriateness of the assumption.

We must then assume some new types of interaction of the neutron with atoms, such as the direct interaction of neutrons with the bound electron, or the disintegration of a neutron into an electron and a proton in the nuclear field. The cross-section of the process was estimated to be of the order of 10^{-25} cm.^{2} for the light elements and 10^{-24} cm.^{2} for the heavy elements. These values are very much higher than those expected from existing theories. The observed energy of the electrons is what might be expected from the disintegration of neutrons. If this assumption be correct, we should have to find trident tracks, consisting of an electron, a proton and a recoil atom, in a Wilson chamber traversed by neutrons in amount well above the error of observation.

A detailed account of the experiments will be published in the *Proc. Phys.-Math. Soc. Japan* soon.

An X-Ray Study of Sulphuric and Orthophosphoric Acids

THE study of X-ray diffraction patterns of liquids is one of the least indirect means of obtaining information concerning their structure, but the amount of information is restricted by the limitations of the theory. The straightforward application of the original Debye theory[1] leads to an expression for the intensity of scattering

$$I = I_0 \frac{e^4}{m^2c^4} \cdot \frac{P}{R^2} F^2 \left[1 + \int_0^\infty 4\pi r^2 [g(r) - \rho] \frac{\sin sr}{sr} \, dr \right] . \quad . \; (1)$$

where I_0 is the intensity of the incident beam, P is the polarization factor, R the distance from specimen to point of observation; $4\pi r^2 g(r)dr$ represents the number of atoms or molecules lying within radii r and $r + dr$; ρ is the mean density in atoms or molecules per c.c., e, m and c have their usual significance, and $s = 4\pi \sin \theta/\lambda$, where θ is half the scattering angle.

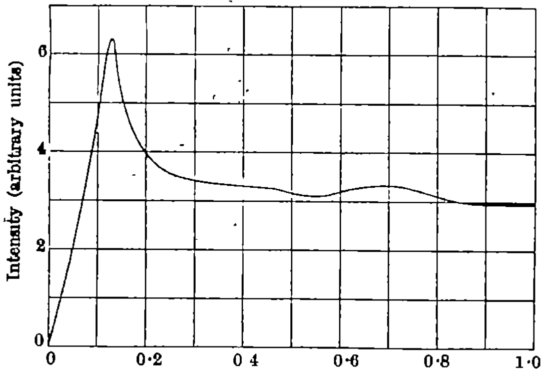

FIG. 1. Scattering of molybdenum $K\alpha$ radiation by orthophosphoric acid.

In the simple case of an atomic liquid, such as sodium, F^2 is identical with f^2, the square of the atomic scattering power. By the use of Fourier inversion, it can be shown that:

$$4\pi r^2 g(r) = 4\pi r^2 \rho + \frac{2r}{\pi} \int_0^\infty s\varphi(s) \sin rs \, ds \quad . \quad . \quad . \quad (2)$$

where

$$\varphi(s) = \frac{(I/kP - f^2)}{f^2} \text{ and } k = \frac{I_0 e^4}{m^2c^4} \cdot \frac{1}{R^2}.$$

$\varphi(s)$ can be derived from a knowledge of f^2 and the experimental scattering curves, and it is therefore possible to obtain a Fourier analysis of the distribution of matter in the liquid[2,3].

For a molecular liquid

$$F^2 = \Sigma_p \, \Sigma_q \, f_p \, f_q \frac{\sin sr_{pq}}{sr_{rq}},$$

and a knowledge of the internal structure of the single molecule is necessary before (2) can be applied. $g(r)$ then gives the distance apart of *molecular* centres.

In the case of sulphuric and orthophosphoric acids, the rigid tetrahedral nature of the SO_4 and PO_4 groups is beyond question, and it was thought to be of interest to determine the arrangement of molecules in the liquids. (When f^2 becomes F^2, $g(r)$ refers to molecules and not to atoms.) Strictly speaking, orthophosphoric acid is a sticky solid, but a trace of water, about 1 per cent, is sufficient to turn it into a liquid.

The Fourier analysis is not yet complete, but it is clear that the scattering curves for the two liquids are almost identical, each having one main sharp diffraction band at an equivalent spacing of 3·85 A. There are, however, minor differences between the curves at larger values of sin θ/λ. Fig. 1 shows the scattering curve for orthophosphoric acid, taken with molybdenum radiation, and corrected for lack of polarization in the incident beam.

Further studies of other acids and molecules of roughly spherical shape should be of interest. The theory takes no account of molecular rotation; in spherical molecules this effect should be of minor importance, and the Fourier analysis can be relied on to give a fairly accurate picture of the average distance apart of molecules in the liquid.

Specific Heat of a Liquid at Different Temperatures

IT is possible to measure the specific heat of a liquid at a number of different temperatures by determining the power required to hold the temperature of a calorimeter and its contents stationary at different temperatures above that of the surroundings. The power is supplied electrically to a coil immersed in the liquid, and we have

$$-(Ms + W) \, d\theta/dt = E^2/RJ.$$

If a cooling curve is now taken, it can be shown that within the limits of experimental error,

$$-d\theta/dt = K\theta^n,$$

where n is nearly, but not exactly, equal to 5/4, K and n being determined by the use of a least-square or some equivalent method. We thus have

$$(Ms + W) K\theta^n = E^2/RJ,$$

giving the specific heat s in terms of the 20° calorie, if an experiment be performed with water at 20° C.

The method has proved to be surprisingly sensitive, and gives results which are reproducible with a very high degree of consistency. We have used the method to determine the specific heat of water over the range 15° – 45° C., and, by the very great kindness of Imperial Chemical Industries Ltd., we were able to conduct an experiment with heavy water of 99·2 per cent purity over the same range. The sample of heavy water lent to us was 375 gm. in mass, and, although this is relatively a large quantity of a rare liquid, it is small compared with the quantity demanded by a continuous-flow experiment. The accompanying table gives results in terms of the 20° calorie:

Temp.	Water	Heavy water
15° C.	1 0010	$1·009_0$
20° C.	1·0000	$1·007_0$
25° C.	0 9991	$1·005_4$
30° C.	0·9986	$1·004_3$
35° C	0·9984	$1·003_8$
40° C.	0·9984	$1·003_9$
45° C.	0 9986	$1·003_7$

It will be seen that the results for deuterium oxide are consistently higher than the values for water, and that a minimum value is shown at about 41° C.

These values, which were announced at the Blackpool meeting of the British Association, are preliminary in character, and may be subject to small corrections.

Effect of Large Centrifugal Forces on *Paramecium*

THE effect of subjecting *Paramecium* to large centrifugal forces has been investigated and has given some encouraging results.

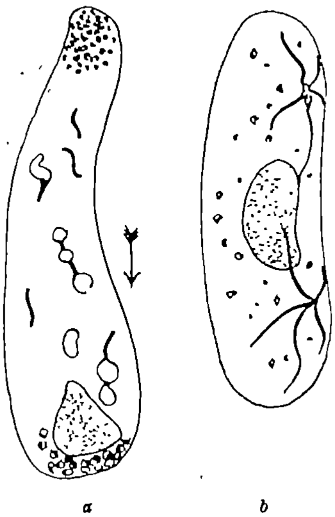

FIG. 1. (*a*) Centrifuged, (*b*) control *Paramecium*. The arrow indicates the direction of the force.

Fig. 1 illustrates the effects produced. The animal becomes elongated. The nucleus and crystals are moved to the centrifugal side, the excretory mechanism is fragmented, the canals being torn away from the pore and enlarging to form vacuoles. In addition, there is a collection of small granules visible after the Golgi methods, both osmic acid and silver. These granules are moved towards the centripetal pole, and it is thought that they may be Golgi bodies of a rudimentary type.

Diffraction of Light by Ultra-sonic Waves

WE have recently given a theory of the diffraction of light by ultra-sonic waves, which is quite general and leads to numerical results for the diffracted intensities[1]. In this paper, we considered normal incidence only ; we have now calculated some diffraction patterns at oblique incidence. We found these in good agreement with the experimental results of Parthasarathy[2].

Parthasarathy apparently explains the observed asymmetry of the diffraction pattern by the "characteristic reflection" of light on the ultra-sonic wave, although we know from the theory of diffraction of X-rays in crystals that this reflection is simply a consequence of the equations of propagation. In fact, even for X-rays, as Ewald has shown[3], Bragg's angle of reflection is not sharp, but spreads out over a region which covers a few seconds of arc, and our theory shows that for ultra-sonic and light waves this region is much larger and may cover as much as a few degrees.

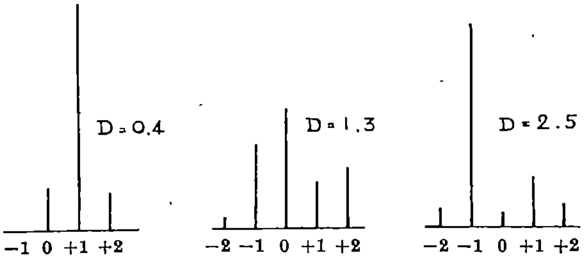

FIG. 1. Intensity of the diffracted light in the various orders for three different values of the thickness d of the ultra-sonic beam. The light is incident obliquely in the direction of the + 1 order, the 0 order being on the normal to the direction of the ultra-sonic wave. d is connected to the pure number D which appears in the figures through the relation $D = \frac{\pi \lambda}{\Lambda^2} d$, λ and Λ being the wave-lengths of the light and of the sound waves respectively.

The three diagrams reproduced (Fig. 1) show the calculated intensities in the different orders of diffraction for different thicknesses of the beam of ultra-sonic waves. The angle of incidence and the intensity of the ultra-sonic waves have been kept constant. One sees clearly that the repartition of intensity among the different orders is a function of the thickness of the ultra-sonic beam. The reason for this is that the intensity of a wave diffracted in Laue fashion is a quasi-periodic function of the thickness of the diffracting medium (corresponding to the *Pendellösung* of Ewald for X-rays).

Our diagrams exhibit the asymmetry which is the main feature of Parthasarathy's photographs. It is, of course, impossible to obtain more than qualitative agreement, without precise information about the intensity and breadth of the ultra-sonic beam.

The geometrical representation of Ewald allows an interpretation of the equivalent Brillouin theory, which clarifies greatly the apparent mathematical complexity of the latter. In fact, one can reason out very simply the exact solution of the problem of diffraction, and this seems much easier than trying to solve it approximately, as N. S. Nagendra Nath has done in a recent paper[4].

The complete report of our investigation will appear shortly in the *Helvetica Physica Acta*.

I wish to thank Prof. Weigle for his valuable advice in this work.

Sodium and Water Metabolism in Relation to Disturbances of Carbohydrate Metabolism after Adrenalectomy

We have found that in the absence of the adrenal cortex, flavin is not transformed to flavin phosphoric acid, but that adrenalectomized animals can be kept alive with large quantities of the latter substance (vitamin B_2)[1]. We have also shown that lack of adrenal cortex causes serious disturbances in intermediate metabolism of carbohydrates and fats, particularly in the absorption of these substances[2-5]. In the following experiments, we have tried to show how these facts are related to the well-known disturbances of water and sodium metabolism which may cause death in adrenalectomized animals.

The selective absorption of glucose is inhibited after adrenalectomy, and this is due to the absence of the cortex, since it can be restored by administering cortical hormone[1]. We have now demonstrated this by injecting a mixture of glucose and xylose (each in half blood-isotonic solution) into a ligatured loop of a rat's intestine. From such a solution, glucose disappears four times as quickly as xylose, in normal animals, and in adrenalectomized animals the ratio is almost 1 : 1, that is, both sugars are absorbed at the same rate.

Table 1. Absorption of a mixture of 3 c.c. of 5·4 per cent glucose and 3 c.c. of 4·5 per cent xylose from a 60 cm. loop of intestine in a rat during one hour.

	Injected (gm.)		Absorbed (gm.)		Ratio of Absorption
	Glucose	Xylose	Glucose	Xylose	
Normal rats	0·162	0·135	0·146	0·034	4·3 : 1
Adrenalectomized rats	0 162	0·135	0·049	0·028	1·7 : 1

If the selectively rapid absorption of glucose from an intestinal loop is inhibited by poisoning the animal with iodoacetic acid, then sodium salts diffuse into the interior of the intestine more rapidly than glucose leaves it; hypertony results, and a large quantity of water enters the intestine by osmosis[6]. Exactly the same happens when the selective absorption of glucose is inhibited by adrenalectomy. The intestine is found to be full of fluid one hour after glucose administration. The example given in Table 2 is typical of many such experiments.

Table 2. Absorption of 5·4 per cent glucose solution from a 30 cm. intestinal loop of a rat during one hour.

	Glucose (gm.)		Fluid movement (c.c.)	
	Injected	Absorbed	Injected	Found
Normal rat	0·162	0·147	3	0 6
Adrenalectomized rat	0·162	0·042	3	3·5

Thus in adrenalectomized rats, ingestion of glucose causes great losses (into the intestine) of sodium by diffusion and of water by osmosis. Therefore the adrenalectomized animals, in contrast to normal rats, develop intensive diarrhœa after glucose administration. This is also seen in normal animals after the administration of xylose, which is slowly absorbed, or after glucose with iodoacetic acid poisoning, when the glucose is also slowly absorbed.

Thus the inhibition of the selective absorption of glucose in adrenalectomized animals leads *secondarily* to losses of sodium salts and water. Similar disturbances are possible in the intermediate metabolism of carbohydrates and fats[2-5].

These secondary disturbances of loss of sodium and water may be the cause of death of adrenalectomized animals which can be prevented by giving sodium salts. In several cases, rats adrenalectomized 8–15 days before, died in 3–5 hours when 5 c.c. of 50 per cent glucose solution was fed by stomach tube. A second group of such rats survived when sodium chloride and carbonate were given simultaneously. This supports the above explanation.

Biosynthesis of Ascorbic Acid

Some time ago[1], we observed that incubation of some tissues of the rat with mannose in a mixture of Ringer-Locke solution and phosphate buffer at *p*H 7·4 resulted in an increase of the ascorbic acid value, as determined by the usual titrimetic technique with 2 : 6-dichlorophenol indophenol[2]. The experiments *in vitro* were supported by experiments *in vivo*, in which it was shown that the injection of mannose into the rat also caused an increase in the ascorbic acid content of some of its tissues[3]. Cell-free extracts were also obtained from germinating *Phaseolus mungo*, which were likewise capable of converting mannose into ascorbic acid[4].

Euler, Gartz and Malmberg[5] have, however, not been able to detect the above conversion with the tissues of the rat. Their experiments indicate that they worked in an atmosphere of nitrogen, and that they compared the ascorbic acid values of the fresh tissues with the values obtained after incubation with mannose. We repeated the following experiments in order to clear up the discrepancy. 0·5 gm. of the finely minced tissue was used in each case, suspended in a mixture of 3 c.c. Ringer-Locke solution and 2 c.c. phosphate buffer of *p*H 7·4, to which 1 c.c. of a freshly prepared aqueous solution, containing 20 mgm. mannose, was added. This was shaken up and incubated for 3 hours at 37° in a 25 c.c. conical flask closed with a rubber cork. The flask was not shaken any more. The control vessel contained 1 c.c. water instead of the mannose solution. Two other vessels contained the same two mixtures in an atmosphere of nitrogen. The results are shown in the accompanying table:

Ascorbic acid (mgm.) per 0·5 gm. liver tissue.

Expt.	In nitrogen		In air		
	With mannose	Without mannose	With mannose	Without mannose	Percentage of increase in air
1	0·29	0·29	0·27	0·20	35
2	—	—	0·21	0·19	10
3	0·32	0·32	0·25	0·21	18
4	0·32	0·32	0·21	0·18	16
5	0·22	0·22	0·18	0·18	23
6	—	—	0·097	0·080	21

These figures show that in an atmosphere of nitrogen the amount of ascorbic acid remains constant, whether mannose is added or not. But in a closed volume of air, if the experiments are carried out precisely under the conditions mentioned, there is an increase in the amount of ascorbic acid on incubation with mannose. The ascorbic acid value thus obtained after incubation with mannose in air is, however, invariably lower than the value obtained with the fresh tissue, and cannot naturally be compared with it. The figures obtained after incubation with and without mannose are alone comparable. It appears from these results that molecular oxygen is necessary for the conversion with which we are dealing.

Similar results have been obtained with the aqueous extracts of germinated *Phaseolus mungo*, which can also convert mannose into ascorbic acid at *p*H 5·8 in a closed volume of air but not in nitrogen. Numerous experiments have been carried out in this connexion, and they will be reported later.

Expansion Pressures of Metallic Hydrogen and Deuterium

FROM a recent calculation[1], it follows that the striking difference in properties between hydrogen and lithium is due to the great stability of the covalent H–H link. Metallic hydrogen (the analogue of metallic lithium) would be formed from hydrogen atoms with an evolution of about 10 kcal. per gm. atom, but is only stable with respect to diatomic hydrogen molecules at pressures not less than $2 \cdot 5 \times 10^6$ atmospheres.

Although these pressures have not been experimentally realized, it is possible to investigate the properties of metallic hydrogen (Graham's hydrogenium) in some of its alloys. There is evidence that in the 'hydrides' of transitional elements such as tantalum, palladium and nickel, as well as in solutions of hydrogen in other metals at high temperatures, the hydrogen is in the metallic state, that is, is dissolved as atoms, and is partly dissociated into protons and electrons[2].

One of the most readily investigated properties is the expansion pressure. Although on purely geometrical grounds the hydrogen atoms and protons could fit into the interstices of the metal lattice with which the hydrogen is alloyed, metallic hydrogen exerts a considerable expansion pressure. For palladium, with a compressibility of approximately $0 \cdot 4 \times 10^{-6}$ per atmosphere, an expansion pressure of $2 \cdot 5 \times 10^5$ atmospheres would lead to an expansion of 10 per cent in volume, whereas the observed value, when approximately 0·5 gm. atom H is added per gm. atom Pd, is 11 per cent.

In a recent communication[3], a method is described for investigating special problems in the structures of solids, by making use of the differences in zero point energy when deuterium is substituted for hydrogen. The changes are usually quite large enough for X-ray investigation, and provide an additional parameter which can be varied in studying the equilibrium of the lattice. In the case of the metallic linkage, for example, it is possible to obtain an estimate of the differences in expansion pressures of metallic hydrogen and deuterium, by measuring the expansion of the palladium lattice when alloyed with each of these isotopes.

As is discussed in a forthcoming publication, the expansion of the palladium lattice leads to an increased heat of solution of hydrogen, with the result that below about 300° C. two phases with atomic ratio H/Pd about 0·02 and 0·5 are formed, with the same lattice structure and the same dissociation pressure of hydrogen. By investigating these two phases in equilibrium, when either hydrogen or deuterium is dissolved in palladium, it is found that the average expansion in the lattice parameter on forming the β-phase is 0·1430 ± 0·0004 A. for hydrogen, 0·1325 ± 0·0004 A. for deuterium. The concentration of deuterium in the β-phase is slightly greater than in the case of hydrogen, and the expansion pressures of these two isotopic metals differ by about 7 per cent.

The lattice energy of transitional metals appears to be particularly sensitive to volume changes, and information about the energy changes involved may be obtained by alloying with each of the two isotopes.

Viscosity of Binary Mixtures

SEVERAL attempts have been made to represent the viscosity, η, of a mixture, as a function of the concentrations, c_1 and c_2, and the viscosities, η_1 and η_2, of the components. So far as we are aware, all investigators (with the exception of Dolezalek) have used the general form:

$$f(\eta)=c_1.f(\eta_1)+c_2.f(\eta_2)$$

with various expressions for f, such as $f=\log \eta$ (Arrhenius), $f=1/\eta$ (Bingham), $f=\eta^{1/3}$ (Kendall and Monroe). The latter demonstrated very clearly that, with any of these functions, deviations up to 20 per cent and more appear, when used for mixtures of two liquids with very different physical constants. As a matter of fact, there is no reason to suppose that any expression of this general form can give satisfaction.

Let N_1 and N_2 be the mole fractions of the two components; let us denote by z_1 the interaction of one particular molecule of kind 1 in the layer A with a molecule of the same kind in layer B, and by z_{12} the interaction with a molecule of kind 2. The relative amounts of these interactions of the molecule in the layer A will be proportional to their probabilities, and thus, in the simplest case, also proportional to the number of the molecules of kind 1, respectively kind 2 in the layer B, that is, to N_1 and N_2. The relative amount of the interaction between the two layers A and B generated by the total number of molecules of kind 1 is then again proportional to N_1, and thus amounts to $(N_1z_1+N_2z_{12}).N_1$. Similarly, that of the molecules of kind 2 amounts to $(N_2z_2+N_1z_{12}).N_2$. If z denotes the total interaction, we may thus write:

$$z=N_1^2z_1+2\,N_1N_2z_{12}+N_2^2z_2\,;$$

and as we may put $N_1+N_2=1$,

$$z=N_1^2(z_1+z_2-2z_{12})+2N_1(z_{12}-z_2)+z_2 \qquad (1)$$

The dissipation of energy occurring when the two layers A and B are sliding over each other (as in laminar flow) results from their interaction. In other words, the internal friction must be some function of z. Dolezalek[1] assumed $z=\eta$, but his assumption does not give results in agreement with the experimental data. For reasons which will be stated elsewhere, we have to put $z=\log \eta$, and thus, from (1)

$$\log \eta = N_1^2 . \log \frac{\eta_1 \eta_2}{\eta_{12}^2} + 2N_1 . \log \frac{\eta_{12}}{\eta_2} + \log \eta_2 \qquad (2)$$

On the other hand, Guzman has pointed out, and Sheppard[2] recently emphasized, that log η represents a work-function, and thus (2) represents an energy relationship.

This relationship contains only one constant, namely η_{12}: the coefficient of internal friction for molecules of two different kinds. This coefficient should be used in the calculation of diffusion.

Equation 2 fits the data, determined by Kendall and Monroe[3], with fair accuracy; especially the system benzylbenzoate–toluene, in which case the interpolation formulæ hitherto employed gave very unsatisfactory results (see accompanying table). The same holds for the system hexane–carbontetrachloride.

We obtained by equation 2, again from the data of Kendall and Monroe, for the viscosity of naphthalene dissolved in benzene or in toluene, at 25° C. 2·19 and 2·24 centipoises respectively. The values calculated by Kendall and Monroe differed by more than 20 per cent in the two solvents, as in the case of diphenyl, while we obtain, from the same data, 3,740 centipoises in each case.

N_1	η observed (K. and M.)	η calcul. (K. and M.)	η calcul. (equat. 2)	Difference (K. and M.)	Difference (equat. 2)
				Per cent	Per cent
0 000	0·552	—	0·552	—	0
0·2367	1·183	1·362	1·15	+ 15 1	− 2·6
0·4261	2·015	2·399	2·01	+ 19·1	− 0·4
0·6502	3·614	4·182	3·64	+ 15·7	+ 0·7
0·7890	5·080	5·645	5·15	+ 11·1	+ 1·5
0·9002	6·660	7·024	6·67	+ 5·5	+ 0·6
1·000	8·450	—	8·45	—	0
η_{12} = 2·75 centipoises					

N_1 = mole fraction of benzylbenzoate, in toluene.

The same line of reasoning is being applied to a number of related problems. It seemed, however, worth while to publish these first results.

Points from Foregoing Letters

PROF. H. MUNRO FOX shows that the rates of cleavage of sea urchin eggs are adapted to the temperature of the seas in which they live. For a given rate of cleavage, a higher temperature is necessary in a certain Mediterranean species than in an English species of the same genus; and the same phenomenon occurs within another single species in different latitudes.

Support for Helmholtz's theory that the elements responsible for the initiation of electrical ('action') potentials in the inner ear are 'resonant structures', is adduced by C. S. Hallpike, Prof. H. Hartridge and Dr. A. F. Rawdon-Smith. They find by means of oscillograph records that a 180° phase change in a stimulating tone produces a 'silent period' in the auditory tract potential. No such silent period is observed in the cochlear response, though the phase change is recorded.

Mathematical considerations of the problem of phase transitions between liquids and crystals lead Dr. L. Landau to the view that a Curie point line (with jumps of specific heat, on melting) is not possible, but that there is a possibility of a continuous transition, without a jump in the energy, at a single point in the pressure-temperature plane.

The emission of beta-rays (electrons) from metals during bombardment with fast deuterons is reported by S. Kikuchi, H. Aoki and K. Husimi. There is no residual activity after the bombardment, and the authors consider that the observed effect is due to new types of interaction of the neutron with atoms.

A curve showing the scattering of X-rays ($K\alpha$ rays of molybdenum) by orthophosphoric acid (containing 1 per cent of water) is submitted by J. T. Randall. The author states that this is almost identical with that for sulphuric acid and, in view of the known rigid tetrahedral nature of the SO_4 and PO_4 groups, he intends, by means of a Fourier analysis of the curves, to deduce the distribution of matter in those liquids.

The specific heats of water and of heavy water at various temperatures between 15° and 45° C. have been calculated by Prof. A. Ferguson and A. H. Cockett by determining the electrical power needed to hold the temperature of a calorimeter and its contents stationary at different temperatures above the surrounding medium.

If glucose is administered to rats from which the adrenal glands have been removed, sodium and water diffuse into the intestine producing diarrhœa. The effect may be lethal, but it can be inhibited by giving simultaneously sodium salts. Prof. F. Verzár and L. Laszt, reporting these results, state that they may be related to the previously observed effect of vitamin B_2 on adrenalectomized rats.

Further experiments by Prof. B. C. Guha and B. Ghosh confirm their previous findings, that rat tissue incubated with mannose, in the presence of a limited amount of air, leads to an increase in the amount of ascorbic acid. This increase, however, does not take place when nitrogen is substituted for air, which explains the negative results obtained by Euler, Gartz and Malmberg.

A. R. Ubbelohde reports that X-ray measurements show the expansion pressures of hydrogen and deuterium dissolved in palladium to differ by about 7 per cent. He concludes that in certain hydrides the hydrogen is probably present in the metallic state, and exerts a considerable expansion pressure on the metal with which it is alloyed.

Research Items

Marriage among Serbian Gypsies

IN a final study of the Serbian gypsies, Dr. Alexander Petrović deals with certain conditions affecting the married state (*J. Gypsy Lore Soc.*, iii, 15, 4). Although monogamy is the rule, polygamy is not unknown, depending upon ability to bear the expense of additional marriages. The orthodox gypsies, however, are forbidden plural marriages by law. Among the gypsies of Rogatika, although they are Moslem, polygamy is rare on account of their poverty. The wealthy nomad tin-smiths as a rule have a plurality of wives. One gypsy aged forty years has three wives; and for these it is the custom that one should remain on duty in the tent for a period of eight days, while the other two go out begging. Only rich Christian gypsies solemnize marriage as soon as the bride is brought home. Usually the bride is kept for a while on trial, especially when she is too young for the priest to marry the couple legally. Others do not marry in order to escape payment, or to facilitate getting rid of an undesired wife. Permanence of marriage depends upon economic conditions. In this there is great difference between towns and villages, and different occupations, as for example, between musicians and factory hands. Begging and high earnings in factories have an appreciable effect on the fidelity of the women; and this is the cause of constant quarrels. Of the men in the villages, only one quarter had been married once only, while the remainder had been married repeatedly. In both sexes more than fifty per cent of the marriages had lasted from one to four months only. As a rule, the last marriage lasts the longest—six years and upwards. While the men in the towns tend to marry at a slightly later age than in the villages, the girls marry quite as early.

Cultural Contacts between India and China

IN *Current Science* (August 1936) an interesting paper appears entitled "The Himalayan Uplift since the Advent of Man: Its Culthistorical Significance" by Prof. B. Sahni. The main idea of Prof. Sahni's paper is to show that cultural contacts between India and China have probably existed since the dawn of human existence; that intercourse between the two countries by direct route across the Himalaya was possible before man conquered the ocean. On the evidence amassed by explorers and observers, it is held that round about Middle Pleistocene time, when the main valley of Kashmir was still occupied by the great 'Karewa Lake', interglacial man of about the same stage of cultural development as Neanderthal or Mousterian man in Europe and as Peking man in the Far East, flourished (*a*) in the plains of the northern Punjab, (*b*) on the shores of the Karewa Lake in the heart of Kashmir, and (*c*) just across the great Himalayan Range. The close cultural contacts between India and China during the historic period are fairly easily explained, as both countries possessed considerable seafaring power in ancient times, whilst the physical endurance of the Buddhist pilgrim mountaineers has become legendary. Palæolithic man had little incentive to travel beyond the necessary distances to provide him with his daily food. Even if he had wandered between the Punjab and Kashmir, it would be difficult to explain his crossing even the lowest pass in the Himalayas. Thus, the importance of the uplift of the Himalayas during the human epoch is evident.

Two-Factor Inheritance in Man

IN the Laurence-Moon syndrome, first described in 1866, mental retardation is accompanied by obesity, hypogenitalism, retinal degeneration with pigmentation, and polydactyly, the last condition alone being visible at birth. Dr. E. A. Cockayne has recently shown that although normal parents may produce affected children, their frequency is too great to be due to a single recessive factor. Dr. Madge T. Macklin (*J. Heredity*, 27, No. 3) has collected from the literature 53 families having a total of 283 children, 112 (or 39·6 per cent) of whom were affected. There is also an excess of affected males. An analysis of the various families leads to the conclusion that the condition is due to the presence of two genes, one an autosomal dominant and the other a sex-linked recessive. The large range of characters affected would also support the hypothesis that more than one gene was probably concerned. Cousin marriages are also found to be more frequent in these pedigrees than in the ordinary population.

Diseases of Birds

THE Biological Institute of São Paulo, Brazil, has published a valuable treatise upon the diseases of birds, compiled by J. Reis, P. Nobrega and A. S. Reis ("Doenças das Aves, Tratado de Ornithopathologia", pp. 469). The thoroughness with which the compilation has been made may be judged by the extent of a few of the sections of the work: virus diseases, 91 pages; various forms of mycetosis, 142 pages; protozoan diseases, 78 pages; diseases of nutrition, 21 pages. The book is well illustrated by photographs and diagrams.

American Flies of the Genus *Psychoda*

THE family Psychodidæ has been the subject of great attention, particularly with reference to the blood-sucking genus *Phlebotomus*, while the non-hæmophagous forms of the genus *Psychoda* have attracted much less notice. Both in Europe and North America the species *Psychoda alternata* and *P. phalænoides* breed in vast numbers in sprinkling filter beds. At times they issue in such swarms that it is impossible to work in the vicinity without the creatures entering the mouth and nose. No adequate evidence, however, has been presented with regard to their functioning as disseminators of disease germs. In the *Philippine Journal of Science* (59, No. 1, 85; 1936), Mr. F. del Rosario contributes a detailed revisional study of the genus, dealing with the American species. Since Haseman's work, published in 1907, little attempt has been made at a taxonomic study of the group in so far as North America is concerned.

Crustacea from the *Godthaab* Expedition

DR. K. STEPHENSEN has extended our knowledge of the distribution of many species of Crustacea from the waters between Greenland and Arctic America north of the east corner of Labrador in his two papers "Crustacea Decapoda" and "Crustacea Varia" (The *Godthaab* Expedition 1928. Leader: Eigil Riis-Carstensen. Meddelelser om Grønland, Bd. 80. No. 1, 1935 and No. 2, 1936). The decapods are here divided into bottom and pelagic forms, the bottom forms into Arctic, Boreal and Atlantic, the pelagic forms into Arctic and Atlantic. The Arctic forms are again sub-divided, the whole arrangement being based mainly on the summary by Holsten (1916), and maps of the distribution of the species are given. Specially interesting is the distribution of *Bythocaris leucopis* and *B. payeri*, the former belonging to much deeper water than the latter, *Ephyrina benedicti* new to northern waters, *Hymenodora glacialis* and *H. gracilis*. The finding of the two *Bythocaris* species and *Hymenodora glacialis* proves the identity of the Arctic deep-sea faunas north of the ridge east and west of Greenland. Most useful in the decapod paper are descriptions of larval forms, many of which were hitherto unknown. The larvæ of *Chionoecetes opilio* and of *Hymenodora glacialis* are described for the first time, and a beautiful new *Eryoneicus* (*E. groenlandicus*) which is certainly a larval form. There are also numerous suggestive notes on other larvæ not definitely fitted into their respective places, but the probable adults in most cases being given. In "Crustacea Varia" are included the groups not recorded in the other *Godthaab* Expedition papers.

Anther Smut of Carnations

DR. H. L. WHITE has directed attention (*Gard. Chron.*, Oct. 3) to the prevalence of the rather unique disease caused by the fungus *Ustilago violacea*. This organism can attack a large number of Caryophyllaceous hosts; but its effects are not usually noticeable until dark-coloured smutty spores are produced upon the anthers. The disease has probably occurred frequently where carnations have been grown in glasshouses; but it has recently attained rather more serious proportions. Numerous side shoots appear on an infected plant, before spores are produced. This feature favours control, for such shoots can be removed before they become a source of further infection, and they should also be rejected in the selection of shoots for purposes of propagation.

The Plant Chloroplast

PROBABLY no more important physiological unit can be chosen for study than the green chloroplast which is usually regarded as the seat of the photosynthetic process, yet an interesting paper by Kogane Kiyohara (*J. Fac. Sci., Tokyo*, Sec. 3, Botany, 4, Pt. 5) makes it clear how little definite information we have as to its structure and life-history. From a study of 262 species of flowering plants, he finds that the plastid is always a round object, spherical or a more or less flattened disk, with a diameter of about 5μ. Treatment with silver nitrate or osmic acid reveals a blackened ring in this disk; the starch formation is associated with the non-blackening central region of the plastid. In *Hydrilla verticillata*, in the growing cells of the leaf-base, clear cases are figured of the elongation and subsequent division of such disk-like chloroplasts, an observation which confirms the views of Schimper and Meyer. But a more controversial point is raised by the author's observation that whilst certain fixatives, particularly Kolatchev's and Carnoy's, show round typical chloroplasts in meristematic cells, the normal chondriosome fixatives distort these structures—which appear to be fluid in these meristematic cells—into typical thread-like chondriosome structures, so that the author concludes that the genetic connexion of chondriosomes with chloroplasts and indeed the presence of chondriosomes in plant cells is not as yet established.

Direct Oxidation of Soil Humus

DECOMPOSITION of organic matter in the soil leads, amongst other things, to the production of nitrates, which may be used directly by growing crops. Mr. C. B. Greening has suggested (*J. Roy. Hort. Soc.*, 61, Pt. 9; Sept. 1936) that this change might be brought about directly by oxidation of the organic matter with potassium permanganate. Lawns and several garden crops have benefited by the application of a dilute solution of this substance. Experiments quoted in the paper are on a very small scale, but larger trials are in progress at Wisley. The production of large quantities of nitrate in the soil is not to be desired for most crops, and any quick process of oxidation would deplete the soil of its reserves of organic matter, but the new process may well find application in some particular technique of horticulture, and in any case it would provide a new item of intellectual equipment for the scientific gardener.

Continental Motions

IN the October issue of the *Journal of the Franklin Institute*, Dr. Ross Gunn, of the United States Naval Research Laboratory, calculates by an approximate method the gravitational force on the North American continent due to the probability that the density of the earth's outer shell under the Pacific Ocean is about two per cent greater than under the continents. He finds it is equivalent to a slope downwards towards the Pacific of 1 part in 15,000. He is not prepared to say whether under these conditions the continent is at present at rest, but he considers that the presence of mountain ranges bordering the Pacific shows that in the past these forces have produced crushing and folding of the crust. For the North Atlantic he calculates these forces as being about half those of the Pacific. He considers these unsymmetrical distributions of density throughout the earth's crust support the theory that satellites were produced by fission due to tidal forces in the parent planet when in the liquid state.

Diamagnetism and Particle Size

INVESTIGATIONS on the susceptibility of substances in the form of small particles, produced by colloidalization or cold working, have revealed, in many cases, an apparent dependence of diamagnetism on particle size. There has been considerable controversy as to whether this is a true surface effect or, as has been maintained by Bhatnagar, simply an impurity effect, due to the larger surface of finely divided material facilitating such processes as oxidation and hydration. A critical survey of the subject has recently been made by Prof. H. Lessheim (*Current Science*, 5; 1936). He shows that the theoretical arguments which have been advanced in favour of a surface effect are certainly inadequate to account for the magnitude of the changes observed, and gives a detailed discussion of the experimental work on different substances. In many cases, as with bismuth, antimony and lead, the change in diamagnetism is due to the formation of surface layers of oxides; when the oxide is chemically removed, or when sufficient care is taken to exclude the possibility of oxidation during the preparation, the finely divided material has the same susceptibility as the material in bulk. Carbonization and the adsorption of gases may produce similar effects. Changes in diamagnetism are often associated with changes in crystal structure, and in some cases such changes may be brought about by the processes by which the fine particle material is produced. Where such changes can be excluded, Lessheim concludes that there is no definite evidence of an appreciable change in diamagnetism due simply to change in particle size.

A New Oxide of Phosphorus

THE discovery of a peroxide of phosphorus, with the formula PO_3 (or possibly P_2O_6) is reported by P. W. Schenk and H. Platz (*Naturwiss.*, 24, 651; 1936). When a mixture of phosphorus pentoxide vapour and oxygen is admitted to a discharge tube under a pressure of about 1 mm., and the discharge is passed, a bluish-violet product collects behind the discharge zone. The substance may be kept for about a day at ordinary temperature and in the absence of moisture. In aqueous solution it liberates iodine from potassium iodide. Using this reaction as a method of estimation, it is found that the bluish violet substance contains about two per cent of the new peroxide.

Theory of Photographic Development

EXPERIMENTS in favour of their adsorption theory of photographic development have recently been carried out by A. J. Rabinovitsch and S. S. Peissachovitsch (*Acta Physicochim. U.R.S.S.*, 4, 705; 1936). The conditions obtaining in the exposed photographic plate may be imitated by mixing a colloidal solution of silver bromide to represent the nuclei of silver bromide, and a silver sol, to represent the nuclei of silver present in the exposed plate. Addition of alkaline hydroquinone, metol, adurol, and other photographic developers causes a rapid blackening of the mixture. The colloidal silver may be replaced by platinum, gold, or copper sols, and the same development is obtained. If, however, Bredig's silver sol, or sols of palladium, bismuth, the hydroxides of aluminium, and iron, titanium oxide, or activated charcoal are substituted for silver, development does not occur. It has been shown that the sols which may replace silver and give similar results are those which will adsorb hydroquinone and other developers, whilst those which inhibit development are sols which do not adsorb the developer. By a study of cataphoresis and other experiments it is shown that the particles of the added silver sol are intimately linked with the silver bromide particles. If gelatin is added to the silver bromide sol before the addition of the silver sol, no development of the mixture occurs. Many other phenomena of importance in the theory of photographic development can be examined by means of the above system, including the effect of size of silver particles, hydrogen ion concentration, and addition of various chemicals, such as sodium sulphite and potassium bromide, on the rate of development.

Numerical Methods in Late Babylonian Astronomy

PROF. OTTO NEUGEBAUER, of Copenhagen, has published in *Osiris* (2, part 12, 517) what is intended to be the first of a series of studies of Naburimannu's and Kidinnu's systems of the solar and lunar motions, to be continued elsewhere. The texts used are the same as those used by Kugler in his epoch-making work, "Die Babylonische Mondrechnung" (1900) in one of which Prof. Neugebauer has introduced a number of corrections from a British Museum photograph. His interest is in the arithmetical methods used in these texts, especially in the length of the day and the anomalistic motion of the sun. His exposition is remarkably clear, and he finds, as Kugler found before him, that in the system now known as Naburimannu's, the sun is given two uniform velocities each lasting half the year, and the length of the day is made to increase at a uniform rate from one solstice to the other and to diminish at the same uniform rate in the opposite half of the year, while in Kidinnu's system, instead of uniform motions changing suddenly in amount or direction, we have a uniform change between two extremes in the rate of change. In other words, with Naburimannu, first differences are constant between limits, while with Kidinnu second differences are constant between limits. These methods, as Prof. Neugebauer has illustrated elsewhere, are very characteristic of Babylonian mathematics.

Multi-Cylinder Steam Turbines

THE English Electric Co. so early as 1923 constructed multi-cylinder turbines, but the development of this engine in recent years is due to the great increase in steam pressures and temperatures, and in the outputs of turbines. In the *English Electric Journal* of September, Mr. J. T. Moore describes the large multi-cylinder turbines now made by the E.E.C. The multi-cylinder turbine has the great advantage that the high pressures and temperatures are confined to a comparatively small section of the turbine. The high pressure cylinder which the steam first enters can be made of symmetrical and very simple design. The casting is therefore free from residual stresses, and high temperatures cause little distortion. It is admirably suited for work in large power stations where sudden changes in the electrical load cause fluctuations in temperature. Recent engines are of the three-cylinder type, the steam after passing through the high-pressure cylinder passing into the much larger intermediate cylinder and finally into the still larger low-pressure cylinder which works at much lower temperatures. Mr. Moore points out that with very high initial steam pressures and temperatures, the casing of the high-pressure cylinder, which is subjected to the highest temperatures, could be made of molybdenum cast steel. The intermediate-pressure cylinder, which is subjected to more average temperatures, could be made of normal cast steel and the low-pressure cylinder of close-grained cast iron. Multi-cylinder turbines have proved their worth in service. For example, a 25,000 kw. set in Sheffield was in operation for 93 per cent of the greatest possible time for a year at an average load of 86 per cent of the total. A 30,000 kw. set at the West Ham power station has generated over five consecutive years 75 per cent of the total output of the station.

Recent Advances in Horticultural Research

EAST MALLING RESEARCH STATION

THE annual report of the East Malling Research Station, Kent, for 1935, was published a short time ago (4*s*., including postage, from the Station). Administrative details are set forth in a supplementary report, leaving the main volume for the presentation of research findings.

The third section is the largest in the volume, and portrays the results of research work in progress. J. Amos, T. N. Hoblyn, R. J. Garner and A. W. Witt describe their studies in incompatibility between stock and scion, and Misses A. B. Breakbane and M. E. Renwick have also contributed to a solution of this problem by issuing a preliminary report upon the internal structure of root wood of stock and scion varieties. H. M. Tydeman reports further investigations in the root systems of apple trees, W. S. Rogers has considered the effects of soil moisture upon plant growth, using an ingenious vacuum moisture meter, and M. C. Vyvyan has a note on the moisture content of the stems of different rootstocks. Spring frosts at East Malling, from 1915 until 1935, are described by T. N. Hoblyn, whilst H. C. Chapelow and H. M. Tydeman deal with more general weather conditions.

Injection as a method of supplying deficiency of particular nutrients has been studied by W. A. Roach, who describes leaf injection, and by J. Hearman, B. F. Goodman Levy and W. A. Roach, who write on stem injection. Dr. H. Wormald has papers upon silver-leaf disease, *Verticillium*-wilt of hops, and a slime fungus on strawberry leaves, in addition to a general report on plant diseases. F. H. Beard, Dr. H. Wormald and W. A. Roach have investigated the bacterial canker of plum trees in relation to nutrition. Entomological investigations are concerned with the mites of hops and fruit trees, and the transmission of strawberry 'yellow-edge' virus, by Dr. A. M. Massee, and "Studies of Impregnation of Tree-banding Materials, by Dr. A. M. Massee and R. M. Greenslade. W. Steer has some "Observations on the Codlin Moth", whilst M. H. Moore, H. B. S. Montgomery and Dr. H. Shaw report upon field trials of several new fungicides and combined washes.

Section 4 of the Report is devoted to bulletins of interest to fruit growers. Here the progressive grower is advised upon "The Rapid Conversion of Unprofitable Fruit Trees by Grafting" (R. J. Garner), "Some Observations on the Roots of Fruit Trees" (W. S. Rogers), and "Some Notes on One Year's Experience with a Gas Store", by A. C. Painter. There are also articles on frost damage by W. A. Bane, the use of derris-root insecticide (W. Steer), upon walnut culture, by Miss J. B. Hamond, and on growing healthy raspberries, by R. V. Harris.

LONG ASHTON RESEARCH STATION

The staff of the Agricultural and Horticultural Research Station at Long Ashton, Bristol, is to be congratulated upon the extensive results of research work portrayed in the Station's Annual Report for 1935. A rather severe financial loss was sustained when the incipient crop of fruit was ruined by frost in May of last year, but this does not seem to have curtailed the volume of investigation. G. T. Spinks and Dr. T. Swarbrick have made a virtue of necessity, and have described the frost and its effects in great detail. Dr. Swarbrick has also a progress report of investigations into the varieties of rootstocks for plum propagation.

Reports of work on plant pathology occupy the greater part of the volume. Descriptions of new or specific diseases and pests including a malady of strawberry resembling the American 'crimp' (L. Ogilvie and C. R. Thompson), new virus diseases of the tomato, and *Sclerotinia*-wilt of the hop, by L. Ogilvie, and *Melasoma Populi*, a chrysomelid pest of the basket willow, by Dr. H. G. H. Kearns. The incidence of reversion in seedling black currants and in clones derived from them is described by E. Umpleby and T. Swarbrick. New work has been done upon control of the woolly aphid (H. G. H. Kears and E. Umpleby), of flea beetles (Dr. C. L. Walton), and upon the effects of calcium cyanamide on pea and potato sickness by C. L. Walton, L. Ogilvie and P. W. Brian. Drs. H. G. H. Kearns and H. Martin have investigated the action of lauryl rhodanate as an egg-killing wash, and they have had the co-operation of R. W. Marsh in an investigation of combined washes, designed to eradicate a number of pests or diseases.

A number of papers on cider and fruit products include "Low-temperature Keeving of Cider", by V. L. S. Charley, "Experiments on the Improvement of the Juice from Culinary and Dessert Apples by Maceration with Pressed Bittersweet Pomace", by P. T. P. Pickford, and "Investigations on Fruit Products" by V. L. S. Charley. The last-mentioned paper includes several useful descriptions of modern methods of making fruit syrups, squashes and wines.

The investigations on willow culture are represented by a paper by H. P. Hutchinson, discussing the planting of the cricket bat willow on sewage farms, and a very gratifying report from the Berkeley Square Advisory Centre is also included in the volume. This organization has answered more than 6,500 inquiries, as against 4,813 in 1934, and this in spite of an increased amount of advisory work handled directly by the Long Ashton Research Station.

CHESHUNT RESEARCH STATION

The twenty-first Annual Report, for 1935, of the Cheshunt Experimental and Research Station, Turner's Hill, Cheshunt, Herts, sets forth the results of a very considerable volume of original investigation. The director, Dr. W. F. Bewley, reviews the whole work of the organization, and also discusses the practical value of experiment and trial work in progress under his ægis. This includes such useful features as the use of straw to provide a more efficient distribution of heat in soil sterilization, the employment of peat as a surface rooting medium for tomatoes, and the provision of soil heat. Mr. P. H. Williams has a very interesting paper on the overwintering of a perennial *Phragmidium* rust of the rose. Dr. H. L. White describes the 'damping-off' disease of lettuce, the crown-rot of rhubarb, the stem-rots and *Verticillium* wilt of the carnation. A disease of cultivated heaths has been studied by Miss E. Oyler and Dr. Bewley, who find that it is caused by the fungus *Phytophthora Cinnamomi*. New work on virus diseases by Dr. G. C. Ainsworth includes the description of 'bushy-stunt' of tomato, a disease of the 'fern-leaf' type upon the same host, fig mosaic, and a virus disease of water-cress. Mr. E. R. Speyer has turned the entomological investigations to a study of various injuries caused by thrips, particularly on carnations and roses. The uses of the new spray fluids, copper oxychloride, copper salicylanilide, and cuprous cyanide, are discussed by Mr. W. H. Read, whilst Dr. O. Owen has investigated the use of chlorate weed killers, and other problems. In the realm of physiology, Messrs. B. D. Bolas and I. W. Selman have studied the movement of assimilate in seedling tomato plants, and Mr. D. W. Goodall considers some of the causes of variation in growth-rate of the tomato. Finally, a modest report from the Station's Extension Officer, Mr. O. B. Orchard, shows that the important work of translating research findings into practical technique receives the energetic attention it deserves.

The work of the Station is made possible by the Nursery and Market Garden Industries' Development Society, Ltd., and it is encouraging to note that an endowment fund has now been opened. The Society's late president, H. O. Larsen, has performed his last act of generosity to the Station by a bequest of £2,000.

British Thunderstorms

IT is a fortunate circumstance for British climatology that there has never been a lack of scientifically-minded laymen ready and willing to co-operate in large-scale observational work. The late G. J. Symons and his successor, Dr. H. R. Mill, found it possible to enrol more than five thousand voluntary observers of rainfall. Quite recently, as we learn from the annual report of the Director of the Meteorological Office, more than eight hundred observers responded to an invitation to co-operate in a special investigation of mist and fog.

Mr. S. Morris Bower began his work on summer thunderstorms in 1931, when he invited co-operation in a project to record storms occurring between the months of April and September. Prior to that date, he had been engaged on a census of winter thunderstorms, following earlier work on similar lines by Capt. C. J. P. Cave. Nearly a thousand observers assisted Mr. Morris Bower in 1931; in 1934 the number of observers had risen to 1,254[*]. That is a very large number of persons to take part in a purely private enterprise, and it affords remarkable evidence of the extent to which scientific zeal is disseminated among the general population. We may conclude that the enthusiastic private investigator is assured of public support in a piece of work that seems worth doing, notwithstanding the official meteorological service, to the maintenance of which the observers themselves have to contribute as tax-payers.

That leads us to reflect upon the relationship which should exist between the official service—represented by the Meteorological Office—and a private organization such as that maintained by Mr. Morris Bower. So far as climatology is concerned, the function of the Meteorological Office is to collect and preserve for public use an adequate number of weather records from all parts of the British Isles. In pursuance of that aim, it maintains about fifty official stations; the records from these are supplemented by about three hundred co-operating 'climatological' stations, most of which are maintained by local authorities. The principle of voluntary co-operation has, indeed, been a fundamental feature of British climatological work since the earliest days of the Meteorological Office. The 350 official and voluntary stations suffice for the general purposes of climatology; but they do not suffice for an intensive study of the geographical distribution of a particular element such as rainfall, fog or thunderstorms. Thus we have to recognize the need for a closer network of stations when problems of this character arise, and the need is best met by an *ad hoc* organization. The role of the special organization is to amplify and extend the work of the official climatological organization, just as the three hundred co-operating climatological stations amplify and extend the work of the fifty official stations. There is clear evidence that Mr. Morris Bower and his collaborators have fully appreciated this aspect of their work. It is of interest to note that all the observers who participated in the special investigation of fog referred to above, and a large proportion of Mr. Morris Bower's thunderstorm observers, are drawn from the ranks of the five thousand or so rainfall observers of the British Rainfall Organization, which thus forms as it were a 'reservist' body of meteorological workers who may confidently be relied upon to furnish volunteers for any special piece of work.

To return to the report under notice—it is a well-produced account of the summer thunderstorms of 1933 and 1934, illustrated with numerous charts (many in two colours), photographs and diagrams. In addition to the charts and statistics relating purely to the incidence of thunderstorms, there are sections on damage to house property, trees struck by lightning (by Mr. S. T. E. Dark) and on damage to wireless installations (by Mr. Ralph A. Price). The present writer feels that the report is rather lacking in details of individual storms. In "British Rainfall" one finds a good deal of information about the rainfall occurring in noteworthy thunderstorms, and one would like to be able to turn to Mr. Morris Bower's report in order to find the corresponding information about the incidence of thunder and lightning. Such information exists in the form of manuscript records, and it is to be hoped that it will find its way into the report as funds allow. Meanwhile, Mr. Morris Bower and his collaborators are, nevertheless, to be congratulated on the results of their ambitious undertaking.

E. G. BILHAM.

---

Applications of Mechanical Science

TWO pamphlets recently issued by the Association of Engineering and Shipbuilding Draughtsmen (London: The Draughtsman Publishing Co., Ltd.) may be cited as indicating the continued process of translating the work of investigation and research into the most practical terms. One of these is Part 2 of "The Application of Influence Lines to the Stress Analysis of Beams and Lattice Girders" by R. McCrae (2*s*.), of which Part 1 dealing with beams was noticed in NATURE of May 23, p. 861. The part now published treats of lattice girders and deals with various types of loading.

While a lattice girder is, as a whole, subjected to bending and shear, these actions produce in its individual members conditions of tension and compression which vary according to the loading. It follows, then, that the treatment differs from that of beams, where the influence line diagrams represent the bending moments and shear forces due to a unit load at any point in the span. Despite this difference, however, the variation in the treatment here expounded is more a matter of detail than of principle, and for those who have much work of this kind to do the method offers useful advantages over the more formal modes of analysis.

The second pamphlet referred to is "Mechanical Tests for Engineering Materials" by A. M. Roberts (4*s*.), a subject of wider appeal. The development of mechanical testing has been very rapid in recent years, and an elaborate and comprehensive technique has been devised to deal with different materials and to meet widely varying requirements. For the draughtsman it is advisable that he should be able to indicate or specify suitable acceptance tests for the materials he has incorporated in his designs, and it follows that he must be in a position to decide which methods of testing are most appropriate to each machine or structural detail, so that he can ensure its satisfactory performance in service.

It is to meet this particular requirement that the pamphlet has been prepared, and it explains, in suitably condensed form, the methods and purposes associated with the more usual forms of tests. Tensile, bend, hardness and impact tests are described and elaborated in detail, and the relation of the part under consideration and its service conditions to the appropriate test procedure is discussed; while, in some cases, suggestions are included as to the method of approach in designing for service under static, dynamic or other special conditions. It will thus be apparent that the point of view of the author is different from that of the usual writer on material testing, and his information will supply a real need in the case of many who as designers, buyers or in other capacities are not directly brought into contact with the technical processes of testing, yet require to possess such knowledge as is set out here.

Sir Charles Parsons Memorial

ACTING in conjunction with various engineering institutions, the Royal Society has made arrangements for honouring the memory of Sir Charles Parsons, whose name is best known in connexion with his invention of the compound steam turbine. These include a memorial in Westminster Abbey, a memorial library in London House, and an annual lecture which, each fourth year, will be delivered on the north-east coast—the scene of Parsons' major activities—and in the intervening years is to be given in London.

This year's lecture, the first of the series, was given before the North-East Coast Institution of Engineers and Shipbuilders at Newcastle-on-Tyne on Friday, November 6, and took the form of a personal appreciation by Sir Frank Smith, who is one of the secretaries of the Royal Society and also secretary of the Department of Scientific and Industrial Research. On the same day, the Institution inaugurated a special exhibition to illustrate the work of Parsons, the wide range of his scientific interests and the fertility of his inventive powers.

In introducing his subject, Sir Frank Smith referred to the influences which heredity and the scientific environment of his youth, as a son of that distinguished man of science, the third Earl of Rosse, exercised upon the course of Parsons' life and work. Those who saw the workshops at Birr Castle have testified to the profound impression made on them by the installations of machinery and furnaces in the towers of the old building and by the matchless self-possession and unfailing resources of the master mind and guiding hand. The son, who had received his early training there, retained throughout life a keen interest in optics and astronomy, and in his later years was attracted by the same astronomical problem as had earlier engrossed his father, namely, that of producing reflecting mirrors of great size. Their construction in glass did not appeal to him as an engineer and, holding the view that, in the future, larger sizes than 200 inches would be required, he planned that they should be made of steel and had arranged to build a small mirror in sections to test his ideas in practice.

When Parsons went down from Cambridge in 1877, the prevailing feeling about the steam engine was that the limit of useful improvement had been reached. Newcomen's engine required 25 lb. of coal per horse-power hour; Watt had reduced this figure to 5·5; and the amount had in the succeeding years been brought down to about 2 lb. Undaunted by those views, Parsons pressed forward with his invention, and in 1884 took out his first patent, the claims of which show to-day how clearly he realized the future of his engine. The novelty he introduced lay in the method by which he utilized the expansive force of steam. His first turbine, which was of the double-flow type, was made in the same year, and is now to be seen in the Science Museum. It is suggested that, in this invention, Parsons was inspired by three main influences: the first, his love of attempting what others thought impossible; the second, his exceptional knowledge, at that time, of thermodynamics and the properties of steam; and the third, the advent of the electric dynamo for power generation.

The earliest turbines were designed for driving electric dynamos, and from 1888 the installation of turbo-generators steadily increased, the coal consumption being brought down to 0·7 lb. per horsepower hour. In 1894, Parsons planned the *Turbinia*, an experimental vessel to demonstrate the capabilities of the turbine for ship propulsion, and, in 1897, the Admiralty adopted the method. Trials made a few years later established the efficiency, economy and higher speed possibilities of this new motor for naval purposes. In the merchant service, the Clyde steamer *King Edward* led the way, and by 1904 such important vessels as the *Lusitania* and *Mauretania* were fitted with turbine engines—a remarkably rapid success.

The Parsons Exhibition, which is being held at the Municipal Museum of Science and Industry, Newcastle-on-Tyne, and was opened by the Right Hon. Lord Rayleigh, is well described in the "Catalogue of Parsons Exhibition, November 1936–January 1937" (London: E. and F. N. Spon, Ltd. 6*d*.). In it are to be seen numerous models of the turbine at the different stages of its development—Hero's, Branca's, Wilson's and several machines made by Parsons. There are many details of blading, bearings, governors and other parts, and some of the instruments and apparatus used by Parsons in his experiments. A series of coloured sectional drawings and photographs illustrates the development of the turbine from 1894 down to 1936. The other inventions of Sir Charles Parsons are also represented, and there are examples of silvered glass reflectors, optical instruments and experimental disks made under his supervision, to round off this notable appreciation of the range of practical inventiveness of one man who, in the province which he made his own, exercised a profound influence upon his time.

Educational Topics and Events

CAMBRIDGE.—J. F. Brock, Trinity Hall, has been appointed assistant director of research in medicine. J. S. Baxter has been appointed University demonstrator in the Department of Anatomy.

At Gonville and Caius College, Dr. V. J. Chapman, formerly scholar of Pembroke College, has been elected to an unofficial Drosier fellowship.

In accordance with its usual practice, Trinity College announces the offer of a research studentship open to graduates of other universities who propose to go to Cambridge in October 1937 as candidates for the degree of Ph.D. The value of the studentship may be as much as £300 a year. Candidates must not have reached the age of twenty-six years before May 1, 1937. The College also offers Dominion and Colonial exhibitions to students of Dominion and Colonial universities who wish to go to Cambridge next October as candidates for the degree of B.A., M.Litt., M.Sc. or Ph.D. These exhibitions are of the titular value of £40. A candidate for a studentship or exhibition should apply through the principal authority of his university, and his application should reach the Senior Tutor (from whom further particulars may be obtained) by May 1, 1937.

OXFORD.—The Rolleston Memorial Prize for 1936 has been divided between J. A. Moy-Thomas, lecturer of Christ Church, and B. G. Maegraith, fellow of Exeter College.

The Theodore Williams scholarship in physiology for 1936 has been awarded to R. T. Campbell of Magdalen College.

Lord Halifax, chancellor of the University, will preside at a meeting of Congregation on November 24 at which a decree will be promulgated thanking Lord Nuffield for his benefaction to the medical school and describing how it is proposed to make use of it.

ST. ANDREWS.—Under the will of Miss Edith Mary Valentine Scott Lang, the University is offered a bequest of £20,000 provided that it will undertake to supply an astronomical observatory and the necessary instruments. Miss Lang was a daughter of the late Sir Peter Redford Scott Lang, regius professor of mathematics in the University for forty-two years, who was desirous that a lectureship in astronomy should be founded in the University. She directs that the lectureship should be called the Napier lectureship in astronomy, in memory of Baron Napier of Murchiston. From the reading of the will it would appear that in the event of the acceptance of the £20,000, the university is committed to the building of an observatory and the provision of instruments from funds outside the bequest. The will gives no indication of the destination of this £20,000 if the University does not accept it.

THE next election to Beit fellowships for scientific research will take place on or about July 9, 1937. The annual value of a fellowship is £240, and it is tenable for two years. Fellows will be attached to a department of the Imperial College of Science and Technology. Further information can be obtained from the Rector, Imperial College, South Kensington, London, S.W.7.

THE thirty-seventh annual meeting of the Science Masters' Association will be held in the Physics Department of the University of Manchester on January 5–8, 1937, under the presidency of Dr. J. S. B. Stopford, vice-chancellor of the University. On January 5, Dr. Stopford will deliver his presidential address entitled "Aims of Biology in Education". There will be the usual exhibitions of members' apparatus, etc., and a number of visits to works, collieries, etc., has been arranged. Further information can be obtained from the Annual Meeting Secretary, 15 Norham Gardens, Oxford.

WHEN invitations were issued to universities and scientific and learned institutions to take part in the celebrations in June last at the University of Heidelberg, considerable discussion was aroused in the Press in Great Britain, and as a result the invitations to English bodies were withdrawn. It seems there was little controversy on the subject in the United States, and the Viking Press, Inc., New York, has now published a booklet of 61 pages entitled "Heidelberg and the Universities of America", reprinting the "Heidelberg" correspondence and articles from *The Times* and NATURE; a brief explanatory introduction, signed by Charles C. Burlingham, James Byrne, Samuel Seabury and Henry L. Stimson, states that the publication has been issued so that "Americans may know the grounds of the English refusal" to take part in the celebrations.

Science News a Century Ago

British Surveying in South American Seas

SEVERAL communications were read at a meeting of the Royal Geographical Society on November 14, 1836, some of them relating to expeditions in Kashmir, Australia, South and Central Africa and in British Guiana. The first paper was by Captain R. FitzRoy and was entitled "A Sketch of the Surveying Voyages of H.M.S.S. *Adventure* and *Beagle*, from 1825 to 1836". From the time Captain FitzRoy resumed the surveys in 1831, every mile of the coast from the Rio de la Plata to Cape Horn was closely surveyed and laid down on a large scale, every harbour and anchorage was planned, thirty miles of the Rio Negro and two hundred miles of the Santa Cruz were examined; a chart was made of the Falkland Islands and the whole coasts of Chile and Peru were surveyed. "Traced copies," said Captain FitzRoy, "of the charts of coasts adjacent to Buenos Ayres, of the whole coast of Chili and of the greater part of the shores of Peru were given to the respective governments of those countries before our vessels left their territories, and long before the original documents could reach England." Commenting on this, the *Athenæum* said, "this is, we believe, an instance of liberality without parallel in the whole annals of maritime survey or discovery".

Geology of the Clyde Estuary

IN a paper entitled "On Indications of Change in the relative level of land and water in the Estuary of the Clyde" read to the Geological Society on November 16, 1836, James Smith (1782–1867) said that in the west of Scotland there are two superficial deposits. The lowest, locally called 'till', consists of unstratified clay, mixed with boulders and rarely containing organic remains, while the upper deposit is composed of finely laminated clay overlaid by sand and gravel. In the latter, marine remains of existing species occur in every part of it, but most abundantly in the clay. This stratum he had traced on both sides of the Clyde from Glasgow to Roseneath and Greenock, at points varying from thirty to forty feet above the level of the sea. The lower deposit, the 'till', in his opinion was accumulated by a violent, though transitory, action of a body of water; but the upper was deposited, he thought, at the bottom of the sea, and that there had been a gradual change of level similar to that taking place on the coast of Sweden as described by Mr. Lyell.

Local Botany in Great Britain

ON November 17, 1836, at a meeting of the Botanical Society, Alexander Irvine (1793–1873) directed the attention of members to the importance of local botany. In the course of his paper, he said that 1,500 species of flowering plants occurred wild in Great Britain, of which about two-thirds were to be found within a circle of twenty-five miles around London. He had himself discovered 670 different species within two miles of Hampstead, while within two miles of Croydon he had found no fewer than 900 different species. The species of vascular plants found in Great Britain comprised nearly all those of Lapland and Sweden, three fourths of those of Germany and about three fifths of those of France. (*Athenæum*.)

Fox Talbot on the Integral Calculus

AT a meeting of the Royal Society held on November 17, 1836, Henry Fox Talbot (1800–77) read part 2 of his paper "Researches in the Integral Calculus". The report on the paper said: "Having explained, in the first part of his paper, a general method of finding the sums of integrals, the author proposes in the second place, to apply this method to discover the properties of different transcendents, beginning with those of the simplest nature. With this view, he first shows its application to the arcs of circles and the conic sections; and demonstrates the possibility of finding three arcs, such that neglecting their signs, the sum of two of them shall be equal to the third, though not superposable in any part: an equality which has been hitherto deemed impossible in the ellipse and hyperbola, without the addition of some algebraic quantity".

Study of Physiology

IN a lecture delivered at the Collège de France and published in the *Lancet* of November 19, 1836, M. Magendie criticized as follows the way in which physiology was being taught in almost all the universities of Europe, Paris included: "What is the student taught, what does he hear during a course of physiology, such as we find it at the present day? A collection of theories, one more visionary, if not more absurd than another; a mass of words, and nothing else, collected from antiquated works and thrown before him without the support of a single fact; to be believed on the words of his professor, without a shadow of that material evidence which constitutes the force of every exact science. It is truly extraordinary to observe how even the most elevated minds are led away by the influence of prejudice, and refuse to acknowledge truths so evident as that contained in the following proposition: 'We can only study phenomenally the experimental method; the laws of physiology are revealed in the manifestation of phenomena; ergo, we should submit the phenomena of physiology to the experimental method'."

Medico-Botanical Society

THE *Lancet* of November 19, 1836, gives the following account of the first meeting of this society, which was held on November 9, 1836, under the presidency of Earl Stanhope: "The meeting was a good one. Dr. Sigmond read a very interesting and learned paper on the Early English Botanists and the Progress of the Science of Medical Botany in England. The study of the science may be dated from the reign of Henry VIII, when Dr. Turner published his 'Medical Botany'. After this various works at different periods appeared, though but little order was observed in any of them, and none of them gave the results of the author's experience with the various plants described, but merely stated their virtues on the authority of Pliny or Dioscorides. The first Pharmacopœia was published by the London College of Physicians in May 1618, but it contained so many blunders that a new edition was published in December in the same year. Pharmacopœias were first thought of by Valerius Cordus, a student of Nuremberg. In 1745 Sir Hans Sloane improved the Pharmacopœia greatly by giving to it a description of the various plants used in medicine. It was still further improved in 1788, and in 1809 the names adopted by the French chemists were first introduced."

Societies and Academies

London

Royal Society, November 5.

O. A. Saunders: The effect of pressure upon natural convection in air. Dimensional considerations suggest that natural convection in air should depend upon the dimensionless number $ag\theta l^3 s\rho^2/\mu k$, the effect of which can be found experimentally by varying either the representative linear dimension l, the representative temperature difference 0, or the pressure of the air. Measurements with vertical plane surfaces of four different heights in air at pressures from 0·001 to 65 atmospheres give results which can be expressed satisfactorily in terms of the dimensionless number. Natural convection at higher pressures, up to 1,000 atmospheres, is also discussed. The values of some of the constants are uncertain at the higher pressures, but $as\rho^2/\mu k$ is not appreciably increased by raising the pressure above about 200 atmospheres, and $\mu s/k$ is nearly independent of pressure up to 1,000 atmospheres.

R. A. Bagnold: The movement of desert sand. The motion of sand grains and their reaction on the air stream when wind blew over a thick layer of dry uniform sand on the floor of a wind tunnel was investigated experimentally. The paths of the individual grains were photographed. The wind velocity distribution and the pressure drop were measured during the sand movement and when movement was prevented. At the same time the total flow of sand past various sections of the tunnel was measured directly. The grain motion was found to consist of a series of bounds: the grains rose steeply into the air stream and fell slowly, gathering forward velocity and striking the sand surface with sufficient impact to splash up more grains into the air stream. Irregularities in the grain paths due to internal air movements were undetected. The drag due to the sand movement is measurable, and is a maximum at the height above the surface at which maximum acceleration of the grains takes place. The length of the characteristic path from impact to impact was found in all experiments to be the same as the measured wave-lengths of the ripples formed on the surface.

J. Smiles and H. Wrighton: The micrography of metals in ultra-violet light. Increased resolution of the microstructure of metals has been achieved by the use of ultra-violet radiation. A method of critical illumination used in micrometallurgy and developed for use in high-power visual light systems, so as to reduce glare set up in the optical system to a minimum, has been used. A dispersing system has been incorporated and adjusted to introduce ultra-violet radiation ($\lambda = 2750$ A.) co-axially with the visual light system. Most metals and alloys can be successfully photographed in ultra-violet radiation with increased resolution conforming to the higher equivalent aperture available.

Paris

Academy of Sciences, October 19 (*C.R.*, 203, 697–752).

Paul Lévy: General determination of the limit laws [probability].

Bertrand Gambier: Surfaces of which the asymptotics of one or the other system belong to linear complexes.

David Wolkowitsch: Homofocal quadrics.

Ole Peder Arvesen: Laguerre's solution of the problem of Apollonius.

Jean Chazy: The advance of the node of a planet under the action of a circular ring.

Alexandre Proca: Photons and particles free from charge.

André Fortier: The determination of the viscosity of a gas and Sutherland's constant. Discussion of the effects of the experimental error in the viscosity determinations of the Sutherland constant.

Edmond Rouelle: Some new experiments on the reduction of frequency in an oscillating circuit the coil in which has an iron core.

Pierre Barchewitz and Aurel Naherniac: An automatic recording spectrograph for the near infra-red (6000–9500 A.). The amplifying system allows photo-electric currents of the order of 10^{-15} amp. to be detected: the accuracy of determination of the position of well-defined bands is ± 3 A.

Antoine Goldet: The thermal variation of the electric double refraction of a liquid mixture presenting a critical point of miscibility.

Jacques Rabinovitch: Magnetic rotatory polarization and magnetic double refraction of α-nitronaphthalene in acetone and nitrobenzene solutions.

Mme. Marie Freymann: The absorption spectra of secondary amines in the near infra-red.

Jean Chedin and Mme. Jeanne Cieutat Pradier: The Raman effect and molecular structure of nitric anhydride. The experiments described lead to the conclusion that N_2O_5 exists in two molecular forms. In the gaseous form or in solution in chloroform, carbon tetrachloride or phosphoryl chloride, it is monomolecular. The other form is polymerized, and this is found in the crystals and in the nitric acid and sulphuric acid solutions.

Marcel Ballay: The constitution and structural hardening of austenites with beryllium carbides.

A. E. Favorsky and P. A. Fikhomolow: The synthesis of an asymmetrical allenic molecule of the fatty series by means of an acetylene-allene transposition.

André Barbot: A method of extracting aldehydes and ketones from their bisulphite compounds. In certain cases, the usual methods (acid or sodium carbonate) give rise to inconvenience and reduction of yield. The use of formaldehyde is suggested and shown to possess advantages.

Henry Gault and André Chablay: The action of organic acids on esters. Studies of the reaction velocities of the reversible system acetic acid, methyl palmitate, with and without a catalyst.

Marcel Frèrejacque: The polymorphism of octacetylsaccharose. This acetate is trimorphous.

Georges Dupont and Victor Desreux: Contribution to the study of β-myrcene. Its catalytic hydrogenation. The hydrogenation of myrcene with platinum black as catalyst gives results entirely different from those obtained when palladium black or Raney nickel is used as the catalyst: the mechanism of hydrogenation is not the same in the two cases.

Albert Demolon and Etienne Bastisse: The genesis of clay colloids in the spontaneous alteration of a granite in a rain percolation chamber.

Jacques Fromaget: The stratigraphy of the recent formations of the northern Annamitic chain and on the existence of man in the lower Quaternary of this part of Indo-China.

André Savornin and André Ranarivelo: Observations on a magnetic storm at Ambatoabo (Madagascar).

Emile Thellier : The determination of the direction of permanent magnetization of rocks. An improved method for marking the direction of the piece of rock before removing from the soil for examination in the laboratory.

Pierre Berthault : The specific origin of the potato.

Julien Costantin : Remarks on the preceding communication.

Ad. Davy de Virville : The flora of some Anglo-Norman reefs.

Emile Brumpt : The receptivity of various domestic and wild birds to the parasite *Plasmodium gallinaceum* of the domestic fowl. The transmission of this hæmatozoa by the mosquito *Stegomyia fasciata*.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, November 16

University College, London, at 5.—Mrs. P. Tookey Kerridge: "The Physiology of Hearing and Speech" (succeeding lectures on November 23, 30 and December 7).*

University of London Institute of Education, at 5.30.—Prof. José Castillejo: "Education and Revolution in Modern Spain" (succeeding lectures on November 18 and 25).*

London School of Hygiene and Tropical Medicine, at 5.30.—Prof. W. Bullock, F.R.S.: "The Development of Bacteriology with an Account of some of the Pioneers who made it a Science" (Heath Clark Lectures. Succeeding lectures on November 18, 23, 25 and 27).*

Royal Society of Arts, at 8.—Prof. E. V. Appleton, F.R.S.: "Some Problems of Atmospheric Physics" (Cobb Lectures. Succeeding lectures on November 23 and 30).

Geographical Society, at 8.30.—Sir Eric Teichman: "The Motor Route from Peking to Kashgar".

Tuesday, November 17

Eugenics Society, at 5.15.—(at the Linnean Society, Burlington House, Piccadilly, W.1).—W. T. J Gun: "The Heredity of the Royal Caste".*

Wednesday, November 18

Royal Microscopical Society, at 5.30.—J. E. Barnard, F.R.S., and F. V. Welch: "Microscopy with Ultra-Violet Light".

Thursday, November 19

University College, London, at 5.30.—E. Ford: "The Nation's Fish Supply" (Buckland Lectures. Succeeding lectures on November 26 and December 3).*

Chemical Society, at 8.—Discussion on "Mesomerism in Organic Chemistry" to be opened by Prof. C. K. Ingold, F.R.S.

Association of Scientific Workers, at 8.—(in the Mathematics Lecture Theatre, Huxley Building, Royal College of Science, South Kensington, S.W.7).—Public meeting and discussion on: "Defence and the Responsibilities of the Scientist", speakers to include Prof. S. Chapman, F.R.S., and Air Commodore L. E. O. Charlton.

Friday, November 20

Institute of Chemistry, at 8.—Prof. John Read, F.R.S.: "A Chapter in the Chemistry of Essential Oils" (Streatfeild Memorial Lecture).

Royal Institution, at 9.—H. G. Wells: "World Encyclopædia".

Physique, Nutrition and National Health

THE incursions of the Lords and Commons into regions where the voice of science should be, and is occasionally, heard, are always of interest to the scientific worker. A notable debate of this kind was held on November 10 in the House of Lords on the Government's declared intention to raise the general standard of physical fitness, and especially that of the young. The subject was first introduced by the Chancellor of the Exchequer in an address to the Conservative Party at Margate on October 2, and was afterwards mentioned in the King's Speech to Parliament on November 3. As on neither of these occasions was any reference made to the subject of national nutrition, and as no responsible minister can be unaware of the relation between national nutrition and national health, one can only assume that the Government does not propose to attack the major issue, with all its far-reaching implications.

However, as Mr. Gladstone said, it is always best to take the charitable view, especially in politics, and it may be that the Government took its cue from the recent disclosure that recruiting for the Army has been seriously affected by the large proportion of rejections on medical grounds. In the Lords' debate, this aspect was emphasized by Field-Marshal Lord Milne, who recalled that in 1932 no less than 57 per cent of would-be recruits was refused from this cause, and that about 25 per cent is usually rejected by the recruiting officers prior to medical examination. Lord Milne urged the necessity for improved and extended physical education of a non-military type, and regretted that, outside the Services, there is a great shortage of qualified instructors.

Although it is to some extent fallacious to argue from a section of the community to the whole community—for recruits are not drawn from the better-to-do classes who are well-nourished from infancy onwards and have ample opportunities for regular physical exercise—no one will deny the value of a good physique; but adequate nourishment is of prior importance. This view was well brought out by Lord Horder. Fitness can never be obtained by physical measures, be they educational or recreative; more basic and imperative are food, shelter, air and leisure. The Ministries of Health and Labour, and the Board of Education must continue their present good work; their methods, however, must be intensified and expedited, and more co-operation is needed. Government offices are necessarily departmental: why must they be so compartmental? The national interest must be aroused; and the cost need not frighten us; it would be very small compared with the cost of revolutions elsewhere. So far we have spent nothing on bloodshed, and we have retained the greatest of all our assets—individual freedom. Regimentation is not wanted; if our people are given the modest requirements of security at home and security of sustenance, their sturdy common sense will do the rest. Democracy, and especially a democracy asked to be physically fit, advances on its stomach.

Lord Dawson of Penn asked that the subject be viewed from the wider point of view of eugenics. Although we are to some extent neglecting the laws of sound breeding, and hence must be careful, it would be wrong to say that as a nation we are deteriorating. Inspection of our elementary schools, notably in London, would corroborate this view; but deficiencies do exist, more particularly among adolescents in factories, and are to be seen among hikers and Territorials, who, although they may be good at games, yet possess bodily defects that bode ill for their future health. The boys and girls of to-day may be taller, stouter and heavier than their predecessors, but mere bulk of frame is not evidence of fitness. The demands on our race are greater than ever; and the defects which compel us to take stock of the present situation go deeper than political considerations. By correcting Nature's methods of a high birth-rate and a high death-rate, by allowing the unfit to survive and multiply their kind, we have incurred the heavy responsibility of exercising selection ourselves, so as to prevent the unfit from vitiating the race. While securing for the child of average abilities every opportunity in the limited sphere of usefulness for which it is cast, we should sieve out the fittest at the ages of, say, fifteen and sixteen or seventeen years, and spare no expense in pushing them forward; and at each stage, mind and character must be tested as well as body.

By saving our unfit children we are harming the community, but we are striving to repair the damage by having fewer and fitter children. It is a fact that the smaller families of to-day have a higher proportion of fitter children; and the mothers of those children appear to be better than those of any previous generation. Contraception is very closely related to the infant death-rate. Whereas formerly twelve pregnancies resulted in five children reared, to-day they result in ten; so that unless families are to become impossibly large, contraception must be practised. At the same time, we do not want too small a population; an appeal for adequate parenthood is needed, and would be answered if it were based on reasoned arguments. The inherently unfit, including the 250,000 mental defectives, should be discouraged from reproduction. The medical profession is always being exhorted to think in terms of prevention; why therefore should it not use measures to prevent the birth of children who are not wanted, who are a misery to themselves and their parents, and damaging to the race? To-day doctors dare not offer relief from the dangers of parenthood owing to the operation of a law which was passed centuries ago to prevent maiming as an escape from military service. That law was never meant to apply to any skilled profession, and medical men should be exempted from i scope.

The Earl of Listowel maintained that malnutr tion is the root cause of poor physique; he quote Sir John Orr's findings to the effect that abou half the population is suffering from inadequat nourishment, and stated that increased attentio to sports or physical training can never mitigat the ill effects of a bad diet. The main problem, h said, is how to increase the purchasing power o the working-class family and to reduce the cost o foods that are essential to health.

The discussion is thus seen to have covered wide field and to have been remarkable for th contributions of the two eminent medical me who took part in it. On the whole, perhaps to little attention was given to the underlyin economic aspects of the problems involved. I was, for example, not pointed out that increase physical exercise must entail an increased consumption of energy-producing foods: the huma engine must have more fuel if it takes i more oxygen; and the extra supply of food must be made accessible. The Government fortunately, does not contemplate compulsion but it realizes that "financial aid will have t be considered", though the main burden is to fall on local authorities and on existing voluntary institutions.

Another omission was any reference to the urgent need of a census of distribution and consumption. If, as many believe, adequate nutrition can only be achieved by raising wages or lowering prices, in lieu of Government subsidies and doles in cash or kind, it is of the utmost importance to know the causes and the extent of the wastes that are now alleged to occur in distribution and consumption; and accurate statistical data on these points are seriously lacking. While such a census is being compiled, progress could be made by undertaking some accurate social-economic experiments like that which was carried out last year by the Potato Marketing Board at Bishop Auckland.

Lastly, poverty is one of the main causes of ill-health and poor physique not only because it involves deprivation of certain essential foodstuffs and a bad environment, but also because it imposes a great mental strain upon those who suffer from it. This truth must have been in the mind of Rousseau when he wrote, nearly two hundred years ago, that "Un corps débile affaiblit l'âme".

The Receding Horizon

The Realm of the Nebulae
By Edwin Hubble. (Yale University: Mrs. Hepsa Ely Silliman Memorial Lectures.) Pp. xiii +210 +15 plates. (London: Oxford University Press, 1936.) 12*s.* 6*d.* net.

"THE history of astronomy is a history of receding horizons." So the author tells us in his first chapter, and sets to work to record, in simple language and with much charm, the story of the recent enlargement of the horizon of the visible universe. This is so obviously a task for giant telescopes, that we naturally expect to find that the great bulk of the work has been done at Mount Wilson. Indeed the author himself has contributed the lion's share, but he has gathered round him a group of very able collaborators, and their labours and thoughts have been so interwoven that "the individual often speaks for the group".

It is a chapter of scientific history which has stirred the imagination not only of professional astronomers, but also of the public at large. The greatest popular appeal is undoubtedly made by the immense size of the now known universe, and its corollary—the relative insignificance of our home in space—although it is not easy to see how a further million million-fold increase in the volume of the visible universe can add much to what Galileo had already achieved in 1610. So recently as twenty years ago, many astronomers were inclined to regard the spiral nebulæ as members of the Galactic System, thereby limiting the visible universe to a radius of perhaps 50,000 light years. Dr. Hubble now tells us (p. 191) that the average distance of the faintest visible nebulæ is of the order of 500,000,000 light-years: "images of still fainter nebulæ, which cannot be distinguished from stars, are recorded on the photographic plates", but "it is improbable that any object has been recorded whose distance is double the average distance mentioned above".

These nebulæ have an average mass of about 10^{11} suns, and each shines with the light of about 10^{9} suns (p. 180). Within the limiting horizon at 500 million light-years' distance, about 100 million nebulæ are to be expected (p. 191), which means that nebulæ are scattered over the face of the sky at the rate of some 2,400 for every square degree. In the direction of the galactic poles, where the obscuring matter between us and outer space is least, some such number can actually be seen telescopically, so that in these directions we actually see more nebulæ than stars (p. 191). The nebulæ are to all appearances receding from us at immense speeds, those which are already farthest away running fastest; their speeds are about 101 miles per second for every million light-years of distance. If this relation between distance and speed were exact, nebulæ at the limiting distance of 500 million light-years would be receding at 50,500 miles a second, but nebulæ at a greater distance than about 250 million light-years do not emit enough light for their speeds to be deduced spectroscopically, so that the highest speeds so far definitely recorded are 24,500 and 26,000 miles a second—about a seventh of the velocity of light—from clusters in Boötes and Ursa Major respectively.

Such is the arresting feast of 'plums' which Dr. Hubble might have served up in sensational setting had he elected to play the sensation-monger. He has preferred, and we will all thank him, to give a straightforward record of patient and often laborious work, carried through with a skill, persistence and flair which often remind us of Faraday. He sees the whole exploration as "a case history of scientific research in a rather simple form" (p. 6), and this determines the style of his record.

A few pages of general astronomy, written to put the layman in a position to understand what follows, introduce us to novæ, Cepheid variables and the period-luminosity law for the latter. After this the record is chronological. In 1914 Slipher published a list of radial velocities of nebulæ, and in 1917 various photographic plates were found to carry records of a number of novæ which had appeared in the Andromeda nebula from 1885 on. The extreme faintness of the novæ and the large speeds of the nebulæ both suggested that the latter must be very remote, and almost certainly beyond the confines of the Galactic System. In 1924 the question was decisively settled by Hubble himself. He succeeded in resolving parts of a few of the nearest nebulæ into swarms of stars, and as these included a number of Cepheid variables, the distances of the nebulæ could at once be calculated from the periods of these variables. The distances proved to be nearly a million light-years, showing that the nebulæ were well outside the galaxy.

The next big advance was the classification of nebulæ into standard types, and the discovery, again by Hubble himself, that all the nebulæ of any one type exhibited the same surface-brightness. This suggested that all nebulæ of the same type were similar articles, and so gave a means of estimating the distances of all nebulæ whose type could be determined. This in turn made it possible to plot out the distribution of nebulæ in space.

Finally, we come to a discussion of the apparent recessions of the nebulæ, for which the author prefers the non-committal description "reddening of the light". The main labourer in this part of the field has been Milton Humason, using the remarkable Rayton lens of focal ratio f 0·6. The still more speedy f 0·35 lens designed by R. J. Bracey is not yet in use. Humason has measured the velocities of about 150 nebulæ and clusters of nebulæ, and their close agreement with the velocity-distance relation (101 miles a second for each million light-years of distance) is very remarkable, especially in the case of the clusters, where the superposed random motions of individual nebulæ average out.

So far the author has been an observer writing solely of observers and observations, but he is now compelled (a little regretfully ?) to admit the impossibility of keeping observation and theory in distinct compartments.

> "As we look out into space, we look back into time. The light left the twenty-first magnitude nebulæ perhaps 120 million years before it passed the twentieth magnitude nebulæ, and 250 million years before it reached the 18·5 magnitude nebulæ During these immense periods the nebulæ, if red shifts were velocity-shifts, would have receded to appreciably greater distances than those estimated from their apparent faintness. Thus the observed distribution would require corrections to reduce it to a 'simultaneous description'. Attempts to determine the corrections . . . force the research into the field of relativistic cosmology".

This leads to an all too brief discussion—only four pages—of cosmology, in which the author reaches the arresting conclusion that two schemes at most are consistent with the observed distribution of nebulæ in space. In one, the so-called "velocity-shifts" do not result from velocities at all, so that the observed reddening of the light must be the result of some "hitherto unrecognised principle whose implications are unknown". In the second, the universe is "very small". "In order to save the velocity-shifts, we would be forced to conclude that the universe is so small that we are now observing a large fraction of the whole." And this second alternative seems almost—but not quite—ruled out by the low density of matter in space.

Thus the book ends, as the author says, "on a note of uncertainty. And necessarily so. With increasing distance our knowledge fades, and fades rapidly. Eventually we reach the dim boundary—the utmost limits of our telescopes. There we measure shadows, and we search among ghostly errors of measurement for landmarks that are scarcely more substantial".

In this way, after conducting us to the absolute frontiers both of knowledge and of the astronomical universe, Dr. Hubble leaves us. We regretfully but gratefully take our farewell, with the hope that many years of health and vigour may be in store for him, to enable him to carry on his work with a yet larger telescope, and perchance to stretch the visible universe to many times its present dimensions. J. H. J.

Evolution of the Elephants

Proboscidea:
a Monograph of the Discovery, Evolution, Migration and Extinction of the Mastodonts and Elephants of the World. By Prof. Henry Fairfield Osborn. Edited by Mabel Rice Percy. Vol. 1: Moeritherioidea, Deinotherioidea, Mastodontoidea (Published on the J. Pierpont Morgan Fund by the Trustees of the American Museum of Natural History.) Pp. xl+802+13 plates. (New York: American Museum Press, 1936.) 5 dollars.

SINCE the discoveries of the late Dr. C. W. Andrews and Mr. H. J. L. Beadnell in Egypt at the beginning of this century, the origin and evolution of the elephants seem to have become clear. They began at the dawn of the Tertiary period in northern Africa as small amphibious pig-shaped hoofed mammals, with a nearly complete set of teeth but the second pair of incisors above and below growing large to become tusks and predominate over the others. In the course of ages, while the primitive elephants developed into larger and less amphibious animals with longer legs, the neck always remained short, so that the head and jaws had to lengthen to reach the ground. The bone of the lower jaw continually lengthened for this purpose, but that of the upper jaw did not do so, and the extension of the face was thus left entirely without hard parts. Throughout the middle portion of the Tertiary period, the long soft face was supported only by the rigid lower jaw. Then in the elephants of later Tertiary times the lower jaw began to shorten, until eventually it left the soft face hanging downwards as the familiar proboscis.

About thirty years ago, the late Prof. H. F. Osborn started to recount this fascinating story in detail. After that time he devoted much labour to the collection, study and description of the requisite fossils; and when he died in 1935 he had nearly completed an exhaustive volume on the subject, which has just been published by the American Museum of Natural History with the aid of the J. Pierpont Morgan fund. It is one of the most handsome contributions ever made to palæontology, beautifully printed and excellently illustrated.

At the outset, Prof. Osborn remarks that his selection of generic names may give "a shock to many zoologists", but he has decided to respect "soundly established usage and commonsense". His nomenclature can therefore be readily understood by those who are familiar with the classic writings on Proboscidea. The technical definitions of species, genera and higher groups are supplemented by numerous discussions of relationships; and there are useful synoptical tables of comparison, measurements, and geological and geographical distribution. Most important of all perhaps are the remarkable illustrations, which include photographic reproductions of nearly all the published figures of fossil proboscidean remains, besides numerous new figures that are often conveniently arranged in groups for comparison. To these are added maps showing the distribution of the various species, genera and families, and also striking restorations of the possible appearance of the extinct proboscideans when they were alive.

The small *Moeritherium*, of which the greater part of the skeleton has been found in the Upper Eocene and Lower Oligocene deposits of Egypt, is still the only known ancestral proboscidean in which the face has not yet begun to develop into a proboscis. Its skeleton seems to show that the animal was more adapted for an aquatic life than the hippopotamus, and it probably fed on succulent plants mainly under water. The many resemblances of *Moeritherium* to the aquatic mammals of the order Sirenia are thus very interesting, and there cannot be much doubt that common ancestors of the proboscideans and sirenians existed somewhere during the Cretaceous period. As neither *Moeritherium* nor any of its allies has hitherto been discovered outside Egypt, Africa still appears to be the region in which the search for these ancestors may be most hopefully made.

Contemporary with the latest species of *Moeritherium* in the Lower Oligocene of Egypt are two more advanced proboscideans, *Palæomastodon* and *Phiomia*, in which there is a long soft face supported by the elongated front of the lower jaw. As might be expected, the species of these genera are larger than those of *Moeritherium* and they seem to have lived in forests, hence the comparative scarcity of their fossil remains. Very curiously, it is difficult to regard them as the direct descendants of *Moeritherium* which flourished earlier in the same region, and Prof. Osborn considers that they represent the beginning of two distinct groups of mastodonts which are traceable in later Tertiary rocks of both the Old and New World.

A little later, in the Lower Miocene of Africa, Europe and Asia, *Deinotherium* suddenly appears. It ranges upwards to the Middle Pliocene in Europe and even to the Pleistocene in Africa, but it does not appear to have reached America. Although the species increase in size until the latest and largest attain the dimensions of the largest true elephants, they all keep comparatively small crushing teeth much like those of the primitive *Moeritherium*, and all have lost the upper tusks. As the crushing teeth are adapted for succulent food, and as the downwardly turned lower tusks might well be used to hold on to a bank, *Deinotherium* was long supposed to have been an aquatic animal; but Prof. Osborn has pointed out that the skeleton which has been discovered in recent years is as completely adapted for life on land as that of the ordinary elephants. It is therefore interesting to observe that many of the true mastodonts—the Rhynchorostrinæ of both the Old and New World—are now known to have had the same downwardly directed lower tusks.

The mastodonts ended everywhere in large animals with a short skull and lower jaw and a freely hanging proboscis, like the corresponding parts of a typical elephant. All their earlier representatives, however, had the long soft face resting on the bone of the elongated lower jaw, and they exhibited astonishing variety in this arrangement. The account of the variations occupies the greater part of Prof. Osborn's volume, and it suggests that there were several distinct lineages of primitive mastodonts evolving in nearly parallel directions. In some, such as *Platybelodon* from the Upper Miocene of Mongolia and an allied genus from the Pliocene of Nebraska, the lower tusks become large and flat, with a sharp edge, giving the front of the lower jaw the appearance of a shovel. These tusks are strengthened with a bundle of parallel cylindrical rods of dentine which occupy the ordinary position of the pulp cavity. In some mastodonts, such as *Serridentinus*, the lower tusks are comparatively small, while in others the long and slender lower jaw loses its tusks. Sometimes, as in *Megabelodon* from the Lower Pliocene of Nebraska, the slender tuskless lower jaw expands at the end into a 'spoonbill' where the roughened bone seems to have been covered with a hard dermal pad. In several lineages there is an ultimate tendency to the shortening of the lower jaw, but it is at present impossible to decide which became extinct and which led to the mastodonts with a completed proboscis.

The best known of the later mastodonts with an elephant-like proboscis is still the *Mastodon americanus*, to which Prof. Osborn devotes thirty well-illustrated pages. It occurs both in the preglacial Pleistocene formations and in many postglacial deposits in North America, and the molar teeth in the latest variety seem to differ from the earlier teeth in having sharper ridges. Teeth from southern Russia and China have been ascribed to the same species, but Prof. Osborn decided that these were wrongly named.

The next best known later mastodonts are those from the Pleistocene of South America, which are no longer referred to *Mastodon*, but to two or three distinct genera. Prof. Osborn thinks that the immediate ancestors of these proboscideans are recognizable in the Pliocene of North America, whence they must have migrated.

In the present volume, Prof. Osborn makes a great addition to our knowledge of the fossil Proboscidea, and provides an indispensable work of reference which will take its place among the classics of palæontology. Our only regret is that the printing of the volume began so long ago as 1924, and an appendix of nearly sixty pages, bringing the subject up to date, makes much of the text obsolete. The student must begin by reading the appendix, and then annotate the volume where the annotation has not already been done by footnotes or disturbing intercalations in black type. Even the reading is not easy, owing to the method of compilation, frequent repetition, and lack of literary style. A second volume, on the typical elephants, is due to be published next year, and we may express the hope that when it was unfortunately left by the author, the printing had not progressed too far to avoid some of the difficulties which the first volume presents.

THE different aspects of the task which faces a reviewer of scientific works may be grouped roughly under three heads. He should tell his readers in some detail the topics dealt with in the work under review; he should explain something of its scope; and he should attempt, with becoming modesty, to assess the value of the contribution made by the author to the spread or to the advancement of knowledge. Exigencies of space warrant some modification of this process when one is attempting an omnibus review. It is impossible, for example, to analyse separately the contents of twelve volumes, and the titles must be taken as indicating sufficiently clearly the topics dealt with.

The scope of the volumes may best be illustrated from a consideration of the audiences to whom such works may, or may not be expected to appeal. Taking the series before us as a whole, the volumes which comprise it are admirably fitted to assist students who are members of adult education classes of one or other of the many types in existence; they will assist workers in one branch of science to learn something of what is happening in regions unfamiliar to them; they are very suitable for a school library; and they will certainly prove useful aids to the inquiring layman who would know something of the trend of scientific thought in this restless universe of ours. The series is not likely to be of much use to the specialist or to the honours student seeking that conspectus of his subject which it is part of his business to make for himself. He may, however, find the volumes of very deep interest as illustrating the difficult art of presenting technical topics in elementary, and yet accurate, fashion.

Finally, have the authors succeeded in their task of limning an accurate and convincing picture of the state of existing knowledge of the topics with which they have concerned themselves? Obviously, an author who deals with sciences which have broken away from the simpler traditions of the nineteenth century and which employ a highly specialized jargon is, on a surface view, faced with a problem much more difficult than that which confronts an author dealing with a science qualitative in its outlook, and employing a not very highly specialized language. This is not to say that complex notions and arguments are the exclusive possession of him who employs a mathematical or logical notation. Far from it. Such a technique, once acquired, may become a potent weapon for saving thought and for grinding out results in purely mechanical fashion. Contrariwise, some most difficult and involved arguments may be developed without the aid of a single symbol. Still, when an argument is essentially mathematical, is fundamentally complex, and presents novel ideas, the task of the writer who would tell the story in simple language is not an enviable one.

The authors of the works under notice must be deemed to have succeeded in their task. The treatment is, in most instances, a little discursive in character, but that can scarcely be reckoned a fault, having regard to the audience to which the volumes may be supposed to appeal. They leave the reader with a clear picture of the subject-matter, and, while providing plenty of background, they do not in general overwhelm him with a mass of unessential detail.

This is not to assert that the volumes are completely free from error. On the contrary, there are, here and there, examples of unevenness of presentation and of obscurities of statement which may, occasionally, be positively misleading. The practice followed in some of the illustrations, of placing side by side examples of large-scale and of microscopic objects without the slightest indication of the magnification employed, is very much to be deprecated.

It is, perhaps, scarcely fair to single out for special mention one of a dozen good companions, but it is impossible to conclude this review without remarking on the admirable qualities of the volume on "Heredity and Variation".

The series is well produced and illustrated, and offers remarkably good fare at a very low cost.

Molecules and Morphogenesis

Order and Life
By Joseph Needham. (The Terry Lectures for 1935.) Pp. x+175. (Cambridge: At the University Press; New Haven, Conn.: Yale University Press, 1936.) 8*s*. 6*d*. net.

IN another context, Dr. Needham himself has likened the biochemist and the embryologist to the gangs drilling a tunnel from each end, and now just about to establish contact with one another. In fact, this contact may be said to have occurred, for knowledge of the chemical structure of protein molecules bids fair to throw light on the structure and properties of fibres (not excluding muscle); and the properties of liquid crystals can now be ascribed to certain living units.

Dr. Needham, whose researches entitle him to a place in the gangs of workers at both ends of the tunnel, has put forward a suggestion which may prove to be the turning point in the experimental attack on a problem of great topical interest and importance; namely, the morphogenetic fields, which he compares with the zone of influence which surrounds molecules possessed of the property of inducing orientation in neighbouring molecules. Cholesteric paracrystals have this property, and sterol-like substances are now known to be concerned in the morphogenetic activities of the 'organizer'.

The author's attitude to the philosophical position of biology is of great interest. Philosophers may find difficulty in accepting what they will probably believe to be Dr. Needham's attitude towards the Aristotelian distinction between matter and form. But Dr. Needham has done an inestimable service to 'natural philosophy' in emphasizing that the organizing relations in virtue of which organisms are more than the sums of their organs are legitimate objects for experimental analysis, and in showing that there is no haven for vitalism either in the indeterminacy principle of physical theory or in the mistaken notion that analysis of living organisms kills them and yields knowledge only of inorganic matter.

Dr. Needham pleads with logically irresistible eloquence for the recognition of the validity of a "biological level", and introduces to Western readers the often neglected writings of Marxist philosophers on this point. No doubt some biologists will discover that they have been thinking along similar lines. No biologist can afford not to read and ponder over this book.

G. R. DE BEER.

Mathematics for Technical Students

By Frederick G. W. Brown. Part 1 (First Year Course). Pp. x+215+xviii. 3*s.* Part 2 (Second Year Course). Pp. x+217–491+xxv. 3*s.* 6*d.* (London: Macmillan and Co., Ltd., 1936.)

IT is to be hoped that all teachers of mathematics in technical schools and evening institutes will have the opportunity of seeing these two books; for they provide a preliminary two-year course in mathematics which is exactly what is wanted at the present time.

After a revision of the simple operations of arithmetic, the student is introduced to the notation of algebra and made to see the value of this new weapon, until, finally, he should be able to solve arithmetical problems by means of a simple equation. This is followed by a short informal course of theoretical geometry; time spent on this section will be amply rewarded in the later stages of the course.

The concluding chapters of Part 1 deal with applications of previous work to the area of simple rectilinear figures and circles and to the volume of bodies of uniform cross-section. Some teachers will no doubt prefer to take this work earlier in the course—and there is much to be said for this view; teachers will find no difficulty in doing this.

Part 2 is necessarily more formal in character than Part 1. The first three chapters deal with logarithms and their many applications, plenty of useful exercises being provided; simple equations in two unknowns, fractions, harder fractions and quadratic equations complete the work in algebra. The remaining chapters deal with numerical trigonometry, harder mensuration and graphs, and applications of Simpson's rule. This last chapter could serve as a link in an introduction to the calculus for those students who proceed further with mathematics.

Typical sets of examination papers and useful mathematical tables are provided at the end of the book.

Teachers in evening schools have many problems to meet: the minimum number of students to form a class, intermittent attendance, the weariness of students who have done a day's work and the difficulty of an adequate supply of text-books; but if evening school students could handle and use these two volumes, examiners would soon find a considerable improvement in elementary mathematics.

L. C.

A Text-Book of Physical Chemistry

By Sylvanus J. Smith. Pp. xii+355. (London: Macmillan and Co., Ltd., 1936.) 5*s.* 6*d.*

THIS book is intended primarily to provide a course of physical chemistry for students preparing for the Higher School Certificate Examinations in science, also for candidates for university open scholarships, and for the First Examination for medical degrees. Such students will find the book very useful. In its 345 pages of text, the author more than covers the field of physical chemistry required by these examinations.

The subject matter is generally brought right up to date, but the older theories are also given their fair place. The section on the structure of the atomic nucleus, however, should now include a mention of the modern theory of its constitution from protons and neutrons. The excellent chapters on catalysis and colloids touch on many important industrial applications. A good selection of examination questions is given at the end of each chapter, with answers to the numerical examples in the appendix. The text is illustrated throughout with clear and helpful diagrams. Fig. 87 cannot correctly be described as the "Bunsen-Roscoe Actinometer" since it shows a mercury meniscus used in contact with chlorine gas.

The treatment is neither too elementary nor too advanced, and seems to be just the right standard required by the examinations for which the book is written

Graphical Solutions

By Prof. Charles O. Mackey. Pp. vii+130. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 12*s.* 6*d.* net.

GRAPHICAL and mechanical representations of practical equations are especially useful to the engineer, and this volume has been written to provide a systematic course in the subject. The first four chapters are devoted to stationary adjacent and sliding scales; network or intersection and alignment charts for equations in three variables and combinations of all these methods of solution. In the final chapter, the fitting of equations to experimental data is discussed. The treatment is quite elementary and involves only a working knowledge of logarithms, algebra and plane geometry, while a little calculus is required in the section on empirical equations. With the volume is provided a very clear reproduction of the logarithmic scales prepared by the late Prof. Lipka.

To those who have to deal with practical graphical computation, this book should prove very useful, instructive and interesting.

Sammlung chemischer und chemischtechnischer Vorträge

Begründet von F. B. Ahrens. Herausgegeben von Prof. Dr. R. Pummerer-Erlangen. Neue Folge Heft 33: Die Azoxyverbindungen: eine Monographie. Von Dr. Eugen Müller. Pp. 40. (Stuttgart: Ferdinand Enke, 1936.) 3.40 gold marks.

THE mode of representing the structure of the important class of the azoxy-compounds has recently undergone a change, based originally on chemical evidence provided by Angeli, and confirmed by the isolation of optically active substances by Marvel and E. Muller. The new formulation is a consequence also of the physical properties of the substances. The present monograph sets out clearly and accurately the grounds for the present representation of the structure of the azoxy-compounds, with full references to the literature. It is a useful contribution to the literature on the organic chemistry of nitrogen.

Science in Development*

By the Right Hon. Lord Rutherford, O.M., F.R.S.

IN surveying the great tide of advance in the physical sciences during the past forty years, it is not always recognized how much the progress of discovery has been influenced, and indeed in many cases controlled, by the improvement of laboratory technique and by the development of new instruments and methods of measurement.

To appreciate the rapid changes which have occurred, it is probably simplest to contrast the laboratory equipment of to-day with that available at some well-defined epoch in the past. I choose for this purpose the year 1895, that turning point in the history of physics, which saw the discovery of X-rays, to be followed in quick succession by the discoveries of radioactivity and of the electron. This choice of year seems to me convenient as it marks a natural dividing line between the older and the newer physics.

First of all, I should like to refer to the great advantages to research in general that have followed from the invention of an efficient form of lead accumulator. Before the commercial manufacture of the accumulator, the experimenter had to rely on primary batteries for the supply of electric current in his investigations. The Daniell cell or corresponding battery was used for small currents—as, for example, in comparing resistances by the Wheatstone bridge. For the supply of currents of the order of an ampere or more, Grove's cells were often used, but these had only a working life of a few hours and had to be freshly prepared each day. When I first began some investigations on the magnetic properties of iron in 1893 at Canterbury College, Christchurch, New Zealand, I found it necessary to prepare each morning a battery of about a dozen Grove cells. This involved the cleaning and amalgamation of the zinc plates and adding the necessary acids. Fortunately, large platinum plates for the electrodes were available. I found this battery of low internal resistance a very convenient means of obtaining substantial and steady currents, but after several hours' work the battery showed obvious signs of exhaustion and accurate work with it was impossible.

In order to illustrate the provision for research forty years ago, I shall take as an example the Cavendish Laboratory, which was directed by Sir J. J. Thomson, who was then on the verge of beginning his famous experiments on the electrical conductivity in gases produced by X-rays and his investigations of the nature of the cathode rays. The equipment of the Cavendish Laboratory both for teaching and research was probably typical of the better European physical laboratories of that time. Largely due to the labours of the late Sir Richard Glazebrook and of Sir William Napier Shaw, a well-organized system of laboratory instruction had been arranged for students, and this was extended and elaborated through the years by that genius in the design of laboratory apparatus for teaching purposes, Dr. G. F. C. Searle.

While the provision for teaching and research was in general excellent in the older sciences of optics, heat, sound and properties of matter, in contrast with to-day the amount of electrical apparatus, particularly on the measuring side, was sparse and in some cases almost non-existent. Apart from reflecting galvanometers of the moving magnet and moving coil types and a tangent galvanometer, there was no portable instrument for measuring current except one very crude form of ammeter. The only portable method of measuring voltage was a rather ponderous Cardew voltmeter of the hot wire type, which was of very limited utility and accuracy. It was not until a few years later that those admirable instruments for measuring current and voltage designed by the late Mr. Edward Weston of the United States came into laboratory use. To-day, hundreds of measuring instruments of this or similar types are required in electrical research, and indeed a single experimenter may feel himself hardly used if a dozen of these instruments are not available, with appropriate wire rheostats to control the voltages and current.

Apparatus for work in electrostatics was more plentiful, including a number of types of quadrant electrometer, which, however, were usually both unreliable and capricious instruments. The quadrants were large and the needle unnecessarily heavy. The moving system was often supported by a silk fibre and the position of the needle controlled by a small magnet attached to it. A platinum wire was attached to the bottom of the needle and dipped in strong sulphuric acid, which formed the inner coating of a small glass condenser. In order to obtain a reasonable sensitivity, the needle and condenser required to be charged to a fairly high potential. This was done by charging the jar with a spark or two from an electrophorus or from a charged Leyden jar. Unless very special precautions were taken with the insulation, the charge on the condenser leaked away rapidly and the sensitivity of the electrometer varied markedly from hour to hour, while the zero of the needle was very unsteady. Under these conditions, it was difficult to make observations over any but a short period with any accuracy. Lord Kelvin, the pioneer in the construction of quadrant electrometers, had designed a more elaborate and more serviceable instrument in which the potential of the charge given to the needle could be brought to a definite value by the use of an attracted disk electrometer incorporated with the instrument. One of these electrometers, which was available in the Laboratory, was made after great effort to work satisfactorily by Prof. J. S. Townsend, and was used by him in his well-known researches on the electrification of gases and on the properties of ions in gases. This, I believe, was the first time this instrument, which was of moderate sensitivity, had been used in systematic researches of importance.

---

* From the twelfth annual Norman Lockyer Lecture of the British Science Guild, delivered on November 12.

A great advance was made about 1900 when Dozalek designed a quadrant electrometer with a fine quartz suspension and a very light needle, which gave a good sensitivity when the needle was charged to the comparatively low potential of a few hundred volts.

In place of the quadrant electrometer, the tilted electroscope designed by C. T. R. Wilson in 1903 was often used. This had a low capacity and a voltage sensitivity comparable with an electrometer. Recently a very sensitive form of this instrument has been designed by H. Carmichael and used for experiments on the bursts of ionization produced by the cosmic rays. After the Great War, still more sensitive electrometers were designed; for example, a modified quadrant by Compton, and a binant electrometer of high sensitivity by Hofmann, while a robust and portable type of string electrometer of good sensitivity designed by Lindemann has proved very serviceable in many directions. At this stage, I must not omit to mention the extraordinary utility of a modified form of the gold leaf electroscope for measurement of ionization, particularly in the study of the radioactive bodies. This instrument, which had been used for detecting charge for a century or more, was developed into an accurate measuring instrument largely due to the modifications introduced by C. T. R. Wilson. In course of time the electroscope displaced the quadrant electrometer for measuring the periods of decay of radioactive bodies and for a study of the α-, β- and γ-rays.

The changes in forms of apparatus so far mentioned did not involve any essential new principle, but were rather the result of improvement in design to increase their sensitivity and reliability, and to adapt the form of the instrument to meet the needs of investigators. To this period, however belongs the development of an instrument which to my mind is the most original and wonderful in scientific history—I refer to the 'cloud' or 'expansion' chamber of C. T. R. Wilson. I had the good fortune to be present in 1895 in the Cavendish Laboratory when Wilson was examining the formation of water drops in damp dust-free air by sudden adiabatic expansion of the gas. When X-rays were discovered, Wilson at once showed that the ions produced by the X-rays in their passage through the gas acted as nuclei for the condensation of water upon them under certain conditions of supersaturation. A cloud of visible water drops was formed and in a sense each ion was rendered visible by the water drop formed round it.

The next important advance was made in 1912, when Wilson devised the modern type of expansion chamber and showed that the tracks of individual α-particles and fast electrons are rendered visible by the trail of water drops formed on the ions liberated by the passage of these flying particles through the gas. It was a wonderful advance to be able to see, so to speak, the details of the adventures of these particles in their flight through the gas. Anyone with imagination who has seen the beautiful stereoscopic photographs of the trails of swift α-particles, protons or electrons, cannot but marvel at the perfection of detail with which their short but strenuous lives are recorded. The cloud chamber has proved an invaluable aid to research in many directions and has become all-important in recent work on artificial transmutation. This instrument provides in a sense a final court of appeal in which the experimenter may place his trust. I cannot imagine anyone with the most vivid scientific imagination who could have predicted the possibility of an instrument endowed with such unique powers and potentialities.

HIGH VACUA

Of all changes in laboratory apparatus and technique in the period under review, none has been more revolutionary in type or of more importance to the progress of science and industry in many directions than the improvements in methods of rapid production of high vacua. Vacuum research has a long history and has persistently engaged the attention of scientific men from the year 1643, when Torricelli, the assistant of Galileo, made the first mercury barometer. The first mechanical air pump was devised by von Guericke in 1650. It was a simple type of suction pump with a well-fitting plunger and automatic leather valves, and was probably able to reduce the pressure of air in a sealed container to between 1/100 and 1/1,000 of an atmosphere.

While mechanical pumps were improved, no great advance in principle or practice of producing high vacua took place for nearly two hundred years. To be sure, many investigations were made, for example, by Hawksbee, to investigate the beautiful glow discharges observed when an electrical spark passed through a vessel containing gas at very low pressure. While mechanical pumps were often used for special purposes, the Torricelli principle was more popular and effective in producing a good vacuum.

The most important stage in the subsequent advance was the invention in 1855 of the mercury pump proper by Geissler, who used it for exhausting discharge tubes in order to illustrate the striking luminous effects which arise when the electric discharge from an induction coil is passed through the low-pressure gas contained in the tube. Such Geissler tubes were long used for illustrations in lectures, and replicas of them may still be seen to-day. The invention of the mercury pump gave the possibility of producing a really good vacuum by long-continued pumping. The advantage over the mechanical pump was due primarily to the elimination of the mechanical valve and the dead space. The mercury pump was used by Hittorf for studying the marked changes in the appearance of the electric discharge as the pressure of gas was decreased to the lowest value obtainable. He observed the conditions of production of the now well-known cathode rays and was, I think, the first experimenter to appreciate that, in order to maintain a permanently good vacuum in a sealed tube, it was necessary to 'degas' the walls of the tube and electrodes by frequent heating and long-continued bombardment by the electric discharge. In this way he produced, for the first time, a tube with so good a vacuum that an induction coil failed to produce any visible discharge through the highly rarefied gas.

The work of Hittorf was extended and improved upon by Sir William Crookes, who used a modified form of mercury pump invented by Sprengel in 1865, which could readily be made automatic in action. A number of modifications of Geissler's original pump were made from time to time, and of these the pump devised by Toepler in 1862 came into general use towards the end of the nineteenth century. When I first came to the Cavendish Laboratory in 1895, modified forms of Toepler pump, made by that skilled glassblower Mr. Everett, were in general use. One of these pumps was used by Sir J. J. Thomson in his famous experiments which proved the nature of the cathode rays. In those days, it was usual to employ a one- or two-cylinder Fleuss pump for preliminary pumping of the vessel to a pressure below 1 mm. This pump was a greatly improved form of the original mechanical air pump of von Guericke. The moving piston and working parts were covered with a layer of oil. The small quantity of air entrapped by the upward motion of the piston was forced with the oil through a spring valve. By these modifications, the efficiency of the pump in reaching a low pressure was much increased. Under good conditions a vacuum as low as 1/50 mm. could be obtained. It should be borne in mind that the production of a good cathode ray vacuum in a discharge tube in the old days was a lengthy and laborious process with the slow-acting Toepler or Sprengel pumps. Several hours pumping was required to produce a good vacuum by these methods, while to-day, with our fast diffusion pumps, a similar result can be obtained in a few minutes or even seconds. It is of interest to record that the X-ray tubes first used for radiographic purposes were all painfully exhausted by one of these early forms of mercury pump.

From the point of view of ease and simplicity in maintaining a good vacuum, the discovery of Sir James Dewar in 1904 that specially prepared charcoal was a strong absorbent of gases at low temperature has proved of great importance to science. The tube to be exhausted was connected with a side tube containing charcoal. After preliminary exhaustion with a mechanical air pump, the charcoal was immersed in liquid air, when the residual gases in the tube were rapidly absorbed by the charcoal and a high vacuum produced which could be maintained for hours. This method of producing a controllable degree of vacuum was widely used for many years in our laboratories. For example, this method was employed by Sir J. J. Thomson in his well-known experiments on the positive rays, and on account of its simplicity is still used by Aston in his investigations with the mass-spectrograph.

The last thirty years have seen great changes in our methods of rapid production of high vacua, and many new and ingenious types of fast pumps have been invented. This rapid development has been in large measure due to the remarkable powers of invention shown by Dr. Gaede, who has designed a whole series of pumps of great scientific and technical interest.

The first glass diffusion pump employing a stream of mercury vapour was described by him in 1915, and has been followed by a succession of designs of increasing efficiency. This pump, which has the advantage of containing no movable parts, can be constructed either of glass or metal, and a great variety of forms have been used, particularly in the case of small glass pumps for ordinary laboratory use. Improvements in the design of the all-metal diffusion pump to ensure higher pumping speeds were early made by Langmuir in the United States and by Kaye in Great Britain. Although there are great varieties of these pumps both as regards size, form and construction, they all depend on the same general principle. The gas to be removed diffuses through a suitable aperture into a stream of hot mercury vapour which carries the gas away with it, the mercury vapour being afterwards condensed and the gas removed by a backing pump. The speed of exhaustion of these pumps is astoundingly fast, and theoretically there is no limit to the degree of vacuum that can be obtained. In general, a single-stage pump requires the pressure to be reduced by a fore pump from 1/10 to 1/100 mm. before the pump comes into action. Gaede has designed a 3-stage all-steel pump which begins to operate at a pressure of 20 mm. and has a high speed of exhaustion.

In the mercury diffusion pumps it is usual to employ a liquid air trap to prevent the back diffusion of the mercury vapour into the vessel to be exhausted. This is a disadvantage both from the point of view of economics and of efficiency in pumping, and has been got over by replacing mercury by a special oil which has a negligibly small vapour pressure at ordinary temperatures, so that liquid air is dispensed with. The first oil diffusion pump was constructed in Great Britain by Mr. C. R. Burch of the Metropolitan-Vickers Research Laboratory, using special oil obtained by molecular distillation. These pumps are very efficient and are very widely used, particularly for large sizes of pump where great volumes of gas have to be rapidly removed.

The invention and development of the diffusion pump has given to science a new and extraordinarily effective instrument for the rapid attainment of the highest degree of vacuum. Not only has its use greatly simplified investigations in very high vacua, but also it has made possible many new technical developments. With the aid of these fast pumps, we can maintain large vessels at such a low pressure, even when gases are pouring in through a small opening, that voltages of the order of 1 million volts can be applied without the passage of a discharge. This has made it possible to obtain streams of very fast particles, for example, protons and deuterons, which have proved so effective in studying the transmutation of the elements.

I have already mentioned incidentally some of the more fundamental discoveries that have resulted from a study of the electric discharge through rarefied gases; for example, the production and nature of the cathode rays, the discovery of the X-rays and the development of new methods of analysis of the charged atoms and molecules produced in the discharge tube. The resolving power of this method of chemical analysis has been so improved by Aston that it has been found possible not only to show the isotopic constitution of many of the ordinary elements, but also to determine the relative masses of the atoms with high precision. The use of high vacua led to the investigation by O. W. Richardson of the copious emission of electrons from incandescent bodies—a discovery from which has originated many important industrial applications. In general, the study of processes in very high vacua has added much to our knowledge in many directions. The pioneer work of Langmuir on chemical reactions at very low pressures and on adsorption phenomena has opened a new and important field of inquiry which is still being developed. Much light has been thrown on the formation of monomolecular films on surfaces and their importance in catalytic reactions, and in general on the nature of chemical and physical forces which come into play. The use of molecular rays by Stern and Gerlach was only made possible by high vacuum technique.

I have so far only spoken of methods of producing high vacua, but in the course of this development not only have reliable methods been devised for measurements *in situ* of the residual pressure of the gas, but also great advances have been made in industrial laboratories in the technique of making metal seals with glass, for example, copper, steel and tungsten. This has made possible the production on a commercial scale of robust tubes of combined glass and metal such as are used for high-power rectifiers and oscillators. In addition, the industrial laboratories have been responsible for many improvements in technique. Many new kinds of glass have been produced and methods devised for graded glass joints, such as pyrex to soft glass and silica to pyrex. The high-frequency eddy current heater for degassing metal parts *in situ* has proved of great value, while the technique for degassing tubes, whether by heat or the electrical discharge or both together, has been highly developed. Special machines have been devised for rapid exhaustion and sealing of glass bulbs. The production of low vapour pressure oils and greases has made possible the efficient and economical oil diffusion pump and improved methods for air-tight joints.

In the development of high vacua, the mutual reaction between science and industry is illustrated in a striking way. The pioneer work of the physicist led to the development of methods of producing high vacua and to many new discoveries of the properties of matter in rarefied gases. These new methods have been applied to industry in a great variety of ways, and in turn have provided the physicist not only with improved forms of apparatus but also with many new technical devices which have made possible still further progress in pure physics. For example, the production on a commercial scale of efficient amplifiers, thyratrons and rectifiers, has provided the physicist with new and powerful weapons for extending his investigations in many directions. These developments have made possible not only the production of streams of swift particles for work on transmutation, but also methods of automatic counting of the swift particles which result from the transformations. These new counting methods owe much to the ingenuity of Dr. Wynn-Williams. On account of these great improvements in technique and methods, progress in our knowledge has been so accelerated in the last few years that it is not easy for the investigator to keep in close touch with the rapidity of advance of new knowledge.

There have also followed great improvements in the efficient production of X-rays, and I must not omit to mention the development by Coolidge of the hot cathode, highly exhausted X-ray tube, known by his name, which has proved so valuable both for scientific and medical purposes. I could give many other illustrations of the beneficial effects of this close mutual relation between the workers in our university and technical laboratories —a happy relation which cannot fail to be of good augury for the future.

J. L. Macadam: Father of Modern Road-Making

By Dr. R. Quarendon

THE centenary of the death of J. L. Macadam comes at a particularly fitting time, because the history of the roads is passing through a stage very similar to that which marked the years of Macadam's greatest activity. Then, as now, transport was being handicapped by the lack of modern highways, and the march of progress hindered by out-of-date conditions.

The roads were in many cases little better than they had been in the Middle Ages. Two hundred years of neglect, ignorance and prejudice had left them in an appalling state of disrepair. Journeys which now take hours lasted for days or even weeks, and were undertaken only after anxious consideration.

Parliament had done its best to suppress the wheeled vehicle, or to regulate it as a nuisance. Act after Act was passed restricting the loads to be carried, the number of horses per wagon, and the size and shape of the wheels. Excepting the 22,000 miles of turnpikes, the repair of the roads was in the hands of the parishes, who were empowered to conscript labour—known as 'statute labour'—whose services were given with the greatest unwillingness. The 1,100 turnpike trusts were run in many cases by ignorant and incompetent men who took the revenues but spent little on repairs.

Lacking engineering training, Macadam seems to have developed his method from first principles. It was at thirty years of age, after having gained a fortune as an agent for the sale of prizes in the American War of Independence, that he returned to Scotland to begin his experiments. As magistrate, deputy lieutenant and road trustee for Ayrshire, he was able to give considerable time to this work. His efforts met with the greatest opposition, in spite of the fact that it was his own money which was being spent on the investigation. The Scots people did not want a hard metalled road. They preferred to drive their cattle and geese to market over the soft earth roads which then prevailed.

For many years, Macadam was unable to test his ideas on a suitable scale. In 1798 he was appointed agent for revictualling the Navy in the western ports, and his duties afforded little time for road research. It was not until 1815, when he became surveyor-general of the Bristol roads, that the opportunity for which he had been waiting arrived.

The usual method of making a road in those days was to dig earth from ditches cut along the side, and to pile it in the middle, in the pious hope that the traffic would beat it into a hard surface. Sometimes gravel was thrown on top, but in wet weather the earth and gravel soon became churned into a pebbly mud. Although he was a pioneer of his day, all Macadam really did was to provide a durable, properly drained bed of road metal. He excavated the earth to a depth of 6–10 inches, according to the nature of the subsoil, and filled in the trench with layers of stone broken to one-inch cubes. The traffic was allowed to consolidate the broken stone until it knit together to form a hard smooth surface impervious to water.

Macadam's methods differed from those of his contemporary Telford in two ways. He used no large blocks of stone as a foundation, because he maintained that a soft, elastic base which 'gave' a little would withstand heavy traffic much better. Neither would he have gravel or similar binding material in the surface layer, as Telford recommended.

Many roads which are nowadays described as 'macadam' are not macadam at all, according to the strict letter of the method described by the inventor of the process. They are laid with small material mixed with the larger pieces to act as a binder, a thing which Macadam absolutely forbade. His was a counsel of perfection, however, because unless the stones have the correct shape they will not bed down without admixture to form the regular mosaic characteristic of the true macadam.

Macadam's energy and persistence gradually bore fruit. The enormous improvement of the roads under his jurisdiction became generally known, and in 1823 he described his methods in evidence before a committee of the House of Commons. As a result, macadam replaced the granite causeways in many of London's important streets, in spite of the dismal predictions of people who opposed the change. Southey wrote that "macadamising the streets of London is likely to prove quackadamising", but that opinion was probably due more to his admiration for Telford than to any critical examination of the available facts.

Before recognition came to him, Macadam spent £5,000 out of his own pocket in developing his method, and travelled 30,000 miles to help officials and others who asked for his advice. The greatly increased speed of the coaches gives a striking proof of the soundness of his ideas, which made English roads the best in the world. Whereas the journey from London to Edinburgh used to take 14–16 days, the time had fallen by 1830 to 40 hours—a remarkable improvement. In recognition of his services, Parliament voted him £10,000, which he accepted, and he was offered a knighthood, which he declined. His son accepted the honour in his stead.

Macadam described his researches in his memoir: "A Practical Essay on the Scientific Repair and Preservation of Public Roads", published in 1819. Other works on the same subject appeared from his pen. He died on November 26, 1836, in his eighty-first year at Moffat, near Telford's birthplace, on one of his frequent visits to the scenes of his boyhood.

Although many of Macadam's roads remain, they can no longer compete with the concrete 'speedways' of the modern era. They belong to a quieter age, when the horse jogged leisurely along the country lanes, and the passengers had time to notice the honeysuckle in the hedgerows. Yet they were our roads for more than a century, and it will be many years before the man who made them is forgotten.

Obituary

Prof. W. A. Parks, F.R.S.

The death occurred in Toronto, on October 3, of Prof. W. A. Parks, professor of geology in the University of Toronto. William Arthur Parks was born in Hamilton, Ontario, in 1868, and educated in Bowmanville High School and the University of Toronto. With his university he was to be associated for the rest of his life, and his career is a long list of ascending responsibilities. He graduated B.A. in 1892, became a 'fellow of geology' in the following year, and was in turn instructor, lecturer and, in 1905, associate professor. In 1913 he was appointed director of the newly constituted Royal Ontario Museum of Palæontology, an institution which has greatly developed under his guidance. From 1916 until 1922, Dr. Parks was professor of palæontology and in the latter year he was promoted to the full chair of geology.

With his large department and his museum ever increasing in importance, Prof. Parks was fully occupied, yet he found time to conduct expeditions in northern Ontario and to undertake research in various directions. He was particularly interested in American Stromatoporoidea and also published a series of papers on the geology and palæontology of the Toronto district. He was also interested in, and published a comprehensive account of, the building and ornamental stones of Canada.

In his later years, attracted by the rich material in his museum, Prof. Parks turned to vertebrate palæontology and described many new genera and species of highly interesting dinosaurs. Despite these numerous activities he found time for service on outside bodies. He was president of Section C (Geology) of the British Association at Southampton in 1925, president of the Royal Society of Canada, 1925–26, president of the Palæontological Society of America, 1926–27, and president of the Royal Canadian Institute, 1928–29. His talents were recognized in Great Britain by his election to the Royal Society in 1934.

For the last few years, Prof. Parks had patiently borne much serious illness, but his interest in his science and in his newly and greatly extended museum was not diminished. His death is a great loss to Canadian geology, and the sympathy of all who knew his pleasant and kindly personality will go out to his widow and his son. W. E. S.

Mr. D. A. Jones

MR. DANIEL ANGELL JONES, formerly secretary and afterwards president of the British Bryological Society, who died at Bristol on October 6 in his seventy-sixth year, has long been a familiar figure among Welsh botanists. Whilst he was a schoolmaster at Harlech his assistance was often invoked by botanists interested in the flora of North Wales, especially of Merionethshire and Carnarvonshire. His keen eye and wonderful memory of detail, locality and habitat were well known to phanerogamic botanists, and in the detection of bryophytes and lichens he was unrivalled.

During the present century, the story of Mr. Jones's life is largely linked up with that of the British Bryological Society. In 1895, a number of bryological enthusiasts formed the Moss Exchange Club. The main purpose was the exchange of specimens, but supplementary to this there was a desire to extend the knowledge of the distribution of bryophytes in Great Britain, as nothing in regard to this had been published since the issue of the second edition of the London Catalogue of British Mosses in 1881. In 1907, Mr. Jones took charge as secretary of the beginner's section (Section II) and continued that work until 1922, when both sections became merged as the British Bryological Society. He became secretary of this and continued as such until the early part of this year, when he felt compelled to resign on account of ill-health. The knowledge of the vice-comital distribution of bryophytes increased rapidly, and this increase was greatly contributed to by Mr. Jones. The "Census Catalogues of British Hepatics" (1905) and of "Mosses" (1907) were followed by a second edition for "Hepatics" in 1913 and a third in 1926, and a second edition for "Mosses" in 1930.

During the Great War, Mr. Jones was a Government lecturer on agriculture in connexion with University College, Aberystwyth, for which the University of Wales bestowed on him the degree of M.Sc. in 1918. In 1925, he was elected an associate of the Linnean Society, of which he had previously been a fellow (1897–1912). He became vice-president of the British Bryological Society in 1933 and president in 1935.

Jones was born in Liverpool on July 14, 1861, was a schoolmaster at Machynlleth for about six years, then at Harlech until he retired in 1924. After ten months spent in the study of bryophytes and lichens on the Continent, chiefly on the Riviera, he lived four years at Cheltenham, and the last five years of his life were spent at Bristol. His sense of humour, good fellowship and almost uncanny power of detecting rare or strange plants, rendered his presence amongst bryologists or lichenologists delightful and stimulating. W. W.

Mr. Marius Maxwell

BY the untimely death at the age of forty-eight years of Marius Maxwell, which occurred on November 2 at Nice in an accident to an aeroplane which he was piloting, the British Museum (Natural History) and those interested in the study of natural history have lost a keen supporter.

Maxwell had lived a most adventurous life and the manner of his death will come as no surprise to those who knew him best. He was a very generous donor to the Natural History Museum, and many of the specimens which he collected in his early days in Java and northern India have found a permanent home in the National Collection. Chief amongst these may be mentioned the skull of the record Javan rhinoceros (*Rhinoceros sondaicus*) which carries a horn of 10¾ in., and two skulls of the pygmy hog (*Porcula salvanius*) from Bhutan. Amongst his East African donations premier place must be given to the mounted head of a magnificent bull elephant which carries exceptionally long and slender tusks.

In 1911 Maxwell first visited Kenya Colony on a hunting trip between Nakuru and Lake Baringo, when the vast accumulation of game which he found in that country so impressed him that he determined to return later on a photographic expedition. The opportunity to re-visit East Africa did not come for another ten years, when in 1921 he conducted an expedition to the Masai Province and took some wonderful photographs of elephants and giraffes. One of the elephant photographs shows an old bull standing in the attitude of alarm with its ears widely spread; this photograph was taken at a range of 8 yards. It was there that he secured the amazing series of photographs of three elephants sauntering in a forest clearing, when he walked out into full view of the animals and proceeded to take about a dozen snapshots quite at close quarters. The giraffe photographs were some of the first photographs of galloping giraffe to be taken from a pursuing car, and Mr. Maxwell estimated the speed of these animals, when fully extended, as 28–32 miles an hour.

After a short trip to India on business, Maxwell returned to Mombasa in the spring of 1922 and went on another photographic expedition, first to Lake Natron and around the Tanganyika border in the south, and secondly up in the Northern Frontier Province along the Northern Guaso Nyiro. In the latter locality he obtained some excellent photographs of buffalo, elephant and hippopotamus. One close-up of a buffalo is especially awe-inspiring, as it shows the animal debating in its mind whether to charge or not. The elephant photographs taken in the region of the Lorian Swamp and at Abbas Wen are some of the most remarkable records ever made of these animals; this is especially true of the group of advancing elephants which forms the frontispiece of Maxwell's monumental work entitled "Stalking Big Game with a Camera", published in 1924 by the Medici Society. This volume is very handsomely illustrated by a large number of photogravure reproductions of Maxwell's photographs, and will remain for all time a standard work on the subject of East African big game. The volume contains an introduction by Sir Sidney Harmer, and in addition to the chapters on elephants, giraffes, rhinoceroses, buffaloes and hippopotamuses, also has an interesting appendix on the ancestry of the African elephant, and the relationship of primitive elephants to primitive man. The volume concludes with a chapter on some of Maxwell's experiences in hunting elephants in India. This *édition de luxe* was followed a year later by a somewhat smaller and cheaper volume containing the same text and illustrations.

Always seeking after new experiences, in 1925 Marius Maxwell visited the Birunga Mountains north-east of Lake Kivu, in the Eastern Belgian Congo, to study and photograph the Eastern gorilla. He was accompanied by Mr. J. H. Barnes, the well-known white hunter, who had been with him on his two previous trips in Kenya Colony. Although not having very great luck in photographing the gorilla itself, he took some very interesting photographs of the gorilla forests, of their sleeping platforms and of gorilla shelters. Further, he secured a unique snapshot of a female gorilla carrying on her back a young one; this, I think, is the only pictorial record of this method of juvenile transport in this species.

Maxwell had graduated at Zurich and took up the profession of engineering, specializing in the machinery concerned with the manufacture of cane-sugar, and he erected many sugar factories in India. Latterly, he had interested himself in coffee-farming, and lived on a large estate at Thika Bridge in Kenya Colony. He married in 1929 Miss Winifred Ramsay.

GUY DOLLMAN.

Lieut.-Colonel Robert Knowles, C.I.E.

It is no exaggeration to say that tropical medicine has sustained a grievous loss through the early decease, on August 3 at fifty-two years of age, of Robert Knowles after a brave struggle with prolonged ill-health, aggravated by exceptionally hard work which a keen sense of duty would not allow him to relax.

After completing his medical studies at Cambridge and St. Mary's Hospital, Knowles took the first place at his entrance into the Indian Medical Service in 1908 in its palmiest days, and, after some years in military employ, obtained his first opportunities for research under favourable conditions at the Kasauli Institute. Here he began a happy and successful collaboration with his friend, H. W. Acton, and they made important contributions on the subject of snake venoms. Here he also commenced his fruitful work on protozoology in connexion with the halteridium. After the interruption caused by the Great War, when he was severely wounded in Mesopotamia, he took charge of the recently founded Pasteur Research Institute in the beautiful hill station of Assam at Shillong, where his energies and organizing ability found ample scope, and where he commenced his important investigations on kala-azar.

When Sir Leonard Rogers had to return home a few months before he had completed the organization of the Calcutta School of Tropical Medicine, he asked that Knowles should succeed him, and once more he was an outstanding success, and soon became professor of protozoology, with his friend Acton as professor of bacteriology, and during the next sixteen years his work there can only be described as most remarkable. His most outstanding discovery was the demonstration, with the aid of L. E. Napier and R. O. A. Smith, that the sand-fly, *Phlebotomus argentipes*, was the long sought-for carrier of the infection of kala-azar. Later he did valuable work on a parasite of monkey malaria called *Plasmodium knowlesi* after him.

Knowles was equally distinguished for his medico-literary work, and was a clear and prolific writer, his work on medical protozoology being of exceptional merit, and those with Acton on the dysenteries of India, and with S. White on malarial literature in India were of great value. First as assistant editor with Sir John Megaw, and later as editor of the *Indian Medical Gazette*, he raised its standard and contributed invaluable summaries of the advances during each year, at the compilation of which he was a master.

Knowles's short, thickset figure, abounding in energy and enthusiasm, combined with the unselfish and cheerful manner in which he always found time to help any of his colleagues, British or Indian, makes his early loss quite irreparable to his innumerable friends.

Dr. W. F. Sheppard

Dr. W. F. Sheppard, late assistant secretary, Board of Education, died on October 12 in his seventy-third year. He went up to Trinity College, Cambridge, was Senior Wrangler in 1884 (Parts I and II) and was placed in Division I of Part III in 1885. He was elected a fellow of Trinity in 1887. For these particulars we are indebted to the obituary in *The Times*.

The name of Sheppard is well known to mathematical statisticians. In 1898 he published in the *Phil. Trans.* (A, **192**, 101) a memoir "On the Application of the Theory of Error to Cases of Normal Distribution and Normal Correlation", in which the theory is developed by very elegant geometrical methods. It was in this memoir that he gave the noteworthy theorem, that if a fourfold table is formed from a normal correlation table by division at the medians, the coefficient of correlation r is given by

$$r = \cos\left(1 - \frac{2n}{N}\right)\pi,$$

where n is the frequency in either of the positive quadrants.

Much of Dr. Sheppard's work, in the *Proceedings of the London Mathematical Society* and elsewhere, was concerned with the method of finite differences and its applications. By this method he derived the well-known 'Sheppard's corrections' for determining more accurately the moments of a grouped frequency distribution (*Proc. Math. Soc.*, **29**, and *Biometrika*, 5, 1907). For these, and for his tables of the ordinates and integral of the normal curve given in "Tables for Statisticians", his name is known to almost every student of the subject. But his work really covered a considerable range, and we may note, amongst others, papers "On the Statistical Rejection of Extreme Variations" (*Proc. Math. Soc.*, **31**), "On the Use of Auxiliary Curves in Statistics of Continuous Variation" (*J. Stat. Soc.*, **63**, 1900) and on "Graduation by Reduction of Mean Square Error" (*J. Inst. Actuaries*, **48**). Of recent years he does not seem to have written so much on statistical matters, but some time since he made a return to pure mathematics and published through the Oxford Press a small book, "From Determinant to Tensor" (1923).

G. UDNY YULE.

News and Views

Nobel Prize for Chemistry: Prof. P. Debye

THE award of the Nobel Prize for chemistry for 1936 to Prof. P. Debye will give great pleasure to his friends everywhere. Debye's contributions to science have been many, and have covered a wide range of subjects, but they all have certain features characteristic of the man who made them. He combines, in a remarkable way, ability in mathematical analysis with a sturdy sense of physical realities, so that he is able to make bold approximations without invalidating the formulæ at which he arrives. His early training as an engineer, followed by his training in theoretical physics under Sommerfeld, must have contributed to this striking combination of qualities. They have been shown equally by his all-important work on specific heats, on dipole moments in gases, and on the theory of strong electrolytes. He has made notable contributions to X-ray analysis, in particular the 'powder-method', the theory of scattering of X-rays by molecules, and the effect of temperature on X-ray diffraction. He is a delightful and inspiring lecturer. All who know him have the double pleasure of seeing the award so appropriately bestowed, and of being able to congratulate a kindly and delightful friend. Prof. Debye received the Royal Society's Rumford Medal in 1930, and in 1933 was elected a foreign member of the Society.

Nobel Prize for Physics: Prof. Victor F. Hess

THE Nobel Prize for physics for 1936 is divided equally between Prof. Victor F. Hess of Innsbruck for his work on cosmic radiation and Dr. C. D. Anderson of Pasadena for his discovery of the positron. It was Prof. Hess's experiments in manned balloons in 1912 which first definitely proved the existence of penetrating rays which enter the earth's atmosphere from outside. This conclusion followed from the discovery that the ionization in a closed ionization chamber at a height of 4,000 metres was greater than at sea-level, and above this increased rapidly. Hess also showed that the ionization due to this new radiation decreased neither during the night nor during an eclipse of the sun, thus showing that the rays cannot come directly from the sun, so long, at any rate, as the rays travel in straight or nearly straight paths. It was this pioneering work of Hess which led to the view that the penetrating rays were really cosmic in origin. In more recent years, Prof. Hess, besides contributing much to the subject of atmospheric electricity, has paid especial attention to the study of the variation of the intensity of the cosmic rays with time. This work demands very accurate measurements over a period of years, since the variations are complicated and small in magnitude. From these and other similar investigations, a small daily variation has been established with certainty, and probably also a quite small variation with sidereal time of the order of 0·1 per cent. The existence of such an effect was predicted by Compton as a consequence of the assumption that the rays had their origin outside the Galactic System, and about the expected variation was found from the measurements of Hess and Steinmaurer. Prof. Hess's work on cosmic rays has extended over a period of more than twenty-five years, and it is with very great pleasure that all workers in this field now see this work receiving its due recognition.

Dr. C. D. Anderson

DR. ANDERSON's discovery of the positive electron or positron arose also through the study of cosmic radiation. During an investigation of the properties of the rays by means of a cloud chamber in a strong magnetic field, Anderson found certain photographs which revealed the tracks of particles with about the same ionization, and so about the same mass, as electrons, but which were curved by the magnetic field in the direction corresponding to particles with a positive charge. This exceedingly important result was published in 1932 as a short communication to *Science*, in which Dr. Anderson wrote: "For the interpretation of these effects it seems necessary to call upon a positively charged particle having a mass comparable with that of an electron." Thus a new member was added to the select list of fundamental particles. Subsequent work has shown, not only that about half the cosmic ray particles are positrons, but that they are also often produced as one of the partners of pairs of positive and negative electrons, when gamma-rays of high energy are absorbed by matter. These positrons do not live long, as they readily combine with other negative electrons to form more radiation. The discovery of the positron provided the final proof of the validity of Dirac's theory of the electron, for this theory requires the existence of just such a particle.

Dr. Anderson has also contributed greatly to the study of cosmic radiation itself, particularly by his work on the energy spectrum of the rays and of their energy loss in passing through matter. In connexion with the latter, he has recently shown that electrons with energies at least up to 3×10^8 electron volts do suffer the large radiation energy losses which are predicted by theory. During the last year, Dr. Anderson took his apparatus to the top of Pike's Peak at an altitude of 4,300 metres, and there obtained a large number of cosmic ray photographs by the counter-controlled method. Among these are some of the finest shower photographs yet taken. It is interesting to note that Dr. Anderson's communication to *Science*, announcing the apparent existence of a positive electron, was only the fourth paper published by him. Dr. Anderson, who is only thirty-one years of age, must certainly be the youngest experimenter in recent decades to make a discovery of such first-class importance; and now he is also to be congratulated on being surely one of the youngest experimental physicists to receive a Nobel prize.

Edward Meyrick, F.R.S.

Mr. Edward Meyrick will reach the age of eighty-two years on November 24, and his many friends and correspondents all over the world will join with Nature in good wishes and congratulations on his effective life's work. In 1927, when awarded the Captain Scott Memorial Medal by the South African Biological Society, for his study of South African Microlepidoptera, the president justly remarked that "Mr. Meyrick's is an example of what can be done by a single individual, unsupported, with no financial backing, but devoted to a task that fills his life". Meyrick is a Wiltshireman, still residing at Thornhanger, Marlborough. He was a boy at Marlborough College from 1868 until 1873, and a classical scholar of Trinity College, Cambridge. From 1877 until 1886 he was a schoolmaster at Sydney, Australia, and at Christchurch in New Zealand. He returned to Marlborough College as an assistant master in 1887 and continued there until his retirement in 1914. During the last fifteen years of that period, he was president of the Marlborough College Natural History Society, which has been an inspiration to so many young naturalists, many of them now men of distinction. Marlborough is indeed one of the most fortunate of schools, situated in the beautiful valley of the Kennet between Savernake Forest and the wide and open chalk downs of Wiltshire, with its varied fauna and flora. The country-side is famous for dykes, barrows and hill-forts, and the county contains Stonehenge, Avebury, Old Sarum and Silbury; while the British 'mount' of Marlborough stands within the historic grounds of the College, once a British fort, once a castle, once a mansion, once the "Castle Inn" with its memories of Pitt, now a school, and always famous.

The duties of an assistant master at a public school are so arduous and exacting that it is rather rare for a schoolmaster to achieve the distinction of becoming a fellow of the Royal Society. Meyrick was elected in 1904, largely for his work on Australian Lepidoptera. About nine years later he published his "Handbook of British Lepidoptera" (Macmillan), and in 1927 "A Revised Handbook of British Lepidoptera" (Watkins and Doncaster). In these books Meyrick broke away from the older classification based on fugitive characteristics such as wing patterns and colours, and he depended largely, but not entirely, on the more permanent forms of the veins or neurations of the wings. He was familiar with the Microlepidoptera of South Africa, Australia and New Zealand, for he was a great traveller, and a student of the moths and butterflies of the whole world. His study of the insects of Australia and New Zealand caused him to reject the Wegener hypothesis that those regions, once united, had drifted a thousand miles apart. Meyrick had a large viewpoint as a naturalist, and the following have been termed, by Comstock, Meyrick's Laws, though perhaps laws is not quite the right word: "No new organ can be produced except as a modification of some previously existing structure." "A lost organ cannot be regained." "A rudimentary organ is rarely re-developed." Most of Meyrick's work will be permanent; other work has come and more will originate from the many pupils to whom he has handed on the lamp of wisdom and the torch of enthusiasm.

Dr. F. Simon

Dr. F. Simon, who has been appointed to succeed Prof. A. C. G. Egerton as reader in thermodynamics at Oxford (see p. 895), took his degree in Berlin in 1921. He was *Privatdozent* and extraordinary professor of physics there until 1931. From 1931 until 1933 he was director of the physical-chemical institute of the University of Breslau. He was in California for six months in 1932 as a visiting professor. During the last three years he has been working in the Clarendon Laboratory at Oxford on low temperature research, particularly on the production of very low temperatures by the magnetic cooling method, and on the properties of matter in the neighbourhood of the absolute zero.

J. L. Macadam (1756–1836)

The centenary of the death of John Loudon Macadam, which occurs on November 26 (see p. 869), is a reminder of the debt we owe to that group of men who at a critical time in our industrial history were instrumental in making vast improvements in our means of transport. As one of this group, Macadam has a place beside Brindley, the Duke of Bridgewater, Telford, Rennie, Metcalf, Smeaton and others. Macadam was born in Ayr on September 23, 1756. He lost his father in 1770 and as a boy of fourteen years of age was sent to an uncle in New York. Thirteen years later he returned home comparatively well off, and settled down to the life of a country gentleman in his native country. It was as such he began his experiments on road-making, which were eventually to bring him fame if not fortune. It is not a little extraordinary, however, that his main work was done after reaching the age of sixty years, when he was made surveyor-general of roads to the Bristol Turnpike Trust. He resigned this position when sixty-nine, and two years later Parliament appointed him Surveyor-General of Roads. This position he held until his death at Dumcrieff House, Moffat, on November 26, 1836. At one time it is said he had no fewer than three hundred surveyors working under him. The importance of his work was fittingly commemorated at Ayr on October 30 last, when a bronze tablet erected by the Institution of Municipal and County Engineers was unveiled by Mr. Hore-Belisha, the Minister for Transport, and a paper on "John Loudon Macadam, Roadmaker" was read by Mr. G. S. Barry, the County Surveyor, Ayrshire.

Memorial to the late Sir Walter Fletcher

ON November 11, the subscribers to the Sir Walter Fletcher Memorial Fund were invited by the Medical Research Council to view Miss Dora Clarke's portrait-bust of the late Sir Walter Morley Fletcher, secretary of the Council from 1914 until 1933. The ceremony was held at the National Institute for Medical Research, Hampstead, in the library of which the bust is to be placed permanently. Lord Balfour of Burleigh, chairman of the Council, presided. The chief speakers were Prof. G. M. Trevelyan and Sir Frederick Gowland Hopkins, the former dealing mainly with the personal aspect and the latter with Fletcher's scientific and administrative work. Sir Henry Dale, director of the Institute, then accepted custody of the bust. The total amount contributed to the Fund by more than five hundred separate subscribers is approximately £2,300. The remainder, after meeting the cost of the personal memorial, is being used for a Walter Fletcher Memorial Laboratory. This is being constructed at the Farm Laboratories of the National Institute at Mill Hill, and is to be used for research work in nutrition.

Grassland of Great Britain

AT a meeting of the Engineers Study Group on Economics held on November 10, Prof. R. G. Stapledon discussed methods of dealing with the problem of grassland in Great Britain. He exhibited a map of Wales, the result of a recent survey, and pointed out that there are only 16,000 acres of proper pastures (rye grass), although at least a third of the 153,000 acres under bracken is of high potential value. To make the best use of the 18,000,000 acres of rough hill grazing ground in Great Britain, Prof. Stapledon considers that it is necessary for the State to acquire and develop it. This, he believes, would be economically feasible over a period of 25–50 years, beginning at once with an area of not less than 200,000 acres. Agriculturally, the potentialities of the hill land not above the 150 ft. contour (in all, more than 14,500,000 acres) are enormous, at least 20 per cent of that area being amenable to radical improvement. Lowland grass could be used for drying and for wintering, and improved upland grass for summering, and the plough, oats and fatting crops everywhere. Roads and tracks should be constructed in connexion with land improvement and afforestation. Sir Richard Paget, who presided at the meeting, expressed his appreciation of the pioneer work of Prof. Stapledon, and Lord Northbourne, in opening the discussion, stressed the importance of preserving individual initiative.

Temples and Caste in Travancore

THE decision of the Maharajah of Travancore, announced by proclamation authorizing the opening of the temples controlled by the State to all Hindus, according to a Delhi dispatch in *The Times* of November 16, has been hailed by progressive opinion in India as "the greatest reform of Hinduism since Ramanuja's days". By this drastic action, which at once obliterates caste distinction in right of access to the sacred places of religion, and removes one of the most strongly resented marks of inferiority in the outcastes, the State of Travancore has opened a way to political unity which Hinduism at large would do well to accept as a guide and example. The exceptional position of the Rajah in relation to the State religion has endowed him with a power of initiative that was open to few others in India, and perhaps least of all to the British Raj; but whether the example of Travancore will be followed elsewhere will doubtless depend in no small degree upon the religious and political reaction to so serious an innovation. It is said that conservative opinion has already criticized the reform as rash and unsound, while maintaining that the views of Hinduism outside Travancore should have been considered—a claim, of which, in view of past events, it would be difficult to vindicate the political wisdom. On the other hand, the Nationalists and leading members of the Congress, with Mr. Gandhi, have hastened to congratulate the head of the State of Travancore on his decision.

Guide to Ancient Monuments

MR. ORMSBY-GORE'S promise on relinquishing office as First Commissioner of Works to complete the manuscript of that part of the official guide to ancient monuments then in hand, has now been redeemed by the publication of the volume covering East Anglia and the Midlands ("Illustrated Regional Guides to Ancient Monuments under the Ownership or Guardianship of H.M. Office of Works", vol. 3, East Anglia and Midlands. By the Right Hon. W. Ormsby-Gore. London: H.M. Stationery Office. Pp. 72. 1*s*. net). In method of treatment of both the prehistoric and the historic sections this volume follows the plan of its predecessors; but matter of general application in the various periods, which has been given in the earlier volumes, has been omitted. Although it may be agreed that nothing can make a stronger appeal to the historic imagination than Stonehenge and Avebury, which have already been described, the present volume in no other respect falls below those already issued in the importance and interest of the monuments which it includes. As a source of information relating to the industries of neolithic man, Grime's Graves is without rival; while the circle of Arbor Low in Derbyshire, and the megalithic barrows of the Cotswolds each hold a place in British prehistory, of which the importance needs no emphasis. It may be noted, however, that the latter are counted the oldest monuments under the guardianship of the Office of Works. Verulamium, since Dr. Mortimer Wheeler's excavations, is unique both as a British and a Romano-British site. In historic periods the abbeys of Shropshire and the castles, such as Framlingham, stand out among medieval buildings; while Kirby Hall, Northants, is one of the most important of the large country houses of Elizabethan and Jacobean times. For the first time, historic buildings belonging to the Crown appear. These are the Tower, Hampton Court, Kensington Palace, and the Chapter House of Westminster. Of the various periods into which English prehistory and history fall, the Saxon alone does not appear among the historic monuments under protection.

Ethnology of the Far East

THE authorities of the Raffles Museum, Singapore, have added a new series, to be known as Series B, to the Museum Bulletin. The present publication, which will now become Series A, hitherto has been devoted almost entirely to communications of a biological character. The new series will be anthropological, and for some time to come will be devoted largely to publication of the results of a scheme of research in the prehistory of the Malay Peninsula, for which the Carnegie Corporation of New York has voted a subvention extending over a period of three years. In the first issue of the new series are three reports on recent excavations—the first in Kedah by Mr. H. D. Collings, the second in a cave in Bukit Christamani by Mr. M. F. W. Tweedie, and the third on kitchen middens at Guak Kepeh, Wellesley Province, by Dr. P. V. van Stein Callenfels. The most important, as well as the longest, communication is from Dr. van Stein Callenfels, who, in "The Melanesian Civilization of Eastern Asia", contributes a detailed analysis of the Hoabinian stone age culture, so called from the early culture first distinguished in Tonkin, which he traces throughout the East so far as observed from China and Japan to Celebes, and analyses into three stages, in which he sees evidence for contacts between a people of a palæolithic type of culture with another in a protoneolithic stage. In incorporating the new evidence obtained under the present scheme in his analysis, and at the same time making use of the evidence afforded by earlier excavations in the Malay Peninsula, notwithstanding their defects in method, Dr. van Stein Callenfels also turns to the discussion of the position of Wadjak man, to whom he is inclined to assign a date later than the Pleistocene, but to regard him as a very old representative of the Melanesoid culture.

The Consumption of Statistics

IN his inaugural address on November 18 as president of the Royal Statistical Society, Lord Kennet urged the necessity for a more effective consumption of statistics. He affirmed that statistics—in the broad sense of the collection and methodical arrangement of facts—provide the one indispensable food from which the organs of Government can derive the motive power for the right conduct of the business of governing the nation. Decisions made without adequate statistical study on questions of the magnitude and complexity with which modern Governments have to deal, are not in the least likely to be even approximately correct, and the resulting policies and measures would be little better than the medicine-man's sympathetic magic carried out by incantation. Without doubt, then, the Government ought to be the most substantial consumers of statistics. If the Government consumes statistics—and it undoubtedly does to some extent both consume and digest them—the results of Government action seem to show that the metabolism is defective. What part of the organism is at fault? Lord Kennet classified the effective organs of Government as the Press, the wireless, the Civil Service, the Cabinet, the House of Commons, the voters at election time, the local authorities. Which of these is to blame? The fault must be directly attributed to the executive government, but the blame lies fundamentally with their masters, the people, whose national predilection is for 'muddling through', and who believe that scientific study has little practical value. Theory and practice are in reality not opposed but complementary to one another, and the widespread belief to the contrary is responsible for much of the mental lethargy which makes our conduct of affairs what it is—too often a fortuitous muddle.

Coal Gas Research

AT the eighth Autumn Research Meeting of the Institution of Gas Engineers held in London on November 3–4, the papers showed current trends of thought in the gas industries. The thirty-ninth report of the Joint Research Committee of the Institution and the University of Leeds gave the first instalment of a study of the complete gasification of coal in oxygen-steam mixtures. Such a process, if successful, might make the industry less dependent on the choice of coal, and less would be required. At the same time it would have far-reaching consequences on the distributions of fuel. This report contained a study of the conditions within a fuel bed during gasification. Three papers dealt with the sulphur impurity in coal gas. Coal gas is the purest fuel in general use, but this very purity renders possible its use in flueless apparatus, and the small quantity of sulphur compounds present may become noticeable even if innocuous. The paper shows that the coal gas of the future may be purified of sulphur compounds to a degree hitherto unknown. The paper by H. Hollings on the formation and removal of gum in coal gas reveals the solution of a baffling problem which has arisen following the use of the practice of drying gas before distribution. Traces of unsaturated hydrocarbons—almost inconceivably minute—condense or polymerize to form gummy substances which may cause trouble in appliances. The solution of this puzzle is a marked achievement of industrial chemical research. A. R. Bennett and H. Hartley described an instrument for measuring the radiation from heating appliances, which should be serviceable for other uses.

Air-Conditioned Flats

EATON HOUSE, Upper Grosvenor Street, London, W.1, has been converted into a building containing thirty luxury flats. They are equipped for electric cooking and refrigeration, and hot water is supplied from a central hot water plant in the basement. We learn from the *Electrician* of November 6 that each tenant has an air-conditioning plant completely under his own control. Both the temperature and humidity of the air can be adjusted by the tenant to any value he pleases. In each flat there is a condensing unit working in conjunction with an air-conditioner, consisting of a slow-speed fan and motor, heating coils, cooling and dehumidifying coils, air filter and humidifying spray for winter use. The air-conditioners are housed in cupboards in the kitchens of each flat and cleverly concealed. Each conditioner passes approximately 1,300 cub. ft. of air per minute. About twelve complete changes of air per hour are provided in the rooms. It is essential that the plants be practically inaudible as they are in operation twenty-four hours a day. This has been effected by mounting the units in pedestal anti-vibrators. The filtered fresh air enters through grilles in the walls, and as there is no need to open windows street noises, grime and dust can be kept out. A small wall panel in the hall of each flat carries the temperature and humidity control apparatus. It consists of a thermostat, humidistat and change-over rotary switch. An advantage of individual control is that if a flat be left empty, the entire plant can be switched off and thus save running costs. The equipment was designed and installed by York, Shipley, Ltd. of North Circular Road, London, N.W.2. For the electricity the tenants pay a small quarterly fixed charge and ½*d*. per unit.

Testing Switchgear

THE safety of every electricity supply system depends on its switchgear always being ready to operate. The main switches (circuit-breakers) must always be capable of making and breaking the current, and still remain fit for use. The development of the grid system has proved the necessity of being able to 'clear' a fault even when fed by enormous currents. For many years, the firms now constituting Associated Electrical Industries have had extensive experience of short-circuit tests made with generators having capacities up to 80,000 kilovolt amperes. In an article in *Electrical Industries* of October 14, a description is given of a testing station having a generator capable of giving 2,500,000 k.v.a. on short circuit. In order to meet the demand for more tests and for tests at higher powers, the companies interested combined to form a separate company known as the Switchgear Testing Co., Ltd., which now owns and operates the plant on their behalf. The testing station is situated at Trafford Park, Manchester. Ample space had to be provided to ensure personal safety, and, when 'testing to destruction', to avoid damage to property by explosion and fire. The station has three testing areas; two are covered over and used for testing up to 33 kv., and one is an open area, testing up to the grid voltage of 132 kv. The station has a complete equipment for measuring and recording phenomena. Its electromagnetic oscillograph has sixteen elements and is probably the only oscillograph of this kind in the world. It is satisfactory to know that these companies have taken a leading part in conjunction with other firms both in Great Britain and abroad in producing a standard specification for procedure in testing circuit breakers which is recognized internationally.

Marine Work in Ceylon

THE Administration Report of the Marine Biologist, Mr. A. H. Malpas, for 1935 (Part IV—Education, Science and Art (G), Marine Biology: published May 1936) shows that the inspection of the pearl banks again reveals an absence of sufficient spatfalls of both southern and northern paars to provide fisheries within the next three years, despite the presence of sexually mature oysters in sufficient quantity to repopulate the banks. Although conditions of the kind have always been attributed to adverse currents carrying away the free-swimming larvæ into deep water where they are lost, there seems to be some justification for the belief that hydrobiological conditions in the Gulf of Manaar are the more important factors in so far that adult pearl oysters can be stimulated to maximum spawning only under particular conditions of salinity and temperature, which are the exception, rather than the rule, and therefore the pelagic larvæ are not developed in sufficient numbers to produce spatfalls except when these conditions obtain. The scheme referred to in last year's report for the establishment of a Fisheries Research Station at Colombo combined with an aquarium has been modified, and the suggested aquarium available for the public abandoned, a more comprehensive scheme with experimental aquaria and provision for a fish hatchery on a fairly large scale being substituted. This will provide not only for facilities for investigating the bionomics of marine and freshwater animals of economic importance but also for experiments in hatching and rearing the more important freshwater food fishes.

The London School of Hygiene and Tropical Medicine

A REPORT by Sir Austen Chamberlain, chairman of the Court of Governors, giving a short account in non-technical terms of the work of the London School of Hygiene and Tropical Medicine (incorporating the Ross Institute) for the information of those who contribute to its maintenance, has been issued to subscribers. Commencing with a short history of the establishment of the London Tropical School in the hospital of the Seamen's Hospital Society at the Royal Albert Dock, its removal to Endsleigh Gardens, and finally its incorporation in the London

School of Hygiene in Keppel Street, Gower Street, the work of the School for the year ending July 31, 1936, is surveyed. The teaching and research work of the various departments are briefly summarized, as well as additions to, and organization of, the library and museum. The incorporation in the School of the Ross Institute of Tropical Hygiene, and the work this branch is doing, are also dealt with. The report is illustrated with a number of plates, and lists of subscribers and of research publications are included.

Work of the Building Research Board

AT the Building Exhibition, Olympia, 1936, an exhibit was arranged to give the public an opportunity of seeing the nature, methods and results of the investigations of the Building Research Board being carried on at Watford, at Teddington and at Princes Risborough. The D.S.I.R. has issued a descriptive pamphlet, "Building Research Exhibit—Olympia 1936" (Dept. of Scientific and Industrial Research, S.W.1), containing a short explanatory statement of the nature of the work being done in each section and briefly indicating the special features of the exhibit. One of these showed samples of light-weight aggregates with a chart of their physical properties and the methods of testing used. In another section their value for thermal insulation in building construction was demonstrated.

Genetics of the Pig

A MONOGRAPH by A. D. Buchanan Smith, O. J. Robison and D. M. Bryant dealing with this subject (Reprint from *Bibliogr. Genetica*, 12. The Hague: M. Nijhoff) is a summary of all that is known of the genetics of pigs and will be very serviceable to the geneticist as well as the practical breeder. Beginning with the chromosome number and the inheritance of colour in wild and domestic breeds, it goes on to hair and skin characters, blood groups, disease resistance, mental traits, sterility, intersexuality, numerous abnormalities and defects, conformation, productive qualities and methods of improvement in different countries. Twenty-one photographs of different breeds of pig are followed by a bibliography of 28 pages and an index which makes the information readily available.

The *Zoological Record*

THIS essential instrument of zoological research, published under the auspices of the Zoological Society of London, still requires further financial support. The statement of the 'Record Fund' in the report of the Council of the Zoological Society for 1935 shows that the sums received from the contributing societies were just sufficient to meet the loss on vol. 71 for 1934, and that the continuation of the *Zoological Record* is made possible only by the support given to it by the Zoological and other contributing societies. The British Association Committee formed for the support of the *Record* proposes that an annual grant of £50 should be repeated in 1937.

Breeding of King Penguins at Edinburgh Zoological Park

IN 1919, probably the first king penguin bred in captivity was hatched and reared in the Scottish National Zoological Park in Edinburgh, and since that time the number has been added to almost annually. Last year two were reared, and at present there are four king penguin chicks, all hatched at about the same time late in the summer. The work of incubation and rearing the chick is shared by both parents, but the part taken by the mother is almost negligible, the father being responsible for about nine-tenths of the performance.

Wild Animals in Poland

IN the Eastern Carpathians, the *Quarterly Information Bulletin* (Krakow, 1936) states, there still exist about three hundred bears, of which four were killed in 1935. The elk herds now number more than a thousand individuals, their welfare having been aided by the disappearance of an epidemic from which the herds suffered in the previous year, and from a decision to stop the cutting of timber in the elk territories, with the result that the herds, formerly compelled to emigrate, were able to winter in their established districts.

Child Neurology Research

A SPECIAL committee is to be formed with a grant from the fund established by Colonel Michael Friedsam and under the direction of Dr. Bernard Sachs, of New York, to stimulate research in child neurology and allied subjects. The committee is to be composed of two neurologists besides Dr. Sachs, two pædiatrists, one orthopædic surgeon and two laymen. Further information can be obtained from Dr. Bernard Sachs, 116 West Fifty-ninth Street, New York.

Canadian Minerals

THE mineral wealth of Canada is fully reviewed in the annual publication of the Department of Mines ("The Canadian Mineral Industry in 1935." Ottawa. 25 cents). Metals and metallic ores, industrial minerals and fuel are each arranged alphabetically, and under each is a review of producing localities, production, trade and prospective producing localities. Much important information is thus given in a readily accessible form.

Presentations to two Cambridge Botanists

AN executive committee has recently been formed at the University of Cambridge with the view of approaching resident members of the University, past students of the Botany School, and other British and Dominion botanists for subscriptions to a fund for obtaining the portraits, in oils, of Sir Albert Seward, formerly professor of botany, and Dr. F. F. Blackman, formerly reader in botany in the University, both of whom have now retired, for presentation to them. The presentations are intended as a token of personal esteem and appreciation of the great services they have rendered both to botany and to the University. Cheques should be sent to Prof. F. T. Brooks, Botany School, Cambridge, and should be crossed "Portrait Fund".

Announcements

PROF. F. G. DONNAN, professor of chemistry in the University of London, and Sir Albert Seward, formerly professor of botany in the University of Cambridge, have been elected honorary fellows of the National Institute of Sciences of India.

THE next International Congress of Microbiology will be held in 1939 at Atlantic City, New Haven, U.S.A.

THE Medical Research Council has made the following awards: Senior Fellowships to Dr. Frederick Murgatroyd, lecturer in protozoology in the Liverpool School of Tropical Medicine; and Dr. Cecil Hackett, recently engaged in investigations in the Northern Territory of Australia. Dr. Murgatroyd will work in West Africa on the chemotherapeutic treatment of trypanosomiasis, and Dr. Hackett in East Africa on the pathology and clinical manifestations of yaws. Junior Fellowships have been awarded to Gilbert B. Ludlam, clinical assistant in the Sheffield Royal Hospital, and Joel N. Strauss, formerly house physician in the Hospital for Tropical Diseases, London. These are tenable for three years, during the first two of which the holders will undergo training in Great Britain in tropical medicine and in the use of research methods.

THE following appointments and promotions have recently been made in the Colonial Service: W. E. Lewis, to be assistant conservator of forests, Nyasaland; T. W. Summers, to be assistant conservator of forests, Nigeria; L. C. M. Wedderburn, to be assistant conservator of forests, Nigeria; J. E. Turnbull, to be veterinary officer, Tanganyika; T. Bell, to be assistant manager, Government Stock Farm and Agricultural Station, Acre, Palestine; T. A. des Iles, to be veterinary officer, Tobago; D. P. Le Jeune, to be engineer, Water Supply Section, Geological Survey, Nigeria; W. F. Gwilliam (inspector of plants and produce, Gold Coast), to be agricultural officer, Nigeria; R. G. M. Willan (formerly assistant conservator of forests, Nigeria), to be assistant conservator of forests, Nyasaland; G. W. Butcher (chief electrician, Electrical Department, Falkland Islands), to be broadcast officer, Gold Coast; R. W. Donkin (inspector of produce, Zanzibar), to be inspector of produce, Gold Coast.

A STATE-SUPPORTED office for industrial hygiene has been established in West Virginia. Its first concern will be the supervision of silicosis.

THE central offices of the International Council for the Exploration of the Sea have been removed to the Charlottenlund Castle. The new address, therefore, is Charlottenlund Slot, Charlottenlund, Denmark, or, Postbox 20, Charlottenlund, Denmark.

WE are informed that among the presidents of Associations forming the executive committee of the International Union of Geodesy and Geophysics (see NATURE, Oct. 10, p. 650), there should have been included the name of J. A. Fleming, president of the International Association of Terrestrial Magnetism and Electricity. Prof. la Cour, one of the secretaries of the Associations, is from Denmark, and is succeeded by A. H. R. Goldie (Great Britain).

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

A University demonstrator in mineralogy and petrology in the University of Cambridge—Dr. F. C. Phillips, Department of Mineralogy and Petrology, Downing Street, Cambridge (November 24).

A head of the Mining Department in the Whitwood Mining and Technical Institute—The Secretary, Education Offices, Castleford, York (November 28).

A scientific officer (electrical engineering or physics) in the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (Quote A.154.(a)) (November 28).

A research chemist in the Department of Clinical Investigations and Research in the Manchester Royal Infirmary—The Director (November 30).

A lecturer in biology in the London (Royal Free Hospital) School of Medicine for Women—The Warden, 8 Hunter Street, Brunswick Square, W.C.1 (December 4).

Chemists in the Department of the War Department Chemist—The Under-Secretary of State (C.5), The War Office, S.W.1 (December 5).

A temporary assistant (Grade III) in the Admiralty Chemical Pool for work on metals at an Admiralty establishment in Sheffield—The Secretary of the Admiralty (C.E. Branch), Whitehall, London, S.W.1 (quote No. *C.E.*7123/36) (December 11).

A principal of the Kadoorie Agricultural School, Tulkarm, Palestine—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, London, S.W.1 (December 15).

A second assistant petroleum technologist to the Government of Trinidad and Tobago—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1 (December 17).

A professor of applied chemistry in the Andhra University, Waltair, South India—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (December 20).

A professor of chemistry in University College, Southampton—The Registrar (January 1).

A University professor of mechanical engineering in Benares Hindu University—The Pro-Vice-Chancellor (January 15).

A scientific research fellow in Girton College, Cambridge—The Secretary (February 1).

An executive engineer for the Public Works Department of Sierra Leone—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1 (Quote M/4572).

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 887.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Nature of the Excretion of Nitrogen Compounds from Legume Nodules

FURTHER to our earlier communications concerning the excretion of nitrogen compounds from the nodules of leguminous species, I wish to add the following: a distinct excretion occurs only in media capable of absorbing the excreted amino acids. In water cultures, whether plain or filled with glass beads, the excretion is quite negligible. Addition of cellulose to the liquid medium results in a clearly detectable excretion. A much more powerful excretion occurs, however, in media consisting of kaolin, sand or soil. These materials absorb the excreted amino acids to such an extent that their extraction from the medium with water is very tedious and difficult. On the basis of these observations, it seems that the distribution of the nitrogen compounds between the nodule and the external medium is determined by an equilibrium. The presence of absorbing materials shifts this equilibrium to the side of the medium, and causes the excretion to occur. On the other hand, the host plant also takes up nitrogenous matter from the nodules. The equilibrium is therefore a very complicated one, and the rate of excretion depends largely on the ability of the host plant to utilize the nitrogen compounds fixed and synthesized in the nodules. Our observation that the rate of excretion is the higher, the greater the quantity of sand, is in accordance with this view. We have shown earlier[1] that the air content of the medium influences largely the function of the nodule, although it apparently has no specific effect on excretion, as we assumed earlier.

TABLE I.

3-litre Woulff's bottles; 3·4 kgm. quartz sand; period of growth: May 2–June 9, 1932.
Nitrogen-free nutrient solution. The sand contained initially 2·7 mgm. N per kgm. sand.

	Culture No.	Inoculation	Dry weight		(N mgm.)*			Total fixed N (mgm.)	Excreted N (% of total fixed N.)
			Peas	Barley	Peas	Barley	Sand		
Exp. 1. One pea + one barley in each flask	1	Strain H IV	1·462	1·791	41·8	31·6	89·0	162·4	74·3
	2	,,	2·048	1·660	55·8	21·7	77·4	154·9	64·0
	3	,,	1·382	1·432	42·6	24·4	93·9	160·9	73·5
	4	,,	2·400	0 655	60·7	13·0	67·6	141·3	57·0
	5	None; control	0·297	0 063	6·4	0·7	10·0	—	—
Exp. 2. Two peas in each flask	1	Strain H IV	2·564	—	74·5	—	79·4	153·9	51·6
	2	,,	4·644	—	130·1	—	87·2	217·3	40·1
	3	,,	5·788	—	138·9	—	91·3	230·2	39·7
	4	,,	5·225	—	123·4	—	96·7	220·1	44·0
	5	None; control	0·512	—	14·4	—	9·5	—	—

* All nitrogen values for the inoculated cultures are given after subtraction of the corresponding values for the uninoculated controls.

TABLE II.

Sown May 22, 1934; peas harvested August 4, potatoes September 5. Nitrogen-free nutrient solution.

	4 peas + 1 potato		8 peas + 1 potato		Control not inoculated; 4 peas + 1 potato	
	Dry weight (gm.)	N (mgm.)*	Dry weight (gm.)	N (mgm.)*	Dry weight (gm.)	N (mgm.)*
Pea crop	7·117	169·1	25·310	640·2	1·495	30·4
Potato crop, tops	13·832	330·3	17·510	396·9	2·957	53·9
,, tubers and roots	25·410	287·9	33·173	332·1	8·940	92·4
,, total	39·242	618·2	50·683	729·0	11·897	146·3
Nitrogen in the sand		90·1		115·5		66·6

* Controls not subtracted.

Another fact which is likewise in accordance with the above view is that the rate of excretion seems to increase in associated cultures of inoculated legumes and some non-legumes capable of utilizing the excreted nitrogen compounds. In our sterile culture system in quartz sand, wheat and barley utilize the excreted diamino acid, but only very little aspartic acid. However, even under these conditions, for example, in associated cultures of peas and barley, the amount of nitrogen in the barley and in the sand is generally higher than the amount of nitrogen in sand in cultures of peas alone. This is shown in Table I.

The excretion is particularly powerful in ordinary pot cultures of legumes and non-legumes, when other bacteria decompose aspartic acid and thus enable the non-legumes to utilize the entire quantity of excreted nitrogen. This is especially the case in cultures of peas and potatoes. The latter plant takes up enormous amounts of nitrogenous matter, and may deprive the pea of nitrogen to such an extent that its growth is seriously impaired. Table II shows that the injury to the pea is the greater the less the number of peas in the culture.

It will be seen that in a culture with four peas to one potato plant, the potato has received from the pea nodules about 3·5 times more nitrogen than the peas themselves. Nitrogen in the potato crop has thus increased by 471·9 mgm. and in peas by 138·7 mgm. (after subtraction of the controls). The pea nodules have thus fixed nitrogen mainly for the benefit of the potato, at the expense of the pea. In another pot experiment in which low-nitrogen loam soil was used as the medium, the potato obtained from the nodules ten times more nitrogen than the peas.

Oats, wheat or barley are not able to deprive the peas of nitrogen to a similar extent, although in associated cultures of even these grasses and peas the growth of the latter is impaired with decreasing ratio of peas to non-legumes. This observation, made by us some years ago, is easily explained on the basis of the above view concerning the nature of excretion.

The extent of nitrogen fixation by inoculated legumes is thus not determined solely by the amount of nitrogen taken up by the legumes but also by the amount of nitrogen which is excreted from the nodules. I therefore wish to propose the following terms for general use:

Total fixed nitrogen=Nitrogen given up by the nodules to the host plants and the medium.

Extent of excretion=amount of nitrogen excreted into the medium, as a percentage of the total fixed nitrogen.

In associated cultures the excreted nitrogen naturally also includes the amount of nitrogen received by the non-legumes from the nodules of the legumes.

Our experiments show that the extent of excretion varies greatly with different strains of the nodule organisms. Preliminary observations also seem to indicate that a relatively low nitrate fertilization lowers the excretion much more than the nitrogen fixation. Further work is needed to throw more light on this question.

Further to our earlier communications on the nature of the excreted N-compounds, it should be mentioned that the excreted aspartic acid is the *l*-form. Small amounts of fumaric acid could also be isolated from the extract. The excreted amino-nitrogen can be determined quantitatively, both by the van Slyke method and also with ninhydrine at *p*H 7. This obviates the necessity of concentrating the extract.

Our work on the excretion of the nitrogen compounds from the nodules and on associated cultures of legumes and non-legumes will be published in the *Journal of Agricultural Science*, while our investigations on the chemical nature of the excreted compounds will be described in the *Biochemical Journal*.

Identification of Vitamins by Molecular Distillation

WHEN oils containing vitamins are submitted to molecular distillation[1], the fractions removed as the temperature rises contain successively more vitamin until a maximum is reached, after which the potency falls rapidly to zero because all the vitamin has been eliminated. The elimination follows a simple law and the ideal *elimination curve* possesses a slightly skew shape which is easily recognizable. Deviations from the shape indicate imperfect conditions of distillation or the presence of more than one form of the vitamin. The maximum of the curve can be located with an accuracy of ± 2° C., and is as definite a characteristic as a boiling point, if less precise. Separate elimination curves can be detected for more than one material if the maxima are 5° C. apart. When two potent materials yield different maxima, it is proof that they are different substances. Coincident maxima provide only partial evidence that the substances are identical. When oils containing traces of many impurities are distilled, their maxima occur in a fixed order, and if one can be identified, the others may be recognized. This enables dyes, etc., to serve as distillation pilots. For example, when traces of Celanthrene Red 3B and dimethyl-amino-anthraquinone are distilled with an oil containing the free vitamins A and D, the reddest fraction is found to hold the most vitamin A, and the bluest, the most vitamin D. The elimination curves of the two vitamins correspond almost exactly with those of the dyes (Fig. 1).

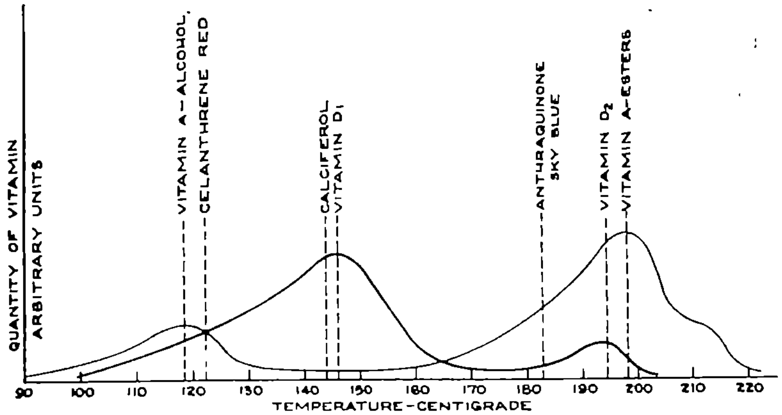

FIG. 1.

Elimination curves can be found more accurately if the distillation is made from an oil which yields a constant quantity of distillate for each equal increment of the absolute temperature. Such an oil can be made by esterifying glycerin with a mixture of fatty acids. By mixing various fish oils with this constant yield oil, it has been found that the vitamin A in the cod liver and halibut liver oils exists almost entirely in the form of esters. The distortion of the curve shows that the esters are derived from most of the fatty acids present. A very small quantity of vitamin A alcohol is also found, the quantity increasing with the lower grades of oil. The vitamin D in cod liver oil yields a maximum halfway between the vitamin A alcohol and esters. The maximum is accompanied by a second high-boiling maximum which grows in relative size as the distillation is performed more quickly and carefully. Evidently vitamin D occurs partly free and partly as a mixture of esters, the esters surviving for only a few seconds at the temperature of distillation.

The maxima of free vitamin D and calciferol are found to coincide within 5° (Fig. 1). Nevertheless, when a mixture of the two is distilled, the maximum is not increased in height, but instead, two new maxima appear separated by 20°. Evidently calciferol and free vitamin D react, producing other antirachitic substances.

Recently, by studying some substituted di-aminoanthraquinones, it has been determined that the maxima are shifted about 5° C. for each additional carbon atom in the side chain. Calciferol is reported by Windaus *et al.*[2] to differ from vitamin D_3 by one carbon atom and one double bond in the side chain. It should be possible to settle the point by measurements of the elimination maxima; and this work is in progress.

The elimination method is being applied to the antirachitic vitamins in various fish oils; the distribution of the esters is found to differ greatly from one fish to another. Should there be more than one form[3] of the vitamin (in yellow fin tunny liver, for example) and if the second differs by one or more carbon atoms in the side chain, a distortion of the elimination curve should reveal the fact.

A fuller description of the work will be published with acknowledgments to those who are contributing.

Intermolecular Forces and O—H Absorption Bands in Alcohols at 3μ

THE liquid aliphatic alcohols show in the region of 3 μ two C–H bands, 2870–2890 cm.$^{-1}$ and 2950–2970 cm.$^{-1}$, and a very large and intense band at about 3350 cm.$^{-1}$, which is generally attributed to a fundamental O–H vibration. If we dilute to a very small concentration, we observe for ethyl alcohol in carbon tetrachloride that, at normal temperature, in passing from a concentration of 3·33 mol/lit. to 0·005 mol/lit. and keeping the product concentration by thickness constant, the C–H bands retain their intensity, whereas the large O–H band, which absorbed 90 per cent, has disappeared completely at a concentration of 0·02 mol/lit. A new narrow and well-defined band appears then at 3640 cm.$^{-1}$, and its intensity grows with dilution. The molar extinction coefficient passes from 4, for a concentration 0·05 mol/lit., to 15 for a concentration 0·005, instead of remaining constant. The results for alcohol in carbon disulphide are in complete agreement with those mentioned above.

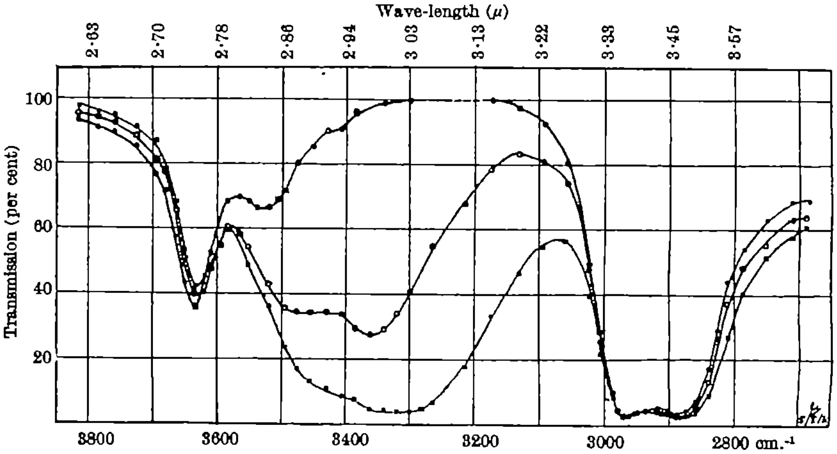

FIG. 1. Absorption of a 5 mm. layer of ethyl alcohol (0 1 mol/lit.) in carbon tetrachloride Bottom curve, at 0° C; middle curve, at 20° C.; top curve, at 70° C.

In our opinion, the band at 3640 cm.$^{-1}$ corresponds to the O–H vibration in the isolated alcohol molecule. With dilution the relative number of monomolecules grows, and this explains the increase in intensity of the band. This result is in agreement with the polarization measurements of C. P. Smyth, continued by K. L. Wolf, as well as his measurements of heat of mixing[1].

The large band which disappears with dilution is, on the contrary, due to intermolecular actions, for example, the hydrogen atom of one molecule vibrating with the oxygen atom belonging to another one (hydrogen bond, as interpreted by Sidgwick[2]).

Temperature effect measurements confirm our opinion. Fig. 1 shows that at 0° the O–H monomolecular band at 3640 cm.$^{-1}$ absorbs 56 per cent and the large band at 3350 cm.$^{-1}$ showing the influence of intermolecular forces absorbs 96 per cent. If we raise the temperature to 70°, the intensity of the two C–H bands remains exactly the same, whereas the band at 3350 cm.$^{-1}$ only absorbs a small percentage, and the intensity of the O–H band of the monomolecules increases and absorbs 64 per cent. Similar measurements on solutions of methyl, butyl, amyl and heptyl alcohols confirm this result.

It seems possible that the large band at 3350 cm.$^{-1}$ can be decomposed into two bands corresponding to different molecular aggregations (polymers).

Ultra-violet Luminescence of Sodium Chloride

SINCE the fluorescence and phosphorescence of sodium chloride are extremely weak in the ultra-violet, there have been few investigations of them until now[1]. Our measurements were carried out by a very sensitive photon counter. Samples of clear sodium chloride crystals were exposed to X-rays of 50 kv. and then irradiated by visible light for periods of a few seconds. Investigating the radiations of such crystals with the photon counter, we found a distinct ultra-violet phosphorescence which is remarkably changed if the crystal is plastically deformed.

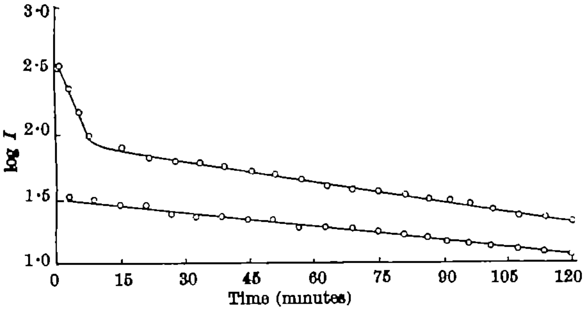

FIG. 1.

Fig. 1 shows the results. Curve I represents the decay of the intensity I of the ultra-violet phosphorescence of a sample of sodium chloride, which is perfectly free from deformation. Curve II shows the same for a crystal which was plastically deformed (bent) after irradiation with X-rays.

Comparing the two curves, it is evident that in the case of the bent crystal there are two monochromatic components in the ultra-violet phosphorescence of sodium chloride. One of these has a short half-life and is only present in deformed crystals while the other one (large half-life) is noticeable in all cases.

We have investigated the wave-length of these two components by means of a quartz monochromator. Component I has the wave-length $\lambda = 2350$ A.; while for component II, $\lambda = 2950$ A.

Comparing these results with the absorption measurements of Hilsch and Pohl[2] we find that component I ($\lambda = 2350$ A.) corresponds to a transition of the electron from the level of the F-centres (*Farb-Zentren*) to the ground-level, whereas component II ($\lambda = 2950$ A.) corresponds to a transition from the level of the F-centres to the level of the U-centres. It is interesting to find that the transition probability of component II is greatly dependent on the degree of deformation of the crystal.

Finally, we measured the excitation curve of the ultra-violet fluorescence of sodium chloride and we got more information about the origin of component II. The results of these investigations will be published later.

Ultra-violet Band Systems of the Emitters GeCl and GeBr

THE available data for the band systems of diatomic halides of Group IV(b) elements are fragmentary and give conflicting indications of the nature of the ground states, for which either $^2\Sigma$ or $^2\Pi$ is theoretically possible, and the latter has been regarded as more probable[1]. We have recently made observations of band systems of GeCl and GeBr, which seem to clarify the situation considerably.

Through the kindness of Sir Gilbert Morgan and Dr. G. R. Davies, we have been able to use a quantity of their germanium and germanium dioxide for the preparation of the tetrachloride and tetrabromide. Heavy-current tube-discharges through the vapours of these compounds develop the desired band systems with sufficient intensity to be photographed in a quartz Littrow spectrograph (Hilger's E 1). Each system consists of bands degraded towards shorter wave-lengths, the band-heads being represented approximately by:

$$\text{GeCl}: \nu = \left\{\begin{matrix}33{,}992\cdot2\\33{,}017\cdot2\end{matrix}\right\} + (526\cdot6\,u' - 0\cdot3\,u'^2) - (408\cdot4\,u'' - 1\cdot6\,u''^2)$$

$$\text{GeBr}: \nu = \left\{\begin{matrix}33{,}413\cdot4\\32{,}263\cdot4\end{matrix}\right\} + (388\cdot7\,u' - 0\cdot7\,u'^2) - (296\cdot6\,u'' - 0\cdot9\,u''^2)$$

where $u' = v' + \frac{1}{2}$ and $u'' = v'' + \frac{1}{2}$.

The observed electronic separation in germanium chloride is, as would be expected, intermediate between those in the lowest states of SiCl[2] and SnCl[3,4] and smaller than that in GeBr. Analogy suggests that these two separations of 975 cm.$^{-1}$ and 1150 cm.$^{-1}$ occur in the lower (presumably the ground) states of GeCl and GeBr. The first of these emitters has the same number of electrons and nearly the same mass as SiBr, the lower electronic state of which is apparently single[5], while the second stands in the same relation to SnCl, the lowest state of which is known[4] to be $^2\Pi$. For each of these iso-electronic pairs certain similarities in the results of analysis of the band systems are to be expected, and are, in fact, observed, except in regard to the lack of electronic doubling in SiBr.

A possible explanation of the apparent anomaly in the lower state of SiBr may lie in the fact that the electronic separation to be expected is of the order 400–450 cm.$^{-1}$, which is rather near the separations of the vibrational levels, $424\cdot6u'' - 1\cdot3u''^2$, and may thus be difficult to recognize; and if it happened to lie between, say, 420 and 425 cm.$^{-1}$, it might well pass entirely unnoticed in the analysis of the band system with the dispersion hitherto employed. A study of the intensities of the bands seems to support this suggested explanation. The further apparently anomalous case of the lead halides[6,7] has already been discussed.

1. Electronic energy ν_e of upper state

	F	Cl	Br
Si	34,639	34,103	33,570
Ge	—	33,992	33,413
Sn	—	33,582	—
Pb	32,565	21,867	20,884

2. Electronic interval $\delta\nu_e$ in lower state

	F	Cl	Br
Si	161	208	—
Ge	—	975	1,150
Sn	—	2,360	—
Pb	—	—	—

3. Value of ω_e'

	F	Cl	Br
Si	1011·2	(698·7)	578·3
Ge	—	526·6	383·7
Sn	—	432·5	—
Pb	397·8	228·6	152·5

4. Value of ω_e''

	F	Cl	Br
Si	856·7	535·4	424·6
Ge	—	408·4	296·6
Sn	—	353·5	—
Pb	506·9	304·2	207·5

The above tables of data for this *MX* group show that the electronic separations $\delta\nu_e$ in the lower states, the electronic energies ν_e of corresponding upper states, and the vibrational frequencies ω_e' and ω_e'', all have the expected trends as the mass of M or X is increased, namely, a slight decrease of ν_e, an increase in $\delta\nu_e$, and decreases of ω_e' and ω_e''.

[7] F. Morgan, *Phys. Rev*, **49**, 47 (1936).

SINCE writing the foregoing letter, we have obtained evidence for the correctness of the explanation there suggested of the apparent lack of electronic doubling in the lower state of SiBr. Some time ago we obtained spectrograms in the Hilger *E* 1 instrument of a heavy-current tube-discharge through $SiBr_4$ vapour in order to see whether an alternative to Miescher's arrangement (*loc. cit.*) of the SiBr band-system was possible. Miescher's analysis was confirmed, but several of the band-heads were found to have a companion, about 4 cm.$^{-1}$ towards the red, which he did not record. The additional heads could not be included in Miescher's analysis or be explained as a Br isotope effect or be ignored. It now appears that they constitute a fragment (including 1 → 0, 0 → 0 and 0 → 1 band-heads) of the expected sub-system, and are accounted for by the smaller of the two independent coefficients in the following provisional formula for the whole system,

$$\nu = \begin{Bmatrix} 33{,}571\cdot 2 \\ 33{,}147\cdot 2 \end{Bmatrix} + (574\cdot 8u' - 4\cdot 0u'^2) - (424\cdot 7u'' - 1\cdot 4u''^2).$$

Apart from the inclusion of this smaller coefficient, the formula differs only slightly from Miescher's. Comparison with other band systems of the same group of emitters suggests that the electronic separation of 424 cm.$^{-1}$ now observed belongs to the lower ($^2\Pi$) state. Thus the anomaly to which we referred disappears.

Geometrical Constitution of Silicichloroform

POLARIZATION measurements of Raman lines of chloroform made by Cabannes[1] and discussed by him show that this molecule has not a perfect pyramidal symmetry. On the other hand, recent electron diffraction measurements discussed by Degard[2] are not able to fix with precision the position of the carbon atom in the chloroform molecule. Is it so, also, for silicichloroform ? To measure the state of polarization of the Raman lines of silicichloroform we employed the same method as that used by Cabannes. Optical parts of the instrument were made by the Société Belge d'Optique ; we have to thank M. Cailler, director of that company, for his kindness. The spectrograph used was a Hilger *E* 443. The following results were obtained :

$HCCl_3$	ω :	261	758	365	667	1218	3019
	ϱ :	0·7	0·68	0·22	0·06	6/7	0·32
$HSiCl_3$	ω :	179	587	250	489	799	2258
	ϱ :	0·846	0·74	0·29	0·056	0·79	0·20

It appears that conclusions similar to those for chloroform apply in the case of silicichloroform. The number of Raman lines is in favour of a pyramidal structure of $SiCl_3$. Their classification compared with that of chloroform is given in the above table. The value of 0·846 and 0·740 given for 179 and 587 are greater than 0·7 and 0·68 for chloroform, showing that the $SiCl_3$ pyramid is more regular than the CCl_3 pyramid.

We have also examined silicichloroform by electron diffraction methods, using for this purpose a de Laszlo apparatus. We obtained the following results :

$$\text{Si–Cl} = 2\cdot 05\ \text{A.} \quad \text{Cl–Cl} = 3\cdot 39\ \text{A.}$$

The distance Cl–Cl is not quite in agreement with that given by L. O. Brockway[3], but agrees well with some preliminary unpublished results obtained by the X-ray diffraction method which have been very kindly communicated to us by Pirenne in Liège. Both distances, Si–Cl and Cl–Cl, show that $SiCl_3$ must be a pyramid of height 0·65 A. and angle ClSiCl = 113° 30′.

Natural Selection

IN NATURE of October 17, there appears a letter by my friend Prof. Hale Carpenter entitled "Insect Coloration and Natural Selection", written in answer to one of mine on natural selection published in these columns a few weeks previously. I maintained that "natural selection" was an "explanation" neither of mimicry nor of any other biological phenomenon whatever. Prof. Carpenter does not meet my arguments, but merely reiterates his conviction that natural selection is the only explanation which will enable us to account for mimicry.

I wish to restate my main argument more concisely and particularly. 'Natural selection', that is, the survival of the few amongst the many born, is a mere truism which we all accept. But 'natural selection' *as an explanation of evolution* implies the constant occurrence of random heritable variations in all directions, so that any conceivable demand of the environment may be met by some variation. In a word, it is the doctrine of evolution by pure chance.

Do such random heritable variations really occur ? The experimental evidence entirely negatives this assumption. Ordinary fluctuating variations which can be graphically represented on a 'curve of error' are certainly not inherited. This has been proved by the 'pure line investigations' carried out by Johannsen on the bean, by Agar on the crustacean *Simocephalus* and by Jennings on the protozoan *Paramecium.* When the same results are reached by the examination of a flowering plant, a crustacean and a protist—organisms belonging to as diverse groups of living things as could be well imagined—it is surely just to conclude that these results express a universal law.

However, heritable deviations from the normal, formerly known as 'sports' but now as 'mutations', undoubtedly do crop up in the farmyard and in the cultivated field and garden. Can they furnish the material on which 'natural selection' can work so as to produce evolution ? The answer from experiment is again decidedly no ! Mutations have been produced by subjecting the eggs of insects to heat and to X-rays. These agents kill a large number of eggs; some survive unhurt and a few are half-killed and give rise to mutations. Mohr, the greatest European authority on *Drosophila* work, arranged all the mutations observed in this insect on a scale which he compared to the colours of the spectrum: the slightest were at the red end and the most pronounced at the violet end. All produced a loss of viability and vigour which was proportionate to the extent of the mutation. That such weakened specimens could ever give rise to a new natural race is utterly incredible.

I am aware that desperate attempts have been made by the apostles of chance to save the situation. It has been asserted that mutations may be very small, and that there is no proof that such mutations affect the health of the individual. Hence they may be even beneficial. This seems to one to be equivalent to saying that a pimple is of a totally different nature from a boil because it does not noticeably raise the temperature. The best disproof of the theory that any mutation can be beneficial and even give rise to a racial character is the well-known fact of reversion. When any mutant is returned to wild natural conditions and *survives*, it goes back to the original wild type. A beautiful example of this reversion was furnished me by a very distinguished botanical colleague. The common flowering plant *Calceolaria* is a native of Mexico and produces bright yellow flowers. As all are aware, gorgeously coloured garden varieties of this flower are cultivated. My friend in visiting the hill stations of India saw these varieties in the gardens of the residents there: the plants had in many cases escaped on to the hillsides and, in every case, had reverted to the wild *Calceolaria* and produced yellow flowers.

Thus the 'selectionist' is shut in between the jaws of a vice and deprived of the material for evolution. The only escape is by means of the heritability of long-continued acquired habit, which has now been amply demonstrated. That evolution, so far as structure is concerned, is an infinitely slow process was shown by Woltereck, when he demonstrated that 16,000 years has been required to convert the small Crustacea inhabiting the post-glacial lakes of Bavaria—not into new species—but into new varieties.

When, therefore, Prof. Carpenter asks how I account for the colours and shapes of the insect mimics, I reply that I do not attempt such a futile task in the present state of our knowledge. Only when we know in infinite detail the steps of the process by which the mimicking pattern has been produced can the task be profitably attempted. If Prof. Carpenter really wishes to know how the evolution of colour proceeded, let him go to the museum at Tring. There he will see trays containing hundreds of insects of the *same* species; different trays are taken from adjoining localities, and as one passes along them one sees the gradual change of colour with locality, until if one compares the end terms in the series one seems to be looking at two different species.

I shall conclude by giving one charming instance of "evolution by natural selection" supplied me by a friend and colleague on the staff of the Plymouth Marine Biological Station. The angler fish, as all marine biologists know, fishes for its prey by a flexible rod with a bait at the end. The rod is one of the dorsal spines: the bait a bit of glittering skin. But the angler is not an indiscriminate devourer of all that comes its way. When it sees a sea-bream approaching, it lays back its rod into a groove and makes no attempt to catch the fish, which has a row of hard dorsal spines and is a most unpleasant morsel to swallow. But when the angler sees a pollack, it erects the rod and dangles the bait so as to lure the fish within reach of its powerful jaws—for the pollack is a soft-spined fish. So we see how by a series of "beneficent mutations" hard spines have been gradually acquired by the sea-bream in order to protect it against the angler.

The only difficulties about this explanation are: (1) that hard spines are an original and primitive characteristic of teleostean fish and date back to the Mesozoic epoch, and are also characteristic of many families that never have any opportunity of coming into contact with an angler; (2) that the unprotected pollack are one of the most abundant species of fish, which exist and swarm in countless millions in all northern seas and are quite indifferent to the toll levied on their numbers by the angler.

Selectionist theories tested in the field wear a very different aspect from that which they exhibit in the study.

Regeneration in Arachnida

IN view of the remarks made by Mr. T. H. Savory[1] on the failure of a harvestman (Opiliones) and of *Pholcus Phalangioides* (a spider) to regenerate lost limbs, the following observations appear relevant.

In 1932 and 1933 it was found that four males of the spider *Theridion ovatum* Cl. (*Phyllonethis lineata*) failed to regenerate front legs removed one and two days after the penultimate cast. Fourteen males failed to regenerate first legs and thirteen to regenerate lost palpi. In one male there was no regeneration at all of a palp lost in the anti-penultimate instar. With *Linyphia triangularis* Cl., four males failed to regenerate front legs and in one case second legs, but in only three cases were the results significant (the amputations being then made thirteen and fourteen days before the last moult). Eight males failed to regenerate palpi the femora of which were severed; two cases were significant. The palpi of two males were partly regenerated after amputation of the joint between femur and tibia; one specimen found without a palp in the penultimate instar developed an incomplete one after the last moult. These were all the experiments made.

Cases of non-regeneration in *Dolomedes* are recorded by Bonnet[2], who deals with the whole question of regeneration in great detail and points out that a limb is regenerated as a rule if the interval between the amputation and the following moult is not less than three quarters of the time separating the moults.

Savory states that failure to regenerate a leg "might be related to the contrast between the length of the limbs and the shortness of the cephalothorax, within which it would be impossible to develop a leg long enough to be useful when exposed by ecdysis". This would imply that the new limb is developed within the cephalothorax, whereas it was shown first by Blackwall[3] and most recently and conclusively by Bonnet[2] that the new limb is formed spirally within the remaining part of the old one, even if the coxa alone remains.

It is scarcely likely therefore that the relative size of cephalothorax and legs has much to do with the problem. Moreover the palpi which, especially in the male spider, are of the greatest use, are sometimes not replaced, and they are comparatively small compared with the cephalothorax.

The Common Stick Insect

Since 1910, we have bred a continuous supply of the common stick insect (*Carausius*). These are lodged in a glass rectangular case 18½ in. × 9 in. × 15½ in. fitted with a movable glass front. Two glass vases holding ivy leaves in water furnish food and moisture for the insects. The debris is removed from the case once a fortnight, when fresh food and water are supplied. The eggs which lie about in the debris are picked out and placed in a small box which is kept inside the cage, so that they are subject to the same temperature and moisture conditions as the adults. There is always a mixed population of insects in the cage, ranging from newly hatched individuals to one year old adults.

We found that during the very sunny months of the year, the excessive transpiration of the ivy leaves made the air in the chamber too damp and so favoured the growth of mould over debris and elsewhere. To afford more efficient ventilation, we removed the glass sliding door and replaced this by a piece of cotton veiling of 1/16 in. hexagonal mesh. This was not new material. It had been washed several times, but it was quite strong. The adults particularly made their way to the netting and clung to it.

On account of the exigencies of vacation in 1936, the stick insects had been left unattended for three weeks. At the end of that time, all the ivy had been consumed. Small holes were noted in the net when the food supplies were renewed. The netting was replaced. At the end of another three weeks, the food supplies were all eaten and the netting had been attacked more vigorously. On this occasion several holes were ½ in. in diameter, and the smaller holes ¼ in. in diameter were evenly disposed all over its area. Judging by the absence of fibrous material around these holes, it seems certain that the cellulose is eaten by the insects. (A specimen of the netting was kindly examined in the Textile Research Laboratory of Leeds and pronounced to be cellulose.) This experiment slightly modified was repeated, one isolated adult making a hole of diameter 1 in. The insects make no attempt to escape by these holes, whether or no because of anatomical impossibility we have not been able to decide.

Younger adults were then used for the experiment. They similarly attacked the material greedily.

Lastly, a piece of twill calico well washed was placed in front of the cage and the insects were given sufficient food. This also has been attacked, though as one would expect, the holes are smaller and are not produced so quickly.

Raman Effect in Absolute Perchloric Acid

According to recent views, hundred per cent liquid oxacids are pseudo-homogeneous substances, composed of covalent hydroxyl compounds partly associated by means of the unsaturated hydroxyl group. In a few cases, some of the acid molecules may act as proton acceptors, thus forming an acidium salt, accounting for the electroconductivity of the pure acid.

Thus in the case of pure perchloric acid, we have following equlibria :

$$2\mathrm{HOClO_3} \rightleftarrows (\mathrm{HOClO_3})_2 \rightleftarrows [(\mathrm{HO})_2\mathrm{ClO_2}]^+ + [\mathrm{ClO_4}]^-$$

If a little water be added, there is competition for protons between $HOClO_3$ and H_2O molecules, with water being successful, since it is a stronger acceptor than perchloric acid. In this way, a solid hydronium salt may be formed, the X-ray diffraction pattern of which is, according to Volmer[1], the same as that of ammonium perchlorate. If further water be added, it is used for the hydration of the hydronium and perchloric ions.

$$\underbrace{\mathrm{HOClO_3} + \mathrm{H_2O}}_{\mathrm{H}^+} \rightarrow [\mathrm{H_3O}]^+[\mathrm{ClO_4}]^- \rightarrow [\mathrm{H(H_2O)}_x]^+[\mathrm{ClO_4(H_2O)}_y]^-$$

If this be true, the Raman spectrum of absolute perchloric acid must be quite different from that of perchloric acid in solution, and some information regarding the nature of the molecules and ions present may be obtained.

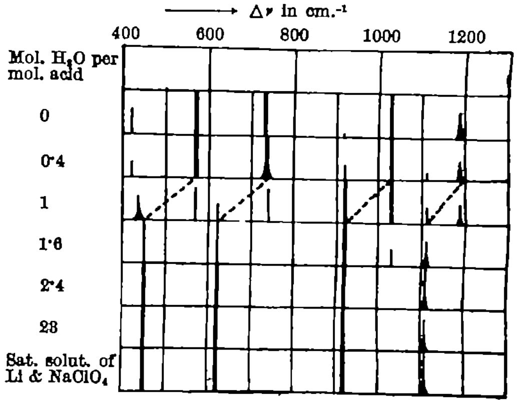

Fig. 1.

Fig. 1 represents the results of our examination of perchloric acid solutions : molten monohydrate (at 50° C.), pure perchloric acid and saturated solutions of lithium and sodium perchlorates. The figures clearly show that perchloric acid solutions up to 70 per cent (2·4 mols. of water) produce exactly the same Raman lines ($\Delta\nu$ = 450, 620, 922, 1110 cm.$^{-1}$) as the salt solutions. The nature of the radical corresponding to these lines, which is the ClO_4^- ion, is consequently identical in both cases. When the concentration of perchloric acid becomes higher, all these lines diminish in intensity, while other new lines appear and increase in intensity. The spectrum of pure perchloric acid shows four main lines of frequency number 570, 730, 1026, 1190 cm.$^{-1}$, which have the same aspect and relative intensity as the corresponding lines of the ClO_4^- ion. Therefore, the structure of the perchloric acid molecule cannot be very different from that of the perchloric ion, being a point-symmetrical one; only the binding forces are greater. Furthermore, the fact that the strongest line of the perchloric ion ($\Delta\nu = 922$ cm.$^{-1}$) persists even in the pure acid, suggests that the formation of an acidium salt is real, though the lines due to its cation are failing. In fact, the addition of a proton to the acid molecule changes but little the vibrating masses, and probably causes only a slight shift of some of the lines towards lower frequencies. The broadening and shifting of line 730 cm.$^{-1}$ is perhaps due to the disappearance of the complex cation.

In connexion with the presence of an acidium salt, the associated molecules give rise to a vibration of low frequency ($\Delta\nu = 422$ cm.$^{-1}$). Owing to the weakness of this line and to the great fluidity of pure perchloric acid, this association cannot be very strong. In presence of water, the association diminishes, while the acidium salt disappears. When both an acid and a water molecule are present, the following molecules and ions exist side by side:

$$(HOClO_3)_2,\ HOClO_3,\ ClO_4^-.$$

Consequently, the hydronium salt is not a homogeneous one. Even in solutions containing 1·6 H_2O molecules, there exist undissociated acid molecules. We think that this may be the case in solutions of perchloric acid of concentration higher than 72·3 per cent (2 mols. H_2O). The acid of constant boiling point would have therefore the composition $[H(H_2O)_2]^+[ClO_4]^-$.

Points from Foregoing Letters

EXPERIMENTS by Prof. A. I. Virtanen show that legume nodules excrete more nitrogen compounds in the presence of kaolin, sand or soil than in water cultures. The excretion is helped by the presence of other plants (barley, potatoes). The author considers that the distribution of the nitrogen compounds between the nodule and the external medium is determined by an equilibrium, and the removal of the compounds, either by adsorption on sand, etc., or their utilization by other plants, leads to further secretion. In certain circumstances, potatoes when grown with peas actually acquire more nitrogen compounds than the peas themselves.

Identification of vitamins present in oils by means of special vacuum ('molecular') distillation is reported by Dr. K. Hickman. The amount of vitamin distilled with the oil over a range of temperature follows a typical 'elimination' curve, and the presence of different vitamins or vitamin compounds can be detected by irregularities in the curve. With this method the author finds that vitamin A in cod liver and halibut liver oils exists almost entirely in the form of esters, while vitamin D (in cod liver oil) occurs partly free and partly as a mixture of esters.

Prof. J. Errera and Dr. P. Mollet bring forward evidence to show that the large absorption band at about 3350 cm.$^{-1}$ in liquid alcohols is not the fundamental O–H band of the isolated molecule, for it is strongly affected by intermolecular forces. The O–H band of the monomolecule appears in dilute solutions or at higher temperature at 3640 cm.$^{-1}$.

Curves showing the ultra-violet luminescence of crystals of sodium chloride, normal and deformed, which were exposed to X-rays and then irradiated by visible light, are submitted by Prof. M. Schein and M. L. Katz. The normal crystals emit ultra-violet light of wave-length 2350 A., while the deformed crystals give, in addition, ultra-violet light of wave-length 2950 A., but of shorter duration. The measurements were carried out by means of photon counters.

L. A. Bashford, Prof. H. V. A. Briscoe and Dr. W. Jevons announce the discovery and analysis of an ultra-violet band system of both GeCl and GeBr, and find that the lower (presumably the ground) states are electronic doublets (probably $^2\Pi$), separations of which are of the orders to be expected from analogy with diatomic halides of other Group IV(b) elements. A possible explanation of the non-detection of a similar doubling in the lower state of SiBr is suggested. In a subsequent letter the authors state that they have observed this doubling in new SiBr spectrograms.

Measurements of the polarization of the Raman spectrum lines of silicichloroform, $HSiCl_3$, carried out by Prof. M. de Hemptinne and J. Wouters, indicate that the pyramidal arrangement of the $SiCl_3$ group of atoms, though not perfect, is more regular than that of the CCl_3 group in chloroform.

Reverting to the controversy around natural selection, Prof. E. W. MacBride states that it cannot explain evolution because ordinary random variations are not inheritable. Further, he considers that mutations can never be beneficial, but lead to loss of viability and consequently cannot produce new races. Prof. MacBride sees the solution of the evolution problem in the heritability of long-continued acquired habit, which, he states, has been amply demonstrated.

G. H. Locket supplies additional instances of spiders failing to regenerate lost limbs and feelers. He refers to opinions of previous investigators concerning the factors which may influence regeneration or the lack of it.

Sister Carmela Hayes reports observations on the common stick insect (*Carausius*) which show that these insects eat cellulose (in the form of calico) even when sufficient food, in the form of ivy leaves, is available.

Diagrams showing the Raman spectra of perchloric acid, pure and in various aqueous dilutions, also of saturated solutions of lithium and sodium perchlorates, are given by R. Fonteyne. From the identity of the lines produced by the salt solutions and solutions of the free acid up to seventy per cent concentration, and their similarity with those of pure perchloric acid, the author concludes that the structure of the perchloric acid molecule cannot be very different from that of the perchloric ion. He considers that when both acid and water are present, then $(HOClO_3)_2$, $HOClO_3$ and ClO_4^- exist side by side.

Research Items

South Indian Blood Groups

A STUDY of the blood groups of a jungle tribe (Pre-Dravidian), the Panīyans of Wynad, has been made by Mr. A. Aiyappan of the Government Museum, Madras (*Man*, November). This tribe was selected as being more isolated and in a purer state than most other Pre-Dravidians. No great degree of admixture with them has taken place, owing to the sexual jealousy of the tribal code. Until recently they were very wild. The Australians, Veddahs and Panīyans, notwithstanding close resemblances, are differentiated by several anatomical characters, especially of the face. The Panīyan is infantile and prognathous, whereas the Veddah is orthognathous; and the supraciliary ridges of the Panīyan are less prominent than in either Australian or Veddah. Nothing is known of the blood-typing of the Veddahs, and comparison is therefore restricted to the Australians. Two hundred and fifty Panīyans from three different settlements were tested. The following results were obtained: *O*, 20 per cent; *A*, 62·4 per cent; *B*, 7·6 per cent; *AB*, 10 per cent. The Australian figures are: *O*, 57 per cent; *A*, 38·5 per cent; *B*, 3 per cent; and *AB*, 1·5 per cent. Thus though there is no close resemblance between the two sets of data, they agree in having a low percentage of *B*. Von Eickstedt makes an interesting suggestion that the Pre-Dravidians may be regarded as the Palæ-Europid type, and this the blood grouping supports. In a correlation table the Panīyans will be placed very near the Lapps and other peoples of western Europe. The Panīyans show a much lower percentage of *O* than the Australians; but Cleland, typing a sample of central Australians, found 38·1 per cent *O* and 61·9 per cent *A*. If further research confirmed this bigger series, we should be able to say that serologically the Australians and Panīyans are closely linked.

Pawnee Archæology

THE Pawnee Indians of Nebraska and Kansas, who formerly occupied permanent villages in the Platte and Loup Valleys and on the Republican in the present State of Nebraska, have been known to the white man since 1541, when they may have been visited by Coronado, and certainly since 1673, when Marquette, the French Jesuit, noted them in his map at some distance north of the Kansa. They were the most numerous and powerful of the tribes constituting the Caddoan linguistic stock, and one of the most important in the Plains area. The tribal organization consisted of four endogamous bands, each functioning as an independent unit, but with the principal chief of the 'Grand' band acting as spokesman for the whole on occasion. One band, the Skidi or "Wolf" Pawnee, seems to have had a different ancestry, or to have been an earlier offshoot from the parent stock, as this branch was less closely bound to the others. A persistent tradition places their original habitat in the south or south-west, while another associates them with stone-built houses, although in fact there is no evidence of a Pueblo connexion. Archæological remains, surprisingly rich and numerous, have been discovered at many of the village sites formerly occupied by the tribe. These, with the documentary history and traditions of the tribe, have been made the subject of detailed examination by Mr. Waldo Rudolph Wedel (Bull. 112, Bureau Amer. Ethnol.). The conclusion at which he arrives is that the material traits in Pawnee culture are drawn in large measure from the east and south-east. They formerly constituted part of the south-east Woodland culture area in its more western peripheral phase, retaining and disseminating many of the traits they acquired throughout the period of their northern residence, until Plains culture disappeared before the European contact.

Treatment of Cancer with an Enzyme Solution

BULLETINS will be issued from time to time by the Hendry-Connell Research Foundation, which will unite in one publication the laboratory and clinical aspects of medical research pursued there. In *Bulletin* No. 1, August, 1936 (Kingston, Ont., Canada), the results to date of the treatment of cases of cancer with a preparation named 'Ensol' are detailed. This is a solution of proteolytic enzymes obtained by digesting malignant tissue, removed at operation, with a pure culture of an anærobic bacillus, *C. histolyticum*. After six days growth, the mixture is centrifuged and filtered through a Berkefeld filter candle to remove organisms, the filtrate obtained constituting the 'Ensol'. Experimentally, when placed upon carcinoma tissue, it produces rapid lysis or solution of the cancer cells. This preparation is injected into the patient, and appears to have no harmful effect. Dr. H. C. Connell contributes papers on the clinical results of 'Ensol' therapy. Patients to the number of 382—cases of inoperable cancer or who refused surgical interference—were treated with 'Ensol' alone. Of these, 180 (47 per cent) ultimately died, 106 (27·7 per cent) appeared to be permanently benefited, and of the remainder most were relieved, and only 13 showed no benefit. Other papers in the *Bulletin* deal with the reactions of 'Ensol', and with the cultural characters of *Clostridium histolyticum*.

The Pine Shoot Moth

FORESTRY COMMISSION BULLETIN No. 16 (H.M. Stationery Office. 1*s*. net) on the pine shoot moth (*Evetria buoliana*) in England is of special significance in connexion with afforestation schemes where conifers are involved. The authors, the late Mr. C. C. Brooks and Mr. J. M. B. Brown, discuss the life-history and possible means of circumventing the ravages of this insect. During the past few years, the Forestry Commission's plantations in East Anglia have suffered severely from its ravages. An investigation of the pest was begun in August 1928 at the Imperial Forestry Institute, Oxford, most of the data being obtained from the Brecklands area. The larva destroys the leading buds or shoots, and unequal growth, or distortion, of the trees is a common effect of its activities. An encouraging factor in the situation is that the Corsican pine suffers notably less from this insect than the Scots pine, and its planting, under certain conditions, is advocated.

Helisoma corpulentum and its Relatives in Canada

THE freshwater mollusc *Planorbis corpulentus* Say, now known as *Helisoma*, is the subject of an extensive monograph by F. C. Baker (Canada Department of Mines, National Museum of Canada, Bulletin No. 79, Biological Series No. 21, 1936. Contributions from the Museum of Natural History, University of Illinois, No. 75). By studying a large number of specimens, it has been possible to clear up a great deal of confusion with regard to this mollusc, and it is shown that the species is a composite one embracing several varieties and at least one additional species, which have been previously referred to *corpulentum*. The large snails of the genus *Helisoma* divide into two well-defined groups, *corpulentum* and *trivolvis*, around which several species and races arrange themselves. In a previous paper (*Ecology*, 11, 469; 1930) the author directed attention to the significant geographical distribution of certain species of freshwater molluscs in relation to the moraines of the last glacial invasion, the Wisconsin, when the country was greatly changed, many new species being evolved. The study of the helisomas of the *corpulentum-trivolvis* groups illustrates this well, and it is suggested that the parent stock of the large helisomas is probably the widely distributed *H. trivolvis* of the central and eastern part of the United States.

Bacterial Flora of Blow-fly Larvæ

WE have received from Dr. N. Balzam, ul. Nowolipki Nr. 21, m. 5, Warsaw, a short, preliminary communication on this subject. It appears that the larvæ of *Calliphora erythrocephala*, and also the young and older pupæ, contain numbers of bacteria—it is stated about two million per individual. In the course of metamorphosis they disappear from the larval alimentary canal and pass to the tissues of the nymph where they become localized, since they do not occur in the hæmolymph or the newly formed gut. On the last day of pupal development, rapid destruction of the bacteria takes place, and in the great majority of flies none is found several hours after hatching. Dr. Balzam supposes that a cellular or phagocytic activity explains the passage of the bacteria from the larval gut to the tissues of the nymph and their absence from the hæmolymph. The final result is that, owing to complete 'auto-sterilization', the young flies are free from bacteria, and, therefore, do not disseminate pathogenic germs derived from the larvæ. A full account of the work, it is stated, will appear in a coming issue of the *Annales de l'Institut Pasteur*.

Type Cultures of Micro-organisms

THE Medical Research Council has issued a fourth edition of the Catalogue of the National Collection of Type Cultures, maintained at the Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1. (*Special Rep. Series*, No. 214. London: H.M. Stationery Office. 2*s*. 6*d*. net). Five years have elapsed since the publication of the third edition of the Catalogue, and during this period a large number of species of bacteria and micro-fungi have been added to the Collection. In the present edition, the generic name *Bacillus* has been restricted to the spore-bearing rods, ærobic and anærobic. Most of the non-sporing rod-forms are listed under *Bacterium* except where well-recognized generic names are in common use, for example, the diphtheroids (*Corynebacterium*) and the organisms of undulant and abortus fevers (*Brucella*). The typhoid and para-typhoid bacilli and food-poisoning organisms are, however, placed under *Salmonella*, and the dysentery bacilli under *Bacterium*. It is pointed out that nomenclature is in a state of flux, and is now being considered by two or three committees. In respect of both bacteria and fungi, a number of synonyms is given for the convenience of those more familiar with the older systems of nomenclature. In addition to bacteria, yeasts, micro-fungi and *Actinomyces*, several strains of bacteriophage, and a few Protozoa and viruses are also stocked. Cultures may be obtained for a small fee on application to the Curator. In order to increase the services that may be rendered to microbiologists, it is requested that cultures be forwarded to the Curator, not only those of newly isolated species, but also fresh examples of types at present conserved in the Collection.

Role of Silicon in the Plant

A SERIES of papers upon this subject by A. Sreenivasan have recently appeared (*Proc. Indian Acad. Sci.*, 1, 2 and 3). The inquiry appears to have arisen out of the fact that the rice plant, which accumulates exceptionally large quantities of silicon in its ash, grows so satisfactorily under swamp conditions. This raised the question whether swamp conditions are particularly favourable for silicate supply and also raised anew the question as to the role of silicon in the plant. An extensive series of experiments with rice, grown both in swamp and dry soil conditions, showed that whilst both phosphate and silicate manurial treatments increase yield, silicate is particularly useful in raising the yield from manured and soils to practically the same level as that in swamp soils. The conclusion is reached that the swamp conditions, therefore, are suited to the rice plants because thus large amounts of silica are supplied to the plant which would otherwise remain unavailable. The role of silicon still remains obscure; the author points out that its accumulation may be a secondary result of growth in swamp conditions which are otherwise favourable to the plant, for example, on account of the resultant presentation of nitrogen to the root system in ammoniacal form. The mode of entry of silicon into the plant also remains obscure; but this detailed examination has cleared up many points as to the behaviour of silicates in the soil, to which they contribute both an alkali and a silicate gel, and as to their significance in the manurial treatment of the rice crop.

Gravity Measurements in Sweden

PART 2 of vol. 25 of *Archives of Mathematics, Astronomy and Physics* of the Swedish Academy of Sciences contains two communications which show that progress is being made in the determination of the geophysics of Sweden. The first, by Drs. G. Ising and T. Eeg-Olofsson, gives an account of the measurements of the gravitational acceleration in the extreme south of the country by a modified form of the quartz fibre torsion method used by Threlfall in Sydney, forty years ago. The horizontal quartz fibre is supported at its ends by the lower forked end of a rod suspended like a pendulum from a support at its upper end. The centre of the fibre has attached to it one end of a small rod of quartz 1·6 cm. long, and the fibre is twisted until the rod is nearly horizontal, when a very small change of gravity makes a considerable change in the position of the free end observed by microscope. The torsional constant of the fibre is kept constant by surrounding the apparatus with ice. The results show that the variations of gravity with latitude and height are nearly normal over chalk districts, but over the higher districts of Cambrian and Silurian rocks gravity exceeds the normal value by 0·04 or 0·05 C.G.S. units. The second communication, by Dr. G. S. Ljungdahl, on the magnetic anomalies, shows that they are much greater in Sweden than in France and that over the Baltic depression of 400 metres south-east of the island of Uto, the normal deviation of the compass to the west (about 5°) is reduced by 1°. The author hopes, as more results for gravity throughout Sweden become available, to trace further relations between regional anomalies of gravitation and the earth's magnetism.

Sound Insulation by Double Partitions

J. E. R. CONSTABLE, working in the National Physical Laboratory, has investigated the effect of introducing absorbent materials into the air space between light double partitions (*Proc. Phys. Soc.*, 48, 690; 1936). Previous work had shown that the efficiency of a double partition for sound insulation was mainly dependent on the spacing between the panels. A calculation showed that the transmission would be considerably reduced by absorbing, inside the space between the panels, the sound which is reflected back and forth there. Experiments made by introducing acoustic felt into the space between double walls of thin iron or aluminium produced improvements in sound insulation which were in agreement with calculation and were of the order of 10 decibels.

Entropy of Deuterium Oxide

THE calorimetric entropy of ordinary water does not agree with entropies calculated from band spectrum and reaction data. An explanation recently given by Pauling assumes a random orientation of hydrogen bonds in the crystal. The entropy of deuterium oxide ('heavy water') shows a similar discrepancy (E. A. Long and J. D. Kemp, *J. Amer. Chem. Soc.*, 58, 1829; 1936). The specimen had a density of 1·10781, corresponding with 99·92 atomic per cent, and a melting point of 276·92° K. The latent heat of fusion is 1,501 gm. cal. per mol. The calorimetric entropy of the liquid at 298·1° K. is 17·27 E.U.; the value which should be used in thermodynamical calculations is 0·806 E.U. higher on the basis of Pauling's theory. From the measured heat capacities and the known heat of sublimation, the calorimetric entropy of D_2O gas at 273·1° K. is 45·89 U.E. at 1 atm. pressure. The value from spectroscopic data is 46·66 E.U., giving a discrepancy of 0·77 E.U. between calorimetric and spectroscopic values. This is in good agreement with the theoretical value of 0·806, which is evidence for the correctness of Pauling's theory.

Indium

THE metal indium, belonging to Group III of the Periodic Table, has been very scarce. It is found in small amounts in certain zinc blendes, in zinc carbonate minerals, and in various ores of iron (including chalcopyrite, $Cu_2Fe_2S_4$), manganese and tin. It has also been found with cadmium and has been detected in all specimens of metallic tin examined by two investigators. F. M. Brewer and E. Baker (*J. Chem. Soc.*, 1286; 1936) now report that two rare tin minerals, cylindrite and franckeite, sulphides of lead, antimony and tin, have an indium content (0·1–1·0 per cent) much larger than any source yet reported. These minerals are confined to the Bolivian tin belt, where argentiferous thiostannates are found. Indium was also found in some silver minerals not containing tin. The same authors in a second paper (p. 1290) describe methods for the extraction of indium from cylindrite, chalcopyrite and metallic tin. Indium is coprecipitated with stannous sulphide. Since the boiling point of indium chloride is much higher than that of stannic chloride, they can be separated by distillation. Details of other methods are given.

High-Frequency Modulation of Ultra-Short Waves

THE development of television transmissions on ultra-short waves has necessitated the study of methods of modulating carrier waves of a few metres in length with modulation frequencies of the order of one megacycle per second. The usual methods of amplitude modulation employed for sound broadcasting at moderate carrier frequencies are not satisfactory, owing to the undesirable frequency modulation and vision distortion which accompany their use. Messrs. S. S. Banerjee and B. N. Singh, of the Physics Department, Benares Hindu University state, in a communication addressed to the Editor that they have recently been studying the use of short parallel-wire transmission lines in the modulation of ultra-short waves (wave-lengths 4–5 metres) by high frequencies of 1·5–3 megacycles per second. From the general equations applicable to such transmission lines, it can be shown that amplitude modulation free from frequency modulation is obtained when the length of the line is an integral multiple of a quarter of the length of the carrier wave. This condition, which is fairly critical, has been verified experimentally by the above investigators with the aid of a modified Lecher wire system previously adopted by Banerjee (*Phil. Mag.*, 19, 787; 1935) in connexion with the measurement of the radiation resistance of transmission lines. At the high modulation frequency employed, the effects of the carrier wave and side bands are adequately separated on the Lecher wire system. The detailed results of these investigations will be published elsewhere shortly.

Colours of Globular Clusters

THE problem of the absorption of light in space with the consequent 'reddening' effect of great distances, has been investigated by Stebbins and Whitford (*Astrophys. J.*, 84, 132) through a study o globular clusters. They have used a photo-electric cell attached to the 100-inch telescope at Mount Wilson, and determined the colours of 68 clusters by means of the integrated light intensities of each cluster through filters transmitting light of effective wave-length 4340A. and 4670A. The colour excesses show a marked correlation with space absorption a deduced from the number of extra-galactic nebulæ in the field, and also with galactic latitude; being of course, redder near the galactic equator where th absorption is greatest. The absorption was not found to be uniform, and the greatest measured colour excess was + 0·82 mag., corresponding to a photographic space absorption of about 3 magnitudes One effect of this absorption is that distances inferred from apparent magnitudes in clusters must b divided by four. When this correction is made, the diameter of our galaxy is found to be about 30,000 parsecs, which is of the same order as that of th Andromeda nebula.

Education for Rural Life

A JOINT session of Sections L (Educational Science) and M (Agriculture) was held on September 15 at the British Association meeting at Blackpool to discuss "Education for Rural Life". Papers were read by three representatives of each section.

Sir John Russell emphasized that education in rural areas must develop on lines different from that in towns. An important factor is the richer environment and greater body of natural experience open to the country child, but until recently there have been no enterprising teachers in rural areas to base their teaching on these facts. Local surroundings should be the basis of country education, and the syllabus of work done could accordingly be flexible and free. Realizing that the country child must live on and by the land, we should arrange that his education should be based directly on the life of the countryside. For this purpose, adequate land around rural schools is essential in order to provide for school gardening, playing fields and a school estate. School gardening was at one time a device to occupy the spare time of older boys; but now, in progressive areas, it has come to be the nucleus of the teaching in woodwork, drawing, composition and arithmetic: it has also attracted the interest of parents. Village surveys are being increasingly organized and have educated children in the history, geography and biology of their district. In the hands of good teachers who keep abreast of modern knowledge, education for rural life could be fuller, freer and less materialistic than the education ordinarily given in towns.

Mr. Henry Morris, director of education for Cambridgeshire, said that education for rural life must be independent of the great towns, the culture of which is largely commercialized. The solution, however, can not be found in a single village; but in groups of villages forming a region centred around a large village or small country town. Modern transport makes this easily possible. Even so, reorganization far more extensive than a Hadow reorganization of schools is required. The school buildings ought to house a senior school in the daytime and a community centre in the evening. Such a solution is provided in the village college, which focuses the social, cultural and artistic activities of the countryside in one centre, architecturally appropriate, where adults and children are freely educated. A village college can thus cater for drama, dancing, horticulture, public health and recreation and those communal activities in song and ceremony that enrich the corporate life. The planning of this college on a generous scale, with ample land and attractive buildings, requires foresight and experience. It needs considerable expenditure; but such expenditure would be socially beneficial in the highest degree, and above all, it would help us to make the fullest use of the leisure that applied science is making possible.

Prof. N. M. Comber dealt with the contribution of universities to education for rural life, and deprecated the brevity and elementary nature of the courses they provide in agriculture. Moreover, such courses emphasize practical and utilitarian matters; they should be broadened to include some study of cultural, social and recreational life of the countryside. The nation at large should endeavour to understand the significance and importance of the countryside, and some appreciation of rural life should be inculcated in the training courses for teachers.

Mr. T. S. Dymond referred to the influences on rural education of raising the school-leaving age. While many country schools are doing good work under the Hadow scheme of reorganization, large numbers fail to educate suitably the senior children. More individual work should be expected of them, more craft work should be introduced, particularly a variety of crafts such as carpentry, metal work, simple mechanics, dairying, fruit-bottling. In short, the education must be largely vocational. For those who are leaving school, some form of part-time continued education would be of great value, even if it took the form of young farmers' groups or women's institutes. Vocational work is valuable by cultivating the ability to acquire knowledge through experience, and thus stimulating self-reliance, initiative and a desire to learn.

Mr. G. W. Pierce, speaking as a village headmaster, claimed that the village school as it exists to-day is doomed. The new rural school will serve a wide area and will hold 220–280 children, but it must be located right in the countryside—the more rural the better. 8–10 acres of land are necessary in order to allow for ample playing fields and gardens. He deprecated the tendency of local education authorities to convey country children to the nearest town to be educated with town children; it is far better for town children to receive a rural education than for rural children to receive an urban education. The quality of the teaching staff is all important: the teachers must be interested in rural life, for a rural bias is essential in all subjects of the curriculum, particularly in arithmetic, gardening, science, handwork, cooking and geography. Practical work is of the first importance and should occupy at least half of the school hours. Further, it is educationally admirable that boys and girls should become interested in plant life and bird life.

Sir Arnold Wilson claimed that education for rural life involves in practice education for husbandry in all its branches. This implies that the teaching staff must be convinced believers in rural life. Agriculture is more vital to the nation than is generally realized: statistics show that agriculture offers very varied occupations and unrivalled scope for individual talent. Moreover, it is a healthy way of living. The passive idea of education is false; enthusiasm for doing should be inculcated. Germany shows a different outlook upon husbandry in every walk of life: there agricultural workers are being suitably trained, and country life is held in honour; there is no rigid distinction between school years and working years, and diplomas are awarded after suitable practical experience combined with a variety of instruction. The future of Great Britain depends on rural life, for it is in the country-side that food is produced, fresh air is abundant and a variety of occupations and experience is present. He believes that great help would be given in the enjoyment of the privileges of country life if the best part of education were given after the age of sixteen years.

Land Transport

IN his presidential address on October 15 to the Institute of Fuel (see NATURE, October 31, p. 752), Sir Philip Dawson dealt with the subject of transport on land. The end of the nineteenth century may be called the electrical age, but so far as Great Britain is concerned, since electrical power is mainly produced by steam, its application to traction only means the consumption of fuel transferred from the rolling vehicle to the power-house producing electricity. In countries where electricity can be produced by water-power, this agency may largely affect the total consumption of solid and liquid fuel. Hence the French call water-power *la houille blanche* (white coal). We are faced to-day with the fact that, despite the high efficiency in producing light, heat and power now obtained in the combustion of coal, the output of coal in Great Britain has diminished from 287 million tons in 1913 to 223 million tons in 1935.

In 1921, there were 269,000 horse-drawn vehicles on the roads; in 1934 there were only 23,000. There are now nearly 2,500,000 vehicles on the road propelled by internal combustion engines. The use of internal combustion engines burning heavy oil has been slowed down by the tax of 8*d*. per gallon imposed on Diesel oil. In Germany the use of this kind of engine is advancing rapidly. The risk of fire and explosion of heavy oil is much smaller than with petrol, and this would be a great advantage in time of war. Transport by road both for passengers and goods is rapidly increasing. This is due mainly to the increased facilities which the road offers both to the passenger and the trader. There were no less than 435,000 goods vehicles employed on the road last year. There are nearly twice as many people employed directly and indirectly in road transport as in railway transport. The motor-spirit and fuel-oil consumed last year exceeded two million tons, and increased by their taxation the revenue of the Government by forty million pounds. It is estimated that Germany will consume more than two million tons of light synthetic oil this year, more than half of which will be home-produced.

Much could be done in Great Britain to encourage the domestic supplies of petrol by the increased production of benzol by the gas and coke industries. Diesel-electric trains are coming into favour both in Germany and the United States. The great disadvantage of the steam locomotive as compared with Diesel and electric traction is that it consumes fuel when not actually performing useful work.

The electrification of railways, main line as well as suburban, is constantly increasing throughout the world. In Great Britain, the Southern Railway has made the greatest progress in this direction. All the electricity it uses for traction is supplied by the Grid from steam-operated power plants. Sir Philip quoted with approval the Weir report, which stated that electrification places in the hands of the traffic manager a new system which enables him to offer a more attractive transport proposition to the public and the characteristics of which are capable of extensive development. The adoption of electric haulage for metropolitan and suburban lines nearly always produces increased traffic. The additional cost of the increased train mileage has been much less than the increase in the revenue resulting therefrom. Even in countries where electricity is generated by steam, its largely increased use in industry and for haulage must bring about a decrease in the use of coal in consequence of the greater efficiency realized.

In conclusion, Sir Philip said that every effort must be made in Great Britain to utilize the thermal energy contained in coal for the production of all forms of power, so as no longer to have to rely on fuel imported from overseas, as we have to-day, for operating services which are vital to our national existence and commercial prosperity.

Maya Culture in the Highlands of Guatemala

THE Carnegie Institution of Washington, which under its Section of American Aboriginal History is conducting a comprehensive investigation of the anthropology of Central America, covering the archæology, history under Colonial administration, and physical characters and constitution, linguistics, and social conditions of the modern inhabitants, has undertaken a further investigation in the highland zone of Guatemala. Here a year of mound excavation has already made a substantial advance towards a settled chronological sequence in culture, which is one of the principal aims in present-day archæological research in Central America.

A mound in the neighbourhood of Guatemala city, to be known in future as "Haminaljuya", the "Hills of the Dead", is now being excavated by Dr. A. V. Kidder on behalf of the Institution and at the invitation of the distinguished archæologist, Dr. Antonio Villacorta, Minister of Public Education, and his son, Sr. Carlos Villacorta, director of the National Museum of Guatemala. This mound is one of a hundred situated within a restricted area of half a mile by one and a half miles. The area, as part of the highland region, is already characteristically known to archæologists as a source of material of the 'archaic' period, for which evidence is also forthcoming from other sites, such as the Valley of Mexico, and from the lowest levels of Uaxactun in the Province of Peten. Certain indications, however, had led Dr. S. K. Lothrop some years ago to infer that remains of a later period might occur in the area, perhaps even so late as the Maya Old Empire; and only last year Dr. Kidder himself, while pointing out that the highland region had served more as a highway for trade and migration than the lowland jungle country, suggested that its sites might be expected to provide extremely valuable information as to the chronological interrelation of the various ancient cultures, particularly as it was probable that stratified remains would be discovered.

These prognostications, it is stated in a preliminary report on the first season's excavation of the mound issued by the Carnegie Institution (*Bull.*, 4, 6), have been strikingly verified. Even so far as operations have proceeded up to the present, it is evident that occupation of the mound was far more prolonged than had been thought probable. The mound presents resemblances to the third of the four sequent stages in the tentative classification of the culture of the lowland city of Uaxactun, the oldest site yet excavated in the Maya area. This would bring Kaminaljuya at least down to the Old Empire; but finds from the site also present resemblances to those from Teotihuacan, the Toltec city in the Valley of Mexico.

Not only, then, does the evidence of the finds from Kaminaljuya reduce Dr. Lothrop's inference to proved fact, but it also has provided the stratified remains which Dr. Kidder desired. Quite apart, however, from their importance as evidence for cultural sequence, the finds are of an exceptional intrinsic interest. Not the least surprising result of the investigation was that after two pyramids superimposed upon a third had been revealed, still another was found beneath the third. Each of the outer three showed certain differences. The two outer pyramids, for example, rose to a surmounting platform by terraces, the third (reckoning here, as elsewhere, from the interior outward) showing three levels, whereas the second rises steeply in a single slope, and still carries a balustrade of twelve steep steps, while this feature in the third pyramid had been torn away when it was dismantled for the building of the fourth.

In examining the place of the stairway in the third pyramid, three tombs were brought to light; and a fourth, still unexamined, was found under the staircase of the second pyramid. The burials in the three tombs, which have been opened, have produced a wealth of objects, personal ornaments in jade, crystal and other material, pottery, including some remarkable painted ware, obsidian spear-heads, and other funerary offerings, which when more carefully examined at leisure will certainly throw much new light on Maya art, burial customs and culture generally.

The tombs were great square pits, vertically sided, dug in the volcanic deposit, and measuring twelve feet square and twelve feet deep. Originally they were roofed with logs, which, when found, had rotted away and let down stones and earth on the contents. An interesting feature of these tombs is the arrangement of the body, which, with attendant circumstances, suggests the interment of a high priest or ruling chief. In the first tomb the personage interred had been placed in a sitting position in the centre of the floor. On three sides of the skeleton lay single human skulls and on the fourth the skull of a jaguar. In the second (Tomb III) the principal skeleton was that of a middle-aged male. The body had again been placed in the middle of the tomb in a sitting posture with the legs crossed. It had been loaded with ornaments, and at the side was a heap of pottery, in which were two human effigies in clay. At the feet of the skeleton lay the bones of a young woman and vessels for serving food, a milling stone for grinding corn, and other utensils. In a corner were the bones of a small dog. With the principal personage of the third tomb (Tomb II) were two others, possibly slaves. All were in the sitting position, facing south. This was in some ways the richest tomb of all and contained many unique pieces of pottery.

Dr. Kidder suggests in connexion with the burials, basing his opinion upon the evident character of the interment, that the custom of building pyramids superimposed one upon another may have been due to the custom of demolishing the pyramid, of which the deceased had charge at the time of his death, and preparatory to building another for his successor.

Developments in British Telegraph Services

IN a paper read to the Institution of Electrical Engineers on November 19 by L. H. Harris, E. H. Jolley and F. D. Morrell, details are given of many of the engineering developments which have taken place in the inland telegraph service of the British Isles during the last few years.

It is now clear to engineers that the use of underground cables solely for direct current telegraphy is wasteful and that modern developments in amplifiers and filters enable a direct current cable to carry many more circuits. In 1929, the international council (C.C.I.T.) standardized the speed of the teleprinter, and two years later the spacing of the carrier frequencies to be used for voice-frequency telegraph working was also standardized. In 1931 the Post Office installed and operated a London–Dundee 12-channel system, developed and manufactured in Great Britain, which met completely the requirements laid down by the C.C.I.T. A year later the London–Glasgow–Belfast 18-channel system was installed. The introduction of demand telephone trunk working created a shortage of trunk telephone circuits and it was decided to convert practically the whole of the inter-urban telegraph network to voice-frequency working. The telegraph cables thus thrown idle were used for telephone purposes. The number of voice-frequency telegraph channels has doubled during the last three years. The revolution in the methods used in telegraphy has been very thorough. By 1934 scarcely an item of traditional telegraph plant remained in the inland service.

Cable companies, news agencies and newspapers make considerable use of these circuits for speeds up to 100 words per minute. Voice-frequency channels are nearly always used, and even such important circuits as direct extensions of Atlantic cables are employed in this way. An increasing number of newspaper companies now rents telephone circuits on which they provide or rent equipment for alternative speech or pictures and multi-channel voice-frequency telegraphy.

The telex service, which gives the alternative of teleprinter working to speech over the telephone network, as distinct from a separate teleprinter exchange system, has also progressed. One of the latest developments of the private teleprinter services has been the introduction of broadcast systems. In these, facilities are provided and maintained, up to the limit of the number of machines at the central office, by which the renter can transmit simultaneously to any reasonable number of outstations. News agencies and police services are finding these methods very useful.

The 18 frequencies used by the carrier currents in the voice-frequency channels are the odd multiples of 60 cycles from 420 to 2,460. The currents are generated by a multi-frequency machine, driven by a motor fitted with a centrifugal governor which regulates the field current and controls the speed to within ± 0·25 per cent. Great progress has been made in standardizing 80 volts for all telegraphic purposes, and in eliminating the 24, 40 and 120 volts employed for local and main-line batteries when direct current was used. The maintenance of the voice-frequency network is carried out by the ordinary repeater-station staff, who rapidly have become familiar with the new methods. The average duration of interruptions of commercial circuits due to causes which can be attributed to the voice-frequency method do not exceed five minutes per week. In the case of private wire renters, they report faults directly by telephone using the voice-frequency terminal.

It has not been found necessary to make use of sub-audio (infra-acoustic) circuits in the British Isles, except for a few cases in which submarine cables are involved. The London–Jersey duplex teleprinter circuit is one of these cases. It is in series (composited) with the Channel Islands telephone circuit consisting of a single core unloaded submarine cable. Two duplex teleprinter circuits have been installed in the continuously loaded submarine telephone cable between Blackpool and Port Erin (Isle of Man). These circuits are noteworthy as they use only seven volts for transmission so as to avoid the risk of affecting the loading material used in the cable. Neglect of this gives rise to 'cross-talk' due to minute changes in the inductance.

The difficulties experienced at first in maintaining teleprinter speeds constant have been overcome. The difference in the speeds now seldom exceeds one per cent. The speed is checked by means of stroboscopes and synchroscopes. The latter instruments have been found to be much the more accurate. In the case of telephony, voice-frequency signalling methods and improvements in transmission technique have led to development in the direction of extending the automatic system to include the trunk circuits. This avoids the delays and costs of intermediate operating. Similarly in telegraphy, the elimination of probably 50 per cent of the operating transactions and delays would be possible by means of through automatic switching from the sending to the receiving office. The present voice-frequency network makes a framework for such a scheme which would have been quite impracticable under the old physical line conditions.

Telegraphy is now in a position to share in the rapid advances recently made in the telephone field. The teleprinter with its typewriter keyboard, the elimination of the distance factor by voice-frequency methods and the cheaper private wire telegraphic rentals should prove a boon to the commercial world.

Humboldt's Plan in 1836 for a World Magnetic Survey

EARLY in 1836 Alexander von Humboldt sent a letter to the Duke of Sussex, as president of the Royal Society, inviting the co-operation of the Society in the organization of a world magnetic survey. The letter was referred to Christie and Airy, whose report was read to the Royal Society on November 24, 1836. As von Humboldt's suggestions had a great influence on the steps afterwards taken, a few extracts from the report are given here:

"In this letter," said Christie and Airy, "M. de Humboldt developes a plan for the observation of the Phenomena of Terrestrial Magnetism worthy of the great and philosophic mind whence it has emanated and one from which may be anticipated the establishment of the theory of these phenomena. . . . The Baron de Humboldt and MM. Arago and H. Kupffer having, by the co-operation of many zealous observers, succeeded in establishing permanent magnetic stations extending from Paris to China, M. de Humboldt solicits, through His Royal Highness the President, the powerful influence of the Royal Society in extending the plan by the establishment of new stations. The plan which he proposes . . . is that magnetical observations, whether of the direction of the horizontal and inclined needles, or for the determination of the variations of the magnetic force, should be made simultaneously at all stations, at short intervals of time, for a certain number of hours and at fixed periods of the year precisely similar to the plan which has been recommended and adopted by Sir John Herschel with reference to observations of the barometer and thermometer." He also "considers that it deeply interests the advancement of mathematical and physical sciences that, under the auspices of His Royal Highness the President, the Royal Society should exert its influence in extending the line of simultaneous observations, and in establishing permanent magnetic stations in the tropical regions on both sides of the equator, in high southern latitudes and in Canada. . . . Should the proposition meet with their concurrence he begs that the Royal Society will enter into direct communication with the Royal Society of Gottingen, the Royal Institute of France and the Imperial Academy of Russia, to adopt the most proper measures to combine what is proposed to be established with what already exists".

After a full review of the subject, Christie and Airy went on to say, "By referring to M. de Humboldt's letter, it will be seen that the plan of observation so comprehensively conceived by him, has been most powerfully and liberally patronized by the Governments of France, of Prussia, of Hanover, of Denmark and of Russia; indeed it is quite manifest that a plan so extensive in its nature must be far beyond the means of individuals, and even of scientific societies, unaided by the governments under which they flourish. . . . To suppose . . . that the Government of this, the first maritime and commercial nation of the globe, should hesitate to patronize such an undertaking . . . would imply that our Government is not alive either to the interests or to the scientific character of the country, and would show that we had little attended to the history, even in our own time, of scientific research, which has been so liberally promoted by the Government. . . . We therefore feel assured that, when it shall have been represented to the Government that the plan of observation advocated by the Baron de Humboldt is eminently calculated to advance our knowledge of the laws which govern some of the most interesting phenomena in physical science . . . that the patronage to the undertaking which is so essential to its prosecution will be most readily accorded. . . ."

Educational Topics and Events

CAMBRIDGE.—M. Krook, research student of Gonville and Caius College, has been elected to an Isaac Newton studentship, and E. N. Rowland, of Gonville and Caius College, to an additional Isaac Newton studentship.

Prof. W. V. D. Hodge, Lowndean professor of astronomy and geometry, has been elected into a non-stipendiary fellowship at Pembroke College.

GLASGOW.—Dr. William Marshall Smart, chief assistant in the Observatory and lecturer in mathematics in the University of Cambridge, has been appointed regius professor of astronomy, in succession to Prof. Ludwig Becker, who has resigned.

Mr. Oliver Shewell Franks, fellow and prælector in philosophy of Queen's College, Oxford, has been elected to the chair of moral philosophy rendered vacant by the death of Prof. A. A. Bowman.

Dr. John Dougall has been appointed Gibson lecturer in the history of mathematics.

Sir Frederick Crombie Gardiner has given £10,000, and the trustees of his brother, the late Mr. William G. Gardiner, of Moraig, Stirling, have also allocated £10,000 to the University, towards the provision of a new Medical Institute to be erected in connexion with the Western Infirmary. This is to be known as the "Gardiner Medical Institute" and will be at the disposal of the regius professor of medicine for the purpose of teaching and research.

In a recent address to the General Council of the University, the new Principal, Sir Hector Hetherington, mentioned that during the last six years, whereas £130,000 has been received for scholarships, only £47,000 has been received for general expenditure on lands, buildings, equipment, etc. He pointed out that, at present, aid to the University is more important and beneficial than the provision of additional scholarships.

LONDON.—The following degrees have been conferred: D.Sc. in chemistry on E. E. Jelley, for published works on chemical microscopy and photographic chemistry; D.Sc. (engineering) on R. W. Bailey, for published works on creep and stress in metals, etc.

OXFORD.—Dr. Simon Flexner, director of the Rockefeller Institute for Medical Research, has been appointed George Eastman visiting professor for the academic year 1937–38.

Prof. R. V. Southwell has been elected a member of Hebdomadal Council.

Lord Nuffield has been elected an honorary fellow of Pembroke College.

Dr. F. Simon, of Balliol College, has been appointed University reader in thermodynamics for five years from October 1.

It is proposed to confer the honorary degree of D.Sc. early next year on Dr. J. D. Pollock, chairman of the Metal Industries Company and of the British Oxygen Company, and a Carnegie Trustee.

SHEFFIELD.—Prof. F. C. Lea, formerly professor of mechanical engineering, and Prof. J. Husband, formerly professor of civil engineering, have been given the title of emeritus professor.

The following appointments have recently been made: Dr. K. Mellanby, Sorby fellow, as honorary lecturer in zoology; Mrs. H. Mellanby, as honorary research assistant in the Department of Zoology; Mr. J. E. Stanworth and Mr. F. R. Harris, as research fellows in the Department of Glass Technology.

Dr. J. C. Paisley has resigned his post of junior assistant bacteriologist.

A NUMBER of Commonwealth Research Fellowships, tenable by British subjects at certain American universities, are offered for award in 1937 by the Commonwealth Fund of New York. Twenty-four Ordinary Fellowships are offered to candidates living in Great Britain or Northern Ireland who are graduates of a university therein. Two Dominion Fellowships are available to British candidates living in a British Dominion or Colony who are graduates of a Colonial university. There are also five Service Fellowships tenable by British candidates holding appointments overseas under the British Government or a British Colonial Government, and three Home Civil Service Fellowships tenable by candidates holding appointments in the Home Civil Service. The Fellowships are tenable for two years, and are not open to women. Further information can be obtained from the Secretary, Commonwealth Fund Fellowships, 35 Portman Square, London, W.1.

"AN Educational Platform for 1936", formulated at Stanford University, California, last July by the Dean of the School of Education as a result of a conference held there on "Curriculum and Guidance", has been published in *School and Society* (Sept. 5). It is a fairly comprehensive reasoned statement of principles, aims and aspirations, and is valuable as an indication of some trends of thought in academic circles in the western States of America. The impact of the recent rapid advances in technological science on a society unprepared to readjust its institutions, which are consequently "jarred to their very foundations", calls for a concentration of effort on the part of educators to fit the younger generation and, so far as possible, the community at large, to take part in the social advances indispensable for the preservation of a democratic State. Hence the educational programme must stress the study of present conditions and the potentialities of the future, the study of the past being ancillary thereto, and the teacher's position shifting from that of merely transmitting information about things which have been done to one of dynamic influence in social evolution. Associated with this is the development of what is referred to as "the guidance service" to aid the student in defining his goals — vocational, social-civic, recreational and health. But guidance should imply more than mere counsel. The 'platform' envisages school education as an *apprenticeship* for worthy adult life, including the actual doing under supervision of things which constitute desirable living. This implies provision for participation in many varied activities outside courses of formal study. The last item in the proposals calls for a thorough-going broadening and raising of the standards of teacher-training institutions.

Societies and Academies

Edinburgh

Royal Society, November 2

E. B. Bailey and W. J. McCallien: Perthshire tectonics; Schiehallion to Glen Lyon. E. M. Anderson's stratigraphy has been confirmed, with minor additions. The Dalradian boundary has been shown to be a slide affected by considerable overfolding. This overfolding has brought into one and the same district Dalradian with and without a Blair Atholl component. Other slides include the Schiehallion slide, as spectacular as any thrust in the North-West Highlands. Large-scale inversion is a commonplace in the district. Often the older Blair Atholl Series is found downfolded into the younger Perthshire Quartzite Series. The Loch Tay inversion extends fifteen miles across the strike. All the big recumbent folding and refolding is towards the south-east.

Ralph Dennell: Feeding mechanism of *Apseudes talpa* and the evolution of the peracaridan feeding mechanisms. The almost hemispherical maxillipedal epipodite of *Apseudes talpa* closely enwraps the base of the second thoracic limb. A valvular flap, on its anterior border, lying outside a typical Malacostracan filter exit, enables the epipodite to draw a filter current from the filter chamber. The maxilla bears minute, but typical, filter setæ; but the maxillipedal brushing setæ are largely prevented from scraping them by a lower row of maxillary setæ. Fine food particles are retained mainly by the brushing setæ, and not by the filter setæ. The probable evolution of the feeding mechanisms of the Peracarida is described.

Mabel S. Fraser: The vascular supply to the follicle-bearing Ranunculaceæ. The main point emerging from this detailed study is the variation in the vascular supply to the carpellary whorl—a variation which is particularly marked in the acyclic group. In a single gynæcium there may be variation in the origin of the carpellary bundles and also in the number of traces entering each carpel. Thus no basic formula could be established for any one species. No evidence was found in support of the theory of carpel polymorphism as applied to this group. The tendency towards a basic five-trace supply to the carpel is noted, and the author is inclined to support the view expressed by Eames, that the primitive carpel was probably a palmate sporophyll, with a basic five-trace supply.

W. J. van Stockum: The gravitational field of a distribution of particles rotating about an axis of symmetry. The gravitational equations are considered in the interior of a rotating axially symmetric distribution of particles which are describing their paths without mutual interaction. The general solution of the equations is shown to depend upon an arbitrary solution of the equation

$$\frac{\delta^2 V}{\delta r^2} + \frac{\delta^2 V}{\delta z^2} - \frac{1}{r}\frac{\delta V}{\delta r} = 0.$$

As an example, the gravitational field of an infinite rotating cylinder is considered in detail.

T. M. MacRobert: Some formulæ for the associated Legendre functions of the second kind, with corresponding formulæ for the Bessel functions. The generalized Bessel's integral is employed to evaluate a number of integrals and series involving Bessel functions regarded as functions of their orders. Corresponding results are also obtained for the Legendre functions of the second kind.

Paris

Academy of Sciences, October 26 (*C.R.*, 203, 753–832).

Robert Esnault-Pelterie: The extension of the principle of the limit law in dimensional analysis.

Nikola Obrechkoff: A theorem of Laguerre.

Ottokar Borůvka: Singular matrices. Admitting priority of Ed. Weyr.

Serge Bucheguennce: The surfaces of Bianchi.

Werner Fenchel: Generalization of a theorem of Brunn and Minkowski concerning convex bodies.

Jean Dieudonné: The zeros of derivatives of rational fractions.

Pierre Boos: The properties of symmetry of the integral curves of differential systems of the second order.

Robert d'Adhémar: The moment of initial impulse and the inclination of the rifling grooves. The periods of virtual instability of projectiles.

René Lucas: The specific heats of liquids and gases. By taking into account the existence of transversal waves, hitherto neglected, it is possible to develop a quantic theory of the specific heat of liquids analogous with that of solids.

James Basset and Maurice Dodé: The solubility of nitrogen in water at ultra-pressures up to 4,500 kgm./cm.^{2}. Starting with a certain pressure, about 300 kgm./cm.^{2}, the solubility of nitrogen in water diminishes as the pressure is increased. The possible effects of traces of oil derived from the compressor is discussed, and it is proposed to repeat the experiments with an apparatus excluding this possible source of error.

Félix Cernuschi: The conservation of energy and Shankland's experiment. An argument that the results of Shankland, assumed to be exact, do not necessarily imply the abandonment of the law of conservation of energy.

Pierre Jacquinot and Gaston Dupouy: New measurements of the variation of the deviations with the field in the Zeeman effect with mercury.

Léon Bloch, Eugène Bloch and Pierre Herreng: The absorption spectra of sulphur dioxide and of hydrogen sulphide in the Schumann region.

Georges Bruhat and Pierre Guénard: Study of the circular dichroism of solutions of camphor in organic solvents. The solvents used were carbon tetrachloride, hexane, cyclohexane and benzene. The only effect of the change of solvent, in the absorption region, is a displacement as a whole, without appreciable modification, of the curves of dichroism and rotatory dispersion.

Joseph Hrdlička, Miloslav A. Valouch and Ladislav Zachoval: Contribution to the study of the Debye-Sears effect.

Maurice Curie and Pierre Preiswerk: The activation of thulium by slow neutrons.

Joseph Wiemann: The Raman effect and organic chemistry: the structure of the 'oses' and the Raman effect. Solutions of xylose, glucose, sorbose, arabinose, galactose, lævulose, rhamnose, and mannose were examined, and none of these gave a line corresponding with the C : O linkage, from which it would appear that none of these, in solution, has either an aldehydic or ketonic structure.

Emile Carrière and Raymond Lautié: The formation of the molybdenum oxides Mo_3O_8 and Mo_2O_5.

Martin Battegay and Gerard Mangeney: The aldehydes of 1.nitro 2.methylanthraquinone.

J. A. Gautier: A new series of *N*.hydroxyalkoxyl-α-pyridones.

Marc Tiffeneau and Mlle. J. Gutman: Molecular transformation in the cyclanic series. Isomerization of the epoxides derived from 1.benzyl 4.methyl 1.cyclohexene and 1.benzylidene 4.methyl cyclohexane.

Joseph Hoch: The action of organo-magnesium compounds on the ketoximes.

Henri Moureu and Maurice Dodé: Remarks concerning the mechanism of the formation of the monochlorhydrins of glycols. Studies on the kinetics of the reaction between water, chlorine and ethylene with formation of ethylene chlorhydrin. The results do not support the hypothesis that ethylene oxide is an intermediate product.

Alfred Maillard: The proportion of deuterium in the light hydrocarbons from petrols of various sources of origin. The petrols have been burnt in an internal combustion motor and the water condensed from the escaping gases. The heavy hydrogen from natural hydrocarbons varies with the origin, and is about double that found in ordinary water.

Jacques Fromaget: The syntectonic origin of the conglomerates and limestone breccias of the north-west of Tonkin.

M. and Mme. Fernand Moreau: The antagonism of some cations in cultures of *Saprolegnia*.

Mlle. Marie Thérèse Gertrude: The elaboration of carbon material by plants in aquatic media.

Jean Cheymol: Results on the structure of verbenaloside. It is a lactone, and salts of the corresponding acid have been prepared. It is also a ketone and contains a methoxy group.

Robert Weill: The cnidome of the cladonemides *Eleutheria dichotoma* and *Cladonema radiatum*; its cycle and interpretation.

Jean Brouardel: Nuclear phenomena of conjugation in *Trichodina patellæ*.

Pierre Drach: Allometric growth and sexual dimorphism in the Brachyura.

Roger Husson: The fauna of artificial subterranean cavities.

Albert Vandel: The mode of distribution of the sexes in *Trichoniscus* (*Spiloniscus*) *provisorius* (2). Deuterogene females and monogene females.

Constantin Levaditi, Mlle. Rachel Schoen and Louis Reinié: The experimental reproduction of lymphogranulomatous conjunctivitis (disease of Nicolas and Favre) in the chimpanzee.

Paul Durand, Paul Giroud, Edouard Larrivé and André Mestrallet: The experimental transmission to man of "maladie des porchers".

Cracow

Polish Academy of Science and Letters, October 5.

W. Sierpinski: A theorem on definite functions in any infinite ensembles.

Mlle. H. Plamitzer: Contribution to the method called *regula falsi*.

S. K. Zaremba: Contribution to the discrimination of the singular points of ordinary differential equations.

K. Guminski: The luminescence of barrier anodes of aluminium. Study of the influence of the concentration of the electrolyte on the intensity of the luminescence of the anode, the distribution of the intensity in the spectrum of this emission in the case of an anode of pure aluminium, and the effect on this distribution of the addition of other metals to the aluminium.

K. Dziewonski, L. Sternbach and A. Strauchen: The reactions of β-naphthylamine with thiourea.

J. Szaflarski: The thermal conditions of the *Zmarzle Stawy* in the High Tatra.

W. Friedberg: *Terebralia bidentata* = *Cerithium lignitarum* in the Miocene of Poland. Specimens of *C. lignitarum* collected near Zalesce (Volhynie), except that they are slightly smaller, correspond with *T. bidentata*.

J. Zacwilichowski: A new method of obtaining aberrant forms of Lepidoptera under the influence of chemical reagents. Changes of colour can be produced by injecting the chrysalids with suitable chemical reagents. The results may serve in the analysis of the genesis and causes of aberrations in the Lepidoptera.

J. Gallera: A case of embryonic triplogenesis.

St. Zarnecki: The migrations of young sea trout from Dunajec to the sea.

Sydney

Royal Society of New South Wales, September 2.

C. A. Sussmilch: Evidence of a change of sea-level at Botany Bay. A borehole, drilled near Spring Street, Botany, some few years ago, passed through six successive beds of peat, five of which are below sea-level, the depth of the lowest being 87 ft. below sea-level. Afterwards a well was sunk to a depth of fifty feet, and at the bottom of this, which is 24 ft. below sea-level, a number of well-preserved tree stumps were found *in situ*. The peat beds have resulted from the accumulation of layers of terrestrial vegetation above sea-level, and their occurrence now below sea-level indicates a change of sea-level of a minimum amount of 87 ft. The presence of the tree stumps *in situ* supports this. The occurrence of six different beds of peat, separated from one another by beds of sand, suggests that the movement was an intermittent one, each bed of peat representing a pause in the movement. It is considered that the movement was a rising of sea-level, rather than a subsidence of the land.

W. M. Holman: A study of phosphate solubility in certain New South Wales soils. Recently, Gaarder has used the solubility of the soil P_2O_5 at different *p*H values as a means of determining the nature of the combinations of P_2O_5 in the soil. The phosphate status of certain N.S.W. soils was examined by determining the solubility at different *p*H values within the *p*H range 1·5–8·5 of both native and added P_2O_5. In a black soil from Edgeroi, P_2O_5 is combined largely as basic calcium phosphate. Typical red soils from the western wheat districts are poor in respect to soluble P_2O_5, but have little capacity to remove P_2O_5 from solution. In certain red clay soils from Lismore, no P_2O_5 is soluble under the experimental conditions within the *p*H range 3–8. A large excess of sesquioxide colloids, chiefly hydrated Fe_2O_3, is responsible. When silicic acid colloid is added to these soils, the sesquioxides are deactivated and P_2O_5 is liberated.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, November 23

Royal Geographical Society, at 5.30.—Geographical film on "The Mount Everest Expedition of 1936", by members of the Expedition.

Tuesday, November 24

Royal Society of Arts, at 4.30.—H. E. Laffer: "The Empire Wine Industry".

British School of Archæology in Jerusalem, at 5.0—(in the Rooms of the Society of Antiquaries, Burlington House, W.1).—An open public meeting.

The Right Hon. W. Ormsby-Gore, M.P.: Address.

P. L. O. Guy: Description of the proposed archæological survey of Palestine.

Chadwick Public Lecture, at 5.15—(in the Great Hall. British Medical Association, Tavistock Square, W.C.1), —Sir Francis Fremantle: "The Doctor's Mandate in Parliament".*

Wednesday, November 25

Bedford College for Women, at 5.15.—Prof. John Jewkes: "Social Policy and the Depressed Areas".*

Royal Society of Arts, at 8.—Lady Hart Dyke: "The Lullingstone Silk Farm".

Friday, November 27

Royal Institution, at 9.—Prof. Edward Mellanby, F.R.S.: "Recent Advances in the Treatment of Disease".

Saturday, November 28

Newnham College, Cambridge, at 5.—Lord Rutherford, F.R.S.: "Modern Alchemy" (Henry Sidgwick Memorial Lecture).

The Service of Unified Knowledge

JUST a century ago the library of that mighty book hunter, Richard Heber, came under the auctioneer's hammer, and two hundred and two working days were consumed in dispersing a hundred and twenty thousand volumes—a noble collection which yet did not represent more than a fragment of that portion of the world's thought heretofore collected between the covers of printed books.

What a change has come over the scene in the century that has passed! The staid astronomy over which Airy presided has expanded into a world picture wherein countless universes stream through space, and temperatures are reckoned in millions of degrees. The physical sciences are altered out of all recognition; their content has increased in an incredible ratio and, concurrently with an unprecedented increase in the technique of accurate measurement, has developed a doctrine of uncertainty which prescribes a limit to the accuracy of our knowledge. Theories of evolution have appeared on the scene, crossed the stage, and disappeared—possibly to reappear in modified form. Social systems, apparently stable, are in a state of flux; the father of sixty years since could train his son to a trade or profession with the reasonable expectation that the society in which he lived and moved would remain indefinitely stable; the father of to-day sees no such prospect. Youth is healthily critical of the fundamentals of our social system, and discourses copiously—sometimes perhaps a little superficially—concerning dialectical materialism and the Hegelian theory. And, if 'Whitaker' be a trustworthy guide—the year 1934 saw 15,436 new volumes thrown into this weltering confusion of assertion, argument and denunciation, in Great Britain alone.

What can be done about it? If there is one thing more certain than another, it is that some appreciation of the magnitude and mode of action of these forces of disintegration, of these rapidly changing aspects of political, moral and religious thought, of the social repercussions of the advances of scientific knowledge, must be the possession, not merely of an oligarchical or aristocratic governing class, but also of every man who by his vote or otherwise may influence the policy and outlook of the community of which he forms a unit.

Government to-day is much more of an art than a science, and grave questions of national policy are settled as the result of waves of mass-emotion—emotion which may or may not have its origin in a wise, altruistic and rational attitude to the problems of life. It will always be so—great movements of humanity will ever be determined by the forces directed by the emotions and passions of mankind; and it is the business of all who can help, to do so by assisting each one of us to form, so far as his limitations of capacity and opportunity will permit, that background of ordered knowledge which so much enlarges his outlook and thereby his ability to think clearly and wisely, and to direct his emotions to a worthy end. Moreover, the need presses; in more than one community where shallow draughts of psychology and philosophy have intoxicated the brain, we see a growing habit of depreciation of the actions of the intellect and of undue exaltation of emotional and intuitive processes.

We can at least provide the means towards supplying this need—we can, granted goodwill and energy, put at the disposal of every man, learned and unlearned, ordered statements of present-day knowledge in all branches of life and learning that the mind of man has traversed, and concerning which he has recorded his thoughts, his difficulties and conclusions in the pages of a book. Such a statement is an encyclopædia.

The notion of an encyclopædia is old enough, as old as the appreciation of the organic unity of knowledge—of the fact that the totality of knowledge is something more than the sum of its parts. The name is no older than 1541, the date of publication of Ringelberg's "Cyclopædia" at Basel; the notion is possibly as old as Aristotle, whose mind was essentially encyclopædic—as Pliny's was not. But the great incentive to encyclopædia-building came from the labours of Francis Bacon, whose attempt at a systematic classification of knowledge fired the imagination of Diderot and inspired the labours of D'Alembert.

Our countryman, Ephraim Chambers, had the root of the matter in him when he remarked that, in his view of an encyclopædia, one should "consider the several matters not only in themselves, but relatively, or as they respect each other; both to treat them as many wholes, and as so many parts of some greater whole". A truly admirable ideal; whether the "Cyclopædia or Universal Dictionary of the Arts and Sciences" (two volumes, folio; London, 1727) fulfilled these generous aspirations is another matter.

It cannot be too strongly emphasized that a true encyclopædia is something more than a bare summary of the knowledge of its day. Its articles may or may not be dashed off hastily—in the age of intellectual ferment that produced the great French Encyclopædia, articles were written at a white heat of enthusiasm, and it was just *because* that enthusiasm was linked with the forces of reason and of knowledge the French Encyclopædia became such a mighty weapon for the cause of progress. For that very reason it rallied, in the words of one of its great historians, "all that was then best in France round the standard of light and social hope".

So, too, the age that saw the passing of the Reform Bill saw the birth of a desire for the spread of positive knowledge that resulted in the publication of those remarkable volumes (twenty-seven of them, and two or three appendix-volumes) known as the "Penny Cyclopædia". He who has these volumes on his shelves will more willingly part with more pretentious cyclopædias. The wealth of articles contributed by Augustus de Morgan will never lose their value; and the whole encyclopædia is a noteworthy record of the aspirations and limitations of a phase in our history marked by a special enthusiasm for "the particular go" of material things.

It was also, we note in parentheses, the England of the Oxford Movement. But it was also the England of the Society for the Diffusion of Useful Knowledge—a Society the activities of which produced an inimitable passage in "Crotchet Castle"—and the "Penny Cyclopædia" faithfully reflects that aspect of its age. Calculus and chronology are there in full measure; the artistic and mystical side of life find but scanty record.

What type of encyclopædia will most fittingly serve the needs of our own age? Mr. Wells's vision sees a World Encyclopædia where all that is best of everything that need be said is gathered together in one great series of volumes—the best thoughts of the best writers—"selections, extracts, quotations, very carefully assembled with the approval of outstanding authorities in each subject, carefully collated and edited and critically presented".

It may well be so; this represents a high, though not an unattainable ideal. But though the difficulties are great and will have to be considered, we need not assume that the gain in authority of a collection and collation as nearly perfect as this imperfect world of ours will permit, will involve a loss of unity if control is entrusted to a band of learned workers informed with an enthusiasm for their task, and having a clear perception of the social needs of their age. It is, however, vitally necessary to realize such difficulties before embarking on the task of preparing an encyclopædia the influence of which may be so far-reaching.

Yet a further possibility should be considered. *Entia non multiplicanda sunt praeter necessitatem*, a dictum which is specially true of encyclopædias. But, broadly speaking, there is room and need for three types: the encyclopædia wherein the articles are written in terms of specialized knowledge; the more popular encyclopædia written with an eye to the needs of the layman; and a really critical bibliography of existing knowledge which shall discriminate between the needs of the specialist and those of the layman.

Such a critical bibliography—an almost indispensable preliminary to the greater task—would place at man's disposal a weapon of immense social value.

Topics of the Age for Everyman

The Columbia Encyclopedia
Compiled and edited at Columbia University. Clarke F. Ansley, Editor in Chief Pp. v+1949. (London, Bombay and Sydney: George G. Harrap and Co., Ltd., 1936.) 63s. net.

THIS massive volume, twelve inches by nine inches in its superficial dimensions, nine and a half pounds in weight and containing, within the compass of its nineteen hundred and fifty pages, not less than four and a half million words, represents a heroic attempt on the part of editor and publisher to give to Everyman such information on the topics of the age as Everyman is likely to seek—and, moreover, to give him pointers which shall tell him where further detailed and authoritative information may be found.

This is a principal function of a modern *compact* encyclopædia. Tendencious disquisitions are not wanted here; detail should be cut down to the minimum; fine writing is anathema—"no flowers by request," said Leslie Stephen to contributors to the "Dictionary of National Biography"; the information conveyed should be both judicious and judicial; and the pointers should direct the way to the latest and fullest sources of information. Though, it must be confessed, the pointers are occasionally missing where they might well have been supplied, these necessary qualities are well shown in the "Columbia Encyclopedia", and the crucial questions now arise: What is the *content* of the volume? Over what regions of thought and of fact does it range?

These questions can be answered only by a process of sampling, and sampling processes are peculiarly liable to error. Everyman interested in theology may seek aid in the matter of the distinction between homoousian and homoiousian, or the thinkings and doings of sublapsarians, supralapsarians and semi-Pelagians, while remaining completely indifferent to the discovery of the neutron or the meaning of the Œdipus-complex; and contrariwise. (May it be said at once, and in parenthesis, that Œdipus, his complex and the neutron receive due notice, and that the Pelagian heresies and the views of the semi-Pelagians are handled in clear and scholarly fashion, but that the only entry made under the term 'supra' deals with the supra-renal gland—a pleasant, and not inapposite illustration of the trend of modern thought as interpreted in this encyclopædia.)

Still, if Everyman has a fairly inquisitive and ranging disposition the sampling process may not be devoid of significance. So far as the process has gone, it indicates, as was to be expected, that the outlook of the work is American. This is not an adverse criticism; it is a mere statement of fact, and does not imply that English interests do not receive adequate treatment. On the gazetteer side, for example, we find small American townships entered with a degree of particularity which it would be quite impossible to observe universally. But the English entries are adequate, and thoroughly up to date, as may be tested by reference to very recently formed boroughs.

The historical and political articles are remarkable for their clarity and for the completeness with which they supply essential and no more than essential information. In the articles which deal with theological topics, the omission of one or two subjects of special English interest is noteworthy. The accounts of the various Christian churches are admirably executed, the tenets of quite obscure sects being duly and briefly elucidated; but while Bishop (pop. 1159) and Bishopville (pop. 2249) are entered and described, the English Church dignitary is passed unmentioned, and he who would seek to know something of the duties of an archdeacon must remain content to think of him as one who exercises archidiaconal functions.

The scientific articles are definitely qualitative in character, in the sense that they abjure any attempt at symbolic exposition. Thus there is no entry to be found under the headings 'Differential Calculus' or 'Integral Calculus' and, under the general heading 'Calculus' a short entry of some two hundred words disposes of the whole matter. Similarly, the terms 'exponent' and 'logarithm' are simply and briefly explained, but there is no entry of the corresponding series, and these articles, again, contain no references to texts in which further information may be found. One or two references to mathematical literature are entered *s.v.* 'Mathematics'. Indeed, it is not only mathematical symbolism that is abjured, for the compilers are at pains to avoid any specialized jargon. Thus, to take a simple random example, 'Wallflower' is defined as an "ornamental perennial shrub of the mustard family" and the salient facts are given concerning its origin and cultivation, further descriptive notes on the family being found under the heading "mustard".

Although finer details are occasionally missing, the physical, chemical and astronomical articles are, in general, admirable examples of lucid compression. The articles under the headings 'variables', 'nebulæ', 'planetesimal hypothesis', 'hydrogen', 'X-rays' and 'photometry' may be cited as typical. A few of the more modern terms have been overlooked or treated very briefly in comparison with the space allotted to classical work. The policy of qualitative, or rather, of non-symbolic exposition—for there is no lack of numerical detail, where numbers are necessary—is one that has obviously been pursued of set purpose. It has everything to commend it, and the editor is to be congratulated on breaking away from the older tradition of exposition. He who can understand a symbolic expression of the binomial theorem or of a matrix is not likely to seek further information in a popular encyclopædia ; and, in the great majority of such cases, he knows where to seek his information, and is scarcely likely to need those pointers which are so useful to the reader interested in historical or literary matters.

What of the articles which are concerned with matters literary ? The lives and work of the great ones of the earth are expounded well and clearly, and most of the lesser lights find adequate mention, though Alfred Austin achieves a five-line immortality, whereas his fellow-laureate Pye ("Better to err with Pope, than shine with Pye") is left to languish in an unnamed obscurity.

It is when one comes to those very minor stars concerning whose merits and interest opinions may differ so widely that lacunæ begin to manifest themselves. Is Everyman entitled, as of right, to know something of the life of that odd figure, John Buncle, and of his equally odd creator, Thomas Amory ? Or of the author of "Valentine Vox, Ventriloquist", and his illustrator, Onwhyn ? The English reader may seek, but he will not find. On the other hand, the American, Gilbert Imlay, whose main interest to English readers lies in his relations with Mary Wollstonecraft, receives a notice of some twenty lines, and this may be taken as a fair example of the American leanings of an encyclopædia, which after all is called the "Columbia Encyclopedia".

Again, the claims of taste may be heard in the matter of the inclusion or omission of certain topics. The personal side of crime and criminology does not bulk largely in the pages of the encyclopædia, and Everyman interested in these matters may look up the story of Prof. Webster (one of our few academic murderers) only to be fobbed off with the life-history of the blameless and dull Noah Webster of dictionary fame. And why should the poisoner Thomas Griffiths Wainewright ('Janus Weathercock' and friend of Charles Lamb) be chosen, and Henry Wainwright, of the Whitechapel Road, left ? These be snobbish distinctions.

Seriously, this must not be interpreted as adverse criticism. From every point of view, the work is crammed with matter of very deep interest to the English reader. In the end, the test of such a volume, the compilers of which must necessarily pick and choose, decide to insert this and omit that, is : How often does it let one down ? The result of a fairly severe test shows that the occasions are relatively small.

Editor and publishers are to be congratulated on the completion of an arduous undertaking which fully deserves the success that doubtless awaits it.

A. F.

International Co-operation in Astronomy

Transactions of the International Astronomical Union
Vol. 5 : Fifth General Assembly held at Paris, July 10 to July 17, 1935. Edited by F. J. M. Stratton. Pp. viii+429. (Cambridge : At the University Press, 1936.) 15*s*. net.

IT is difficult to speak without admiration of this volume and of the indefatigable editorship of Prof. F. J. M. Stratton, formerly secretary of the Union, to whose almost unaided efforts we owe it. Following a brief report and financial statement from the Executive Committee, there appear the reports of the presidents of the thirty-one Commissions which form the Union. These deal with topics so diverse as notations, meridian astronomy, chromospheric phenomena, wave-lengths, nebulæ, radial velocities and stellar statistics. Amongst so much that is good, each reader, depending upon his ignorance or his knowledge, will select some reports as outstanding ; for his part, the reviewer would choose Fowler on wave-lengths and Jackson on meridian astronomy.

The remaining two fifths of the volume is concerned with accounts of the meeting of the Union as a whole, and of the meetings of the separate Commissions. While some of the Commissions, notably those on Ephemerides, Minor Planets, Wave-Lengths and Nebulæ appear to have taken advantage of the meeting in Paris to hold useful discussions, others appear to have indulged in little more than formal business.

It is in this respect that the present Astronomical Union differs so markedly from its predecessor, the International Union for Co-operation in Solar Research. In that body, if one may safely infer something of its proceedings from the published *Transactions*, informal discussion at the meetings took precedence over previously prepared formal reports, and even after an interval of twenty years, one can still recover something of the stimulation to research which those meetings must have provoked. Unquestionably there were giants in those days, and it would be difficult to imagine meetings attended by Schwarzschild, Schuster, Rydberg and Kayser which were not exciting. It is not to this, however, that the difference between the two Unions is to be ascribed; indeed, a meeting which has its Eddington, its Russell, its Shapley and its Milne can scarcely be said to be lacking in colour. Rather it would appear that, while by its own statutes the present Union puts first the facilitation of "the relations between astronomers of different countries where international co-operation is necessary or useful", the International Solar Union, in the words of its founder, put research first. Speaking at Mt. Wilson in 1910, Hale said:

> "It seems to me obvious that the most important work of the Union has been, and must continue to be, the stimulating of research. That is, it seems to me to be more important for us to come together, and talk together, than to carry on formal co-operative investigations. That has been our idea, I think, from the very beginning, and I believe that the Solar Union has accomplished it by stimulating research."

International co-operation is good, but individual research is better, and in the opinion of the reviewer the International Astronomical Union can only hope to reach the standard set by its predecessor when discussions on research problems take precedence over co-operative schemes and formal business.

H. H. P.

Mr. Fisher's History of Europe

A History of Europe
By the Rt. Hon. H A. L. Fisher. Complete edition in one volume. Pp. xv +1301. (London: Edward Arnold and Co., 1936.) 10*s*. 6*d*. net.

THE recent issue in one cheap volume of Mr. Fisher's already popular work is an event of considerable educational importance. There can be no doubt of the great vogue of this attractive reprint. It will become the most widely read book of general history for this generation of Englishmen, as Gibbon was for our forefathers of a century and a half ago, and there is a touch of Gibbon—a Liberal Gibbon—in its learning, spirit and style. It deserves, therefore, careful scrutiny and judgment, as much for its own great merits as for the sake of those whom it will influence. Moreover, the chief side on which it is open to criticism is that which comes most naturally within the scope of this journal To that alone we must confine our attention here.

Mr. Fisher's book does not purport to be merely a political history of Europe, and it contains many suggestive passages—notably those on Dante and Luther—dealing with other aspects of the life of Europe beside statecraft. On the aspect of intellectual life which specially interests us here, handsome homage is accorded in the introductory chapter. The passage deserves quotation

> "It is, moreover, to Europe-man that the world owes the incomparable gifts of modern science. To the conquest of nature through knowledge the contributions made by Asiatics have been negligible [this, of course, is far too sweeping] and by Africans (Egyptians excluded) non-existent. The printing press and the telescope, etc., etc., together with all the leading discoveries in physiology . . . are the result of researches carried out by white men of European stock. It is hardly excessive to say that the material fabric of modern civilized life is the result of the intellectual daring and tenacity of the European people."

This is a magnificent exordium, and later on at the beginning of the second volume, there is an excellent chapter on the various aspects of the Renaissance with due reference to Copernicus and Vesalius, and again, in the third volume a few pages on Darwin and Spencer. But sound in tone as these passages are, they form but a small digression in the 1,300 packed and brilliant pages which narrate the characters and actions of the heroic Vikings, the founders of dynasties and the leading statesmen and warriors who make up the traditional historical pageant of Europe. It has never been better mustered and presented in English than in these pages; but is it the most important part of the truth? One asks the question, not with any wish to disparage the value of the actual matter of which Mr. Fisher treats, or with the absurd idea that a historical work should be an encyclopædia and mention everything, but quite seriously and with a sincere desire to have his considered judgment, if he would give it. Two contrasted cases, nearly contemporary, will make the point clear. L. Cornelius Sulla, "an aristocrat of fine culture and licentious manners", whose calculated butcheries came to nothing, receives three pages. Archimedes, one of the greatest and most constructive minds who ever lived, is not mentioned at all. Nor indeed are most of the men of similar type throughout the story.

Our object here, however, is not to set up a series of such unprofitable, almost inconceivable, comparisons. There is a much more substantial question involved to which Mr. Fisher himself alludes in his preface. He there says, with modest pathos, that he is not one of those "wiser and more learned" than himself who can discern in history "a plot or rhythm", and that for him there is "only one emergency following another, and that the ground gained by one generation may be lost by the next". Surely it is just here that the growth of organized knowledge comes in to supplement, correct and give a background to the political story with its inevitable breaks and contretemps. For knowledge grows and works, no doubt with temporary lapses, but never with any permanent loss of what has been secured. Nor is organized knowledge a separate thing which can be left alone by the political historian to be treated by others. It enters intimately, continuously and with increasing dominance into the ordering of the life of the people, which we all agree is the main subject of history.

One consideration alone is sufficient to prove this in relation to the subject of Mr. Fisher's book. At the best period of the Roman Empire in Europe there was, it has been estimated, a population of some 70 million persons in the area, largely enslaved. There are now more than 400 millions, leading on the whole a peaceful and industrious life and all free—at least from legal slavery. It is the greatest and the most beneficent revolution which the world has seen and must be regarded as the goal of any history of Europe. Many causes have led the way. Better political organization is no doubt a large factor, and moral advance assisted by the Christian church and doctrine. But some of us hold that the organized knowledge of Nature, applied to industry, should have a leading place among the causes, and we look anxiously in any account offered to us for some recognition and analysis of this factor. It is not only essential to the understanding of the past, but it also gives to those disturbed by present events (among whom Mr. Fisher includes himself) a better standing towards the future. Here is the plot and the rhythm, and it is sadly to seek in this otherwise magnificent achievement. F. S. MARVIN.

Anthropology as it is

The Economics of Primitive Peoples
By Dr. Stephan Viljoen. Pp. 282. (London: P. S. King and Son, Ltd., 1936.) 12*s*. 6*d*. net.

WHEN first we set eyes on Negroes or Chinamen, their faces seem all alike. So do the minds of all non-Europeans. To the anthropologist, all men outside the trousered world are of one mental hue, called primitive. Since they are all one kind, what is true of one tribe can unhesitatingly be applied to all the rest from the North Cape to Cape Horn. If one is crassly conservative, all are (p. 30); if marriage is an extremely loose bond, say in Tahiti, it must be so in the Solomons; a place has been found where a woman's ambition is satisfied with presenting a son to her husband, so this is characteristic of all 'primitive' women.

Those who have had first-hand experience will demur at such generalizations and challenge the statements that lack of food leads to war (p. 75), that the arts and crafts are held in contempt by the men (p. 84), that primitives like to carry their most precious possessions on their person (p. 233). He is sure to know at least one tribe that does not conform, and perhaps a great number. But it would not be fair to hold the author responsible for the initial fallacy and its inevitable consequences. He has not undertaken to speak from experience, but only to mirror faithfully the views generally accepted, or at least discussed, in anthropological departments, not on economics alone, but also on a large number of subjects slenderly connected, such as couvade, human sacrifice, birth rites, metal working, etc. This is a work that is needed, especially by students.

For this task, the author is well fitted. Free from sectarian prejudice, or even from very decided opinions of his own, he can be content to record impartially the views of the recognized authorities. Sensible when critical, widely tolerant and eclectic, he has selected his materials well, put them together lucidly, and produced a very readable manual of anthropology as it is in 1936.

A. M. HOCART.

Schlacke und Vitamine:

die Schlackenkost als Behandlungsweg bei Krankheitszuständen. Von Prof. Dr. Hugo Salomon. Pp. vii+263. (Leipzig und Wien: Franz Deuticke, 1936.) 12 gold marks.

THAT anyone should be able to write some 250 pages on vitamins and roughage, in relation to the treatment of disease, is in itself surprising. When, however, we consider the author's name along with the facts that his book is published in Leipzig and Vienna and that he describes himself as of Buenos Ayres, we turn with some curiosity to see what it is all about, noting in passing that the dedication (to the author's wife) appears on a page headed by a text from Houston Stewart Chamberlain.

After all, there turns out to be nothing very exciting or subversive in the book. The author is an enthusiast for diets with a high roughage content, which also frequently means a high content of water-soluble vitamins and possibly of carotene. He seems to advocate wholemeal bread ("Schrotbrot", "Grahambrot") as an essential dietary constituent in the treatment of conditions as pathologically diverse as catarrhal icterus, hypertension, eczema, tuberculosis, diabetes (*sic*) and migraine.

Actually vitamins come in for very little mention at all; it is almost as if they had just been put into the title "to make it harder". The author's belief would seem, therefore, to be that if you take care of the roughage, the vitamins will take care of themselves. We know of little evidence for this faith, if fat-soluble vitamins are included in the creed.

This book may be of some assistance to those who have to ring changes on laxative diets with the view of achieving palatability and variety. As a contribution to nutritional or biochemical science it does not, however, seem likely to make an epoch, but its extreme colon-consciousness may give it an interest for psychologists.

A. L. B.

Jabo Proverbs from Liberia:

Maxims in the Life of a Native Tribe. By George Herzog, with the assistance of Charles G. Blooah. (Published for the International Institute of African Languages and Cultures.) Pp. xiv+272. (London: Oxford University Press, 1936.) 10*s*. 6*d*. net.

PROVERBS are mere pin-points of a mass of communal wisdom and experience. A collection of proverbs is therefore meaningless unless to each saying there is added an account of the traditions and situations that give rise to it.

However well this may be done—and our authors have done it well and thoroughly—it is beginning at the wrong end. God and eternity, for example, do not appear as concepts that permeate life and inspire many things of which proverbs are the least; they are introduced merely as footnotes to pithy sayings. Those sayings are recorded with a phonetic minuteness which is entirely laudable, but the subject of titles is scattered in allusions that are sufficient only to convince us that they play an important part in Liberian society (pp. 28, 31, 196, etc.). On the other hand, many topics often go to one proverb. Thus, No. 192 is a multiple peg for the care of teeth, matrimonial troubles, sacrifices, etc.

The reader feels as would a student of zoology who, instead of being given the whole animal to dissect, is faced with 416 carefully arranged heaps of miscellaneous tissues, which, if it were possible to piece them together, would represent only a small part of the whole.

The greater the care lavished on the preparation, the more one regrets that the labour should have been invested at so small a yield. The authors are thorough, painstaking, accurate, minute; in fact, they have the virtues one expects in research, except a sense of purpose.

The Rational Quartic Curve in Space of Three and Four Dimensions:

being an Introduction to Rational Curves. By H. G. Telling. (Cambridge Tracts in Mathematics and Mathematical Physics, No. 34.) Pp. viii+78. (Cambridge: At the University Press, 1936.) 5*s*. net.

IN this tract Miss Telling has presented in compact form a great deal of information, gathered from various sources, which is not available as a whole elsewhere. The tract is divided into two chapters and a short appendix. The first chapter deals with the four-dimensional curve and its projective generation, invariants and the symbolical notation for them, fundamental polarity, trisecant planes, chords, quadratic involutions, director lines and planes, g-lines and the manifold G, the chordal J, the quartic surface K and its nodes, Segre cubic primals, and linear complexes containing the curve, or apolar to it. In the second chapter we descend to three-dimensional space, and consider quartic curves of the first and second kind, principal, quadratic, and cubic involutions; flexes, trisecants and Hessian points, the surfaces of Steiner and Veronese, and several special kinds of quartic curves. The appendix consists of a note on involutions on the four-dimensional quartic.

The style of the tract is clear and readable. The text is confined to the main line of argument without minor details, and the smaller points are summarized in the form of examples for solution by the reader.

H. T. H. P.

Mesure des températures

Par Prof. G. Ribaud. (Collection Armand Colin: Section de physique, No. 190.) Pp. 224. (Paris: Armand Colin, 1936.) 10.50 francs.

THIS handy volume on the measurement of temperature maintains the high standard we have been led to expect in the Collection Armand Colin. Prof. Ribaud has had wide experience of the subject both in Strasbourg and in Paris, and his larger volume "Traité de Pyrométrie Optique" is an authoritative account of one single branch. The amount of information contained in this smaller book is remarkable, and the presentation is admirable. The international temperature scale is adopted as standard, and the various methods of measuring high temperatures receive special attention. At the moderate price charged, the volume ought to be in the possession of all concerned in this important practical problem.

The McCoy Society's Expedition to Lady Julia Percy Island

By Prof. Frederic Wood Jones, F.R.S.

THE complete ecological survey of Lady Julia Percy Island was the first enterprise undertaken (in January 1936) by the McCoy Society for Field Investigation and Research. The McCoy Society was founded and organized by students of the University of Melbourne during 1935; and Lady Julia Percy Island lies off the coast of western Victoria (38° 24′ S., 142° E.). The island is separated from the mainland by a channel some five miles wide, and with as much as twenty fathoms of water intervening between it and the coast of Victoria to the west of Port Fairy (Fig. 1). The island is uninhabited, though various unsuccessful enterprises have at one time or another attempted to exploit it for grazing, for pig raising, or as a source of guano. It is more than 100 feet high, sheer on all sides, save for a precarious landing to the north, and is flat and exposed to all winds on its elevated plateau.

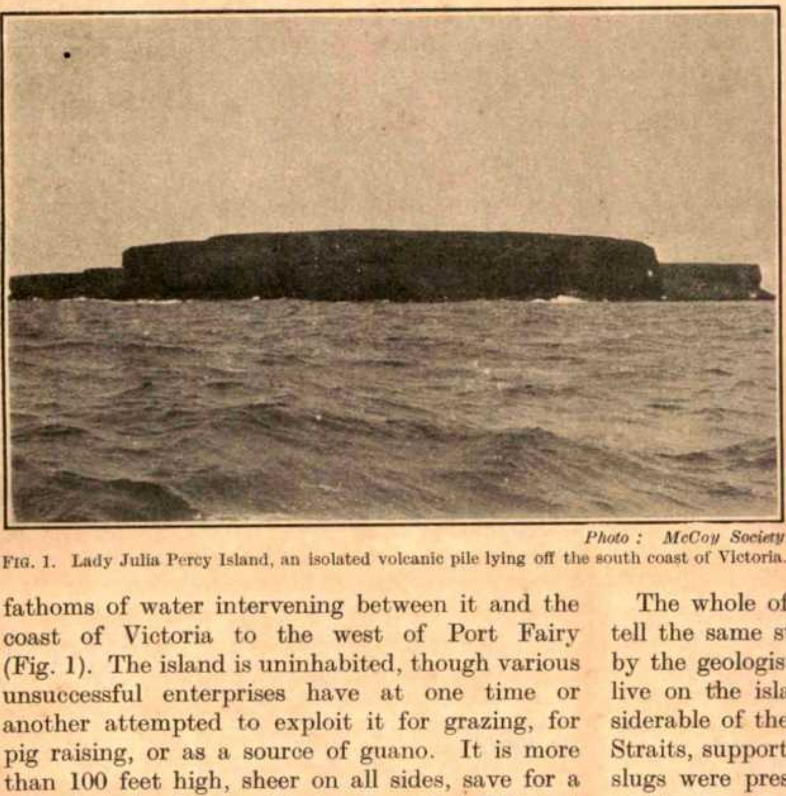

Photo: McCoy Society.

FIG. 1. Lady Julia Percy Island, an isolated volcanic pile lying off the south coast of Victoria.

The island plateau is a mile and a quarter long and three quarters of a mile wide. It was completely surveyed and mapped by the members of the expedition, and floral and faunal areas were precisely determined. A century ago it was covered with a dense, almost impenetrable, growth of the mixed bushy scrub that characterizes certain parts of the coast of the adjacent mainland. Some sixty years ago this dense scrub was still standing over the major portion of the island; but to-day the whole of the plateau is devoid of any growth more majestic than bracken fern and thistles. The whole plateau is, at present, a wind-swept area, clothed only by vegetation knee-high at the best, and at the worst, by loose volcanic soil or bare rock. This denudation of forest cover is due to human interference, for pigs were at one time turned down on the island, rabbits were liberated and are still living in their thousands, and sealers, fishermen and guano workers have cut down and burned the stunted and wind-blown trees that formerly covered the island.

Barren, inhospitable and forbidding though the island now appears, it proved to be a place of the most absorbing interest. The Bass Straits, St. Vincent's and Spencer's Gulfs, and the Great Australian Bight—the whole of the southern shores of Victoria and South Australia are dotted with islands, and I have visited more than thirty of them. But Lady Julia Percy Island, off Port Fairy, in Victoria, is different from all these. It is a pure volcanic island uprisen in the sea, and it has never formed a part of the continental mass of Australia, as have all the other offshore islands.

The whole of the flora and fauna of the island tell the same story as that which was unravelled by the geologists of the party. No land molluscs live on the island, though even the most inconsiderable of the islands of the Bight, and of Bass Straits, support a flourishing land-shell fauna. No slugs were present, and no amphibia. The only earthworm was not an Australian species, but was one introduced from Europe—an eloquent testimony to the reality of human interference in the dispersal of animal forms. There were no snakes, and the only reptile was a lizard which has an aptitude for being dispersed on every tiny fragment of land that lies off the Australian coast. No mammals live on the island plateau save the swarm of introduced rabbits, and the history of their advent is well attested. The only other mammals are the sea lions that resort to the island to breed, to raise their pups, to play, squabble and indulge in aquatic sports, and generally to have a wonderful time of fooling about that renders them the most engaging of animals for the casual observer—and the most lovable to the real student of Nature. It is a noteworthy fact that the sea lion of Lady Julia Percy Island differs profoundly, both in behaviour and in anatomical characters, from the species that inhabits the islands of the Great Australian Bight. This sea lion is a resident and local species, just as is the sea lion of the islands to the west, and it is much to be desired that local and uninformed legislation will never be directed towards the slaughter of these animals, the distribution of which is so restricted and the economy of which is, at present, so little understood.

The birds inhabiting the island are of two kinds, the land birds resident and breeding in the island, and the truly marine species that breed upon the plateau or among the rock boulders. In addition to these breeding species there are the visitors, both land and marine.

The resident and breeding species of land birds are of no especial interest. Native swallows, pipits, chats and red-capped dottrel breed in their accustomed sites upon the island, but only the pipits and the chats are numerous. The fine native swamp harrier is the dominant bird, and it breeds among the bracken ferns upon the open island plateau. On our arrival, these birds were so tame that it was possible to pick up the fully fledged young birds from their nests among the bracken; but, although they were not molested, they very soon learned all the wariness of their kind. They are the most conspicuous birds of the island and, at almost any time of the day, half a dozen or so could be seen floating above the plateau on the watch for young rabbits, penguins and mutton birds. Even the kestrels and the peregrines, which had apparently nested on the rock ledges of the cliffs, took a very minor part in policing the plateau. Introduced starlings and sparrows have reached the island, but they are inconspicuous and timid, and, for the most part, have their home in the volcanic cliffs and find their food upon the seal beaches.

Of the true sea birds, the Bass Straits mutton birds or short-tailed (or slender-billed) shearwaters (*Puffinus tenuirostris*) breed in large numbers in burrows tunnelled into the soft volcanic earth of the island plateau. The whale bird, ice bird or prion (*Prion turtur*) visits the island to lay its egg in the cavities beneath the vast basaltic boulders that strew the shore line, and the talus slopes of those parts of the island where the cliffs do not rise sheer from the water's edge. The shearwater and probably the prion are seasonal breeding visitors, but almost certainly the little diving petrel (*Pelecanoides urinatrix*) is a resident bird, breeding on the island and returning to it at dusk all the year round. The diving petrel is one of the most attractive of sea birds, a sturdy, manly, independent little fellow, with the most beautiful turquoise blue legs and feet and shining black and white plumage. He comes to the island only when the evening dusk has settled down, and as he comes he makes a little noise like a new-born puppy seeking its mother. From beneath some great boulder there comes the same little sound in answer, and soon, after flitting around like a bat in the dusk, he creeps into some chink, and a duet of little puppy-like love notes comes forth.

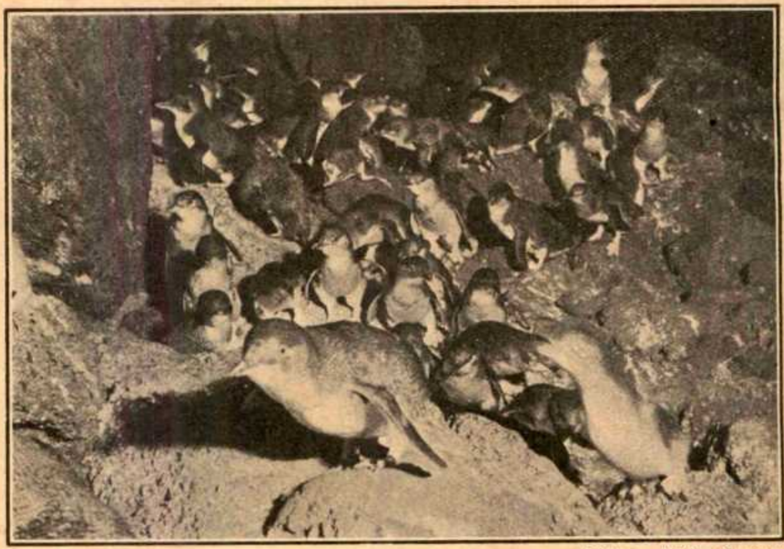

Photo: McCoy Society.

FIG. 2. The evening arrival of the penguins. The start of the long climb from the sea to the top of the island, taken by flashlight.

The prion is a ghost. A fluttering thing of pale grey-blue and white, a delicate wraith of a bird that comes moth-like into the beam of an electric torch and falls confused among the boulders—as it does at every lighthouse on the islands around the coasts of Victoria and Tasmania.

The Bass Straits shearwaters are birds of mystery. Anyone who has watched their evening arrival at a breeding island, seen their wheeling, watched them, as myriads of boomerangs, hurtling in the air, and followed their flutterings as they quarter the ground seeking their breeding burrows, has witnessed one of the most remarkable perfections of avian flight.

Then everywhere on the island are the penguins (*Eudyptula minor*). These little blue and white birds are among the most engaging of all the penguins, despite the fact that all their island activities are nocturnal. In solemn thousands they come ashore from the surf, and always at the same place, and in a sudden rush, every evening.

Every evening the whole company marches and hops up the same well-marked pathway to the island plateau and, at the plateau, disperses along numerous tracks to the breeding burrows. Every step of the way, every jump, every turn, is performed by every individual in the whole great army in exactly the same manner, and with the utmost solemnity. Every bird that, after the whole long journey, arrives at its home, finds two fluffy chicks awaiting it at the mouth of the burrow and regarding it with solemn expectancy. The little blue penguin is attractive beyond all birds in its serious and ordered ways of life, and in its queer sturdy independence that is combined with a most remarkable communal spirit. It is a strange thing that all these birds coming to the island at nightfall should forgather in the surf until their numbers are complete, and then, making a concerted rush through the breakers to the landing rock, start their long climb together (Fig. 2). For this coming and going is their time of peril, and a visit to any island upon which penguins breed tells its own tale. Penguin carcases, killed by harriers, peregrines and seals, strew the pathway from the surf to the breeding places; and around the rock holes or the burrows in which they breed are downy chicks ripped open by hawks or gulls. On Lady Julia Percy Island they did not have to run the gauntlet of gulls, for, strangely enough, these birds were not present on the island; but despite this, their mortality was very high.

During the hours of daylight, the island was a comparatively quiet place. Always there were the farmyard noises of the sea lions, for every sound, from the bleating of the lamb to the snarling of dogs and the lowing of oxen, came perpetually from the seal beaches. But when dusk came on there were added the indescribable groaning, mewing and caterwauling tumult from the mutton birds; the noise, rising from human snoring almost to donkey braying, of the penguins, and the newborn puppy sounds from the diving petrels and the prions. But despite all this, and the scarcity of fresh water, the members of the McCoy Society spent six happy weeks camped upon this volcanic island. They examined and collected everything, from soil bacteria to sea lions, and endeavoured to link the whole together in one complete ecological survey.

Terminology in Physics

By Prof. C. G. Darwin, F.R.S.

THERE has for some time existed an international committee, the 'S.U.N.', charged with the duty among other subjects of standardizing the nomenclature of physical quantities. So far as concerns such things as the names of units and their symbols it has proved effective. There has perhaps been a tendency for some of the members to point out that the majority were marching out of step; but in view of the very different approaches of different schools of thought, a certain latitude is perhaps permissible in the meaning and symbol of such a thing as *free energy*. This side of the question of nomenclature is adequately cared for, and is not the subject of the present article. Here it is proposed to consider certain obvious deficiencies and nonconformities in descriptive technical terms as they have arisen during the last decade or so in both English and American writings on atomic physics. It is not to be expected, perhaps not even to be desired, that any exact uniformity should be reached, but there are a number of cases where there is complete anarchy, and it is the aim of the present review to examine what principles should guide us in giving names to things, and possibly in a few examples to suggest appropriate solutions which may appeal to some of those who have not a conscientious preference for anarchy.

One of the greatest difficulties in the naming of physical ideas lies in the difficulty of translating a name out of one language into another. Consider, for example, the energy that remains in a body at the absolute zero of temperature. This idea was chiefly developed in German writings, and the quantity, following the polysynthetic spirit of the language, was called *Nullpunktsenergie*—name and definition in a single mouthful. Unfortunately, those who are charged with the literary side of education in England seem to hold that the best way to teach the writing of English is by drill in the very different rules of Latin grammar, and that nothing further is needed. The consequence of this curious opinion is that those, who will later have to invent new English terms, have been given no literary principles whatever to guide them in doing so, and therefore, since the idea was acquired in German, they can do no better than a literal translation, *zero-point-energy*, or even *zeropointenergy*. Now this is quite a different kind of name from any given when the original idea was invented by an English-speaking physicist; for example, if the α-particle had first been studied in Germany, we should, on this principle, be now calling its *range* its *reach-width*. Moreover, the translation of *Nullpunktsenergie* is a poor one, because we do not translate *Nullpunkt* as *zero-point*, but simply use the English term *zero*. It must rest with individuals to judge whether the expressions *zero-point energy*, *zero-point displacement* and so on (anyhow with only one hyphen) are so well established that their ugliness must be accepted, but it does seem a pity not to create an English technical term and speak of *residual energy*, etc., which could be done without ambiguity.

The expression *zero-point energy* is merely clumsy and ugly; but our next example is rank bad grammar. One of the great advantages of English is the latitude allowed in grammatical construction, but even this has its limits. Contrary to the rules of most European languages, it is admissible to use a noun as an adjective qualifying another noun, and this makes it unnecessary to coin many adjectival forms that would otherwise be needed, but it is not allowable to use a noun to qualify an adjective. One may not infrequently see in learned journals such a phrase as "This may be proved by *quantum theoretical* methods". What part of speech is *quantum* here? Some writers, perhaps conscious of offence, run the two words into one—a pure Germanism. Others hyphenate them, and if the expression must be used at all this is the least intolerable form. The proper English form would be *quantum theory methods*, though even that is very clumsy, and *quantum methods* is quite good enough. However, for such a fundamentally important idea there is need for a real adjective, if only to make the contrast with *classical*. Moreover, there is absolutely no need to have the word *theory* (or the word *mechanics*) in the name, and so the right procedure is to coin the adjective *quantal*. To justify its adequacy it is only necessary to notice the impossibility of finding anything that would be *quantally* right, but *quantum-mechanically* wrong.

The general difficulty about the translation of technical terms is that when an idea is first invented one is not sure if it will be worth translating at all, and later, when its utility is established, one is so accustomed to the awkward literal translation that one is like the cricketer who was asked the origin of the 'yorker' and replied, "I don't see what else you could call it". In the choice of a name for a new idea there are several alternative methods. First it is easy to overrate the danger of taking an ordinary word and giving it a technical meaning: witness such words as *force*, *strain*, *susceptibility*. In spite of the double meanings, these are good names, but not all such words have been so well chosen; the word must be recognizably a technical term, which means that there must be no likelihood of its ordinary use being needed in the same context as its technical use. The difficulty of this method of choosing a name is that the word will always have a whole set of mental associations different from the new intention, so that the inventor is conscious of objections against any choice; for this reason it is inadvisable to stretch the meaning of a common word very far.

Another method of nomenclature gives up the problem altogether by simply taking the name of the inventor. This is often a good method, but it must not be carried too far or the reader will have to construct a special dictionary in order to remember the meanings of the various names. Another confusion arises when two things, cognate but different, are named after the same author. For example, there are a *function* and *equations* and a *principle*, all named after *Hamilton*. The first two belong together and are habitually called after him, but the *Hamiltonian principle* is something rather different, and is better called, by a slight misdescription, the *principle of least action*. Another thing to avoid with this method is what appears to be a growing fashion, the stringing together of a sequence of the names of all those who have worked at a subject. There is a most useful process in quantum theory often called the *Wentzel-Kramers-Brillouin method*, and it is no disparagement of the brilliant work of these writers to say that this is a very inconvenient name. If no better technical name can be found, then physics should borrow a rule established in taxonomic biology and take the name of the author who had the strict priority of publication; in the present case it happens that it would be none of the three names above, for the method has been discovered no less than four times independently, and *Jeffreys* has the priority.

Another way of making a name is to construct it from parts out of the classical languages, and this method has the great advantage that the word, being a new one, is immediately recognized as being a technical term. A thing like *entropy* has to be given some sort of name, though the idea is really incapable of any short description, and we feel that this is a better kind of name than the artificial *gas*, even though Aristotle would have been equally unable to make anything of either. There are, however, many words which do aim at explaining themselves, so that the classical scholar, perhaps repressing a shudder at faults of synthesis, would have some idea what they meant, and the guiding principle for these ought to be that their composing parts should be fairly well-known words in the original language; for this reason, Latin is perhaps more suitable than Greek. Following this line, and without suggesting that established practice should be changed, it seems a pity that one must use the word *hœmatopoietic*, instead of *sanguinific*, always supposing that there are objections to the honest and simple *blood-making*.

Yet another method is to take a word straight out of some foreign language and use that. This is a method that needs much caution; for the borrowed word must be such as will fit into a spoken English sentence. Consider Gibbs's *ensemble*. It is a most embarrassing word to have to speak in a lecture, since all the letters have different values from those in the accompanying words. Even the skilled bilinguist has to 'change gear' in the middle of his sentence, and the less accomplished can scarcely fail to exhibit the deficiencies of his international culture. When such a word has been adopted, the proper course is boldly to give every letter its English value[*]. This word also exhibits the general difficulty of nomenclature. In French it does not really describe the idea at all well, since a *together* does not convey the idea of the simultaneous consideration of a set of quite separate motions of an assembly of atoms. Indeed, one would naïvely suppose that it meant the assembly itself, and such a word as *collection* seems to describe the idea better in English than does *ensemble* in French. As it turns out, the French word, used in English and anglicized, is best of all, but this may be partly because the inventor had the field entirely to himself for many years, so that his word has been accepted without having to prove its superiority over possible rivals. German words on the whole fit the English mouth better than French, but their uncongenial length gives them an alien character much more marked than that of an anglicized French word; we may accept *eigen*-functions, etc. (though the more usual prefix would have been *auto*-) but most others are unsuitable.

There is quite a different matter in which our present terminology is bad; unfortunately, sometimes in well-established practice. This is when two words which express opposite ideas sound nearly the same. To make a contrast between *intra-molecular* forces and *inter-molecular* forces confuses listener, reader, printer and sometimes even speaker as well. Here the right course is undoubtedly to make names which, even if less exactly suitable, sound quite different; the proper contrast to *intra* is *extra*. A worse example is *microscopic* and *macroscopic* when used in physics. To the inventor, this contrast may have had a pleasing epigrammatic flavour, but when the freshness has gone it becomes fantastic. We have two diametrically opposite ideas described by eleven letters with only one of them different, and they are such that the pronunciation of either in some of the English dialects would give the impression that the other was meant[*]. Both words are objectionable. *Microscopic* in this contrast habitually refers to things far too small to be seen in any microscope; it might just do in the popular sense of 'awfully small', but if a change is to be made we might as well get it right. *Macroscopic* is worse, because μάκρος is not one of the words otherwise used for derivatives, so that it will not convey its meaning to any but a scholar, and to be understood by others the word ought to have been *megascopic*. We want a word which the dictionary would describe as 'of, or pertaining to, bulk', and the best seems to be *molar*. It is true that this word has other meanings both in physical chemistry and in dentistry, but there is little danger of confusion. The contrasted word would be *atomic* (better than *molecular* because so much less like *molar*), since this describes the actual scale of magnitude which has hitherto been misdescribed as *microscopic*.

Finally we may refer to a less important matter, but one which makes an inconvenient gap in our language; this is the non-existence of an ordinal number corresponding to the cardinal number *zero*. In the literature one can find the expressions, "Bessel function of *zero* order", "*null* approximation", "*zeroth* law of thermodynamics", where in each case the next of the sequence would be called *first*, not *one* The word *zeroth* is a terrible hybrid, but the mere fact that it has been tried shows that the need of a distinction between ordinal and cardinal is really felt. On the whole, this seems to be a case for the technical use of an ordinary word, and the word *null* might be adopted. It may be objected that it does not quite mean what is wanted; of course, it has not meant it hitherto, for if it had the question would not arise, and this paragraph would not have been written. But it is a true adjectival form connected with the number *zero*, and so seems to fill the bill with less strain than any other word.

---

[*] In the same way *spin* has recently been adopted abroad, and it is to be hoped that it is called *shpin* in Germany, and nasalized in France.

[*] There is less danger in other languages when spoken, but a careless printer might give just as much trouble

There are no doubt other examples where improvements are needed, but the above are among the most glaring. The present article does not aim at inducing any exact conformity to its suggestions, but rather at directing attention to the real difficulty in the invention of suitable names for new things, and to the importance of doing it carefully. It may also be hoped that the actual suggestions may be of service, so that those future writers who have not yet firmly established their own usages may be induced to accept at least some of them.

Control of the Prickly-pear in Australia

THE control of the prickly-pears, *Opuntia inermis* and *O. stricta*, in Australia affords one of the most outstanding examples of the application of biological knowledge to economic purpose. It needs to be recollected that in 1925, about sixty million acres of grazing and farming land were known to be under infestation by prickly-pear in Queensland and New South Wales: the rate of spread of this scourge was stated to be reliably figured at almost one million acres a year. About fifty per cent of the infested territory was under dense prickly-pear, 3–5 ft. high, while the remaining area was affected by scattered infestations of varying intensity. To-day, the enormous rate of increase has been arrested, and less than ten per cent of the former great body of infestation survives: the whole of the primary pear in Queensland and much in New South Wales has broken down and collapsed. Approximately, twenty-five million acres of good land are now cleared and are being developed and brought under production.

The history of the campaign of control and eradication of prickly-pear has recently been briefly discussed by Mr. Allan P. Dodd, officer-in-charge of prickly-pear investigations, Brisbane. All interested in the subject should read his important paper in the September issue of the *Bulletin of Entomological Research* (27; 1936); a comprehensive history of the whole subject is promised in book form within two years time.

At the outset, the problem was how to eradicate a plant pest which had overrun, and rendered valueless, vast areas of territory. A pest, in fact, which could not be controlled by cultural, mechanical or chemical means, since the cost of widespread treatment by any of these methods rendered their application out of the question. The first steps towards applying biological methods of control were taken in 1912, and in 1920 the Commonwealth Prickly-pear Board came into being. This Board was charged with the study of prickly-pear in its natural home in America and the introduction, if possible, of insect or other enemies into Australia.

Since 1921, officers of the Board have visited most of the known prickly-pear regions of North and South America. Their investigations resulted in the discovery of about 145 species of insects which appear to be confined, in feeding habits, to prickly-pears and other Cactaceæ. Fungal and bacterial diseases also came in for investigation, but it was revealed that they did not afford much promise of direct utility, since many of these diseases were already established in Australia.

The Board's policy was based upon the conception that biological control offered best chance of success if a carefully selected group of species, working more or less in association, was established. A variety of promising species readily became adapted to Australian conditions and it was anticipated that their combined activities would, in course of time, result in gradual thinning out of the prickly-pear, in reduction of fruiting and consequently restriction of the spread of the pest.

It was quite unforeseen that the outstanding success evident to-day would have been effected by the agency of a single species of insect in the space of a few years. Nevertheless, this is what actually has happened, and the insect in question is the phycitid moth, *Cactoblastis cactorum* Berg. The fact is all the more remarkable for the reason that only 2,750 eggs (from the Argentine) of the insect were introduced into Australia, yet between 1926–30, about three thousand million eggs, laid by descendants of insects issuing from the original batch, have been distributed in the great prickly-pear areas. The eggs are laid by the moth in 'sticks', averaging seventy-five eggs in each: these 'sticks' are readily collected and artificially attached to the cladodes of the host plant. The resulting larvæ are gregarious, internal feeders which tunnel in companies through the tissues of the plant, thus also providing for the ingress of disease organisms. In this way the prickly-pear ultimately becomes so completely destroyed that it is reduced to a rotting mass of pulp. The various insects, established prior to the *Cactoblastis*, have either been largely suppressed or their activities nullified owing to competition with its larvæ. It is only locally, and in relation to a few species of *Opuntia* of lesser importance, that the *Cactoblastis* has proved more or less ineffective. Such problems, however, are being dealt with effectively through the operations of other phytophagous insects including cochineal (*Dactylopius*) and cerambycid beetles.

In any campaign involving the repression of pest plants through the medium of introduced species of insects, the potential danger that such insects, in a new environment, may transfer their activities to other host plants cannot be neglected. In the case of prickly-pear control, elaborate biological tests as to the host plant range and preferences of such insects have been a feature of inestimable value. Doubtful species have been excluded and none so far introduced has betrayed any tendency, other than of a sporadic nature, to resort to hosts outside the species of *Opuntia*.

We hope to refer to prickly-pear control again at a later date when the promised book, recounting full details, becomes available.

A. D. IMMS.

Obituary

Prof. T. M. Lowry, C.B.E., F.R.S.

THOMAS MARTIN LOWRY, who died at Cambridge on November 2, came of an old Cornish family which had been long connected with the Methodist Church; he was born at Low Moor, Bradford, Yorks, on October 26, 1874, the second son of the Rev. E. P. Lowry, senior Wesleyan chaplain and staff officer at Aldershot. He was educated at Kingswood School, Bath, and thence passed to the Central Technical College, South Kensington, in 1893, with a Clothworkers' scholarship, and was ultimately awarded the fellowship of the City and Guilds of London Institute. From 1896 until 1913 he was an assistant to Prof. H. E. Armstrong; in 1904–13, was lecturer in chemistry, Westminster Training College, and from 1913 until 1920 head of the chemical department in Guy's Hospital Medical School; in 1920 he was appointed to the newly created chair of physical chemistry in the University of Cambridge, a position which he held at his death. He married a daughter of the late Rev. C. Wood in 1904 and leaves two sons and a daughter.

During his long service with Prof. Armstrong, Lowry gained recognition for his delicate work in organic chemistry. The proficiency which he then acquired as a crystallographer expressed itself later in the aptitude which he displayed in applying exact physical methods of measurement to the solution of chemical problems; he developed a rare instinct for grasping the essentials of any subject which he attacked and for ensuring that the quantitative methods used were devoted to the measurement of something which was clearly defined. The vast mass of quantitative physical data collected by Lowry is thus not of merely ephemeral interest but will also provide useful working material for future generations of physical chemists.

During Lowry's first research work, he noted that the optical rotatory power of nitro-*d*-camphor solutions changes with lapse of time, and he early realized that this effect, which he termed mutarotation, arises from the tautomeric change of substances such as derivatives of camphor and of sugars. Mutarotation is dependent on the nature of the solvent, and the mutarotation of *d*-glucose can be arrested in such a hydroxylic solvent as cresol, or a basic one like pyridine, but proceeds almost too rapidly for measurement in a mixture of these solvents. Lowry thus showed that an amphoteric solvent is necessary as a catalyst for the mutarotation process, and built up his now well-known theory of prototropic change; it is largely on this work that the conception of dynamic isomerism advanced by van Laar became generally accepted.

Concurrently with his purely chemical work on mutarotation, Lowry studied the variation of rotatory power with wave-length, a subject which had been much neglected since the death of Biot in 1862. He demonstrated the validity of Drude's equation for simple substances and expanded the equation so that it covered the anomalous rotatory dispersion of *d*-tartaric acid and the tartrates; this formed the subject of the Bakerian Lecture before the Royal Society by Lowry and Austin in 1921. Lowry's later determinations of the rotatory power of quartz, made on a column nearly half a metre in length, both in the visible and ultra-violet, furnished data of the highest precision by which again the validity of the Drude equation was established. He turned next from the optical rotatory power of transparent media to that of absorbent media and studied the Cotton effect; here he was able to develop equations which adequately express the dispersion throughout the absorption band. Whilst Lowry's main work in this field bore on optical rotatory power, he also studied other optical phenomena, and during recent years had initiated a series of investigations concerned with the refractive dispersion of organic compounds.

During the Great War, Lowry devoted himself to problems connected with high explosives and acted as director of shell-filling from 1917 until 1919; he did valuable service on the Trench Warfare Committee and the Chemical Warfare Committee and was an associate member of the Ordnance Committee at the time of his death. His war services gained him the C.B.E. and the Order of St. Maurice and St. Lazarus. He took the D.Sc. (London) in 1899 and held the honorary degree of M.A. (Cambridge) and doctorates of science of Dublin and Brussels; he became a fellow of the Royal Society in 1914.

In addition to some hundreds of important papers published with numerous collaborators, Lowry wrote several useful books; the last of these, on "Optical Rotatory Power", was issued last year and will long remain a standard work on the subject. The immense amount of accurate experimental work which Lowry has left on record secures him a permanent place in the history of the science to which he was devoted. His old colleagues and students in the laboratory of physical chemistry which he built up at Cambridge will remember him as a staunch friend, an inspiring teacher and an indefatigable worker who has passed too soon from their ranks.

WM. J. POPE.

Prof. H. R. Briton-Jones

PROF. HARRY RICHARD BRITON-JONES whose untimely death occurred in Trinidad on November 3, following an operation for appendicitis, will be mourned by a wide circle of friends, scientific colleagues and past and present students of the Imperial College of Tropical Agriculture. He was born in 1893 and educated at Llandovery College, of which he was a scholar. He entered King's College, London, in 1912, proceeding to the Royal College of Science in 1913, where he took the associateship and, later, the diploma of the Imperial College. In 1915 he was commissioned in the R.G.A. and he gained the M.C. on active service, being eventually invalided from shell-shock, with the rank of captain. Attracted to the study of plant diseases, he re-entered the Royal College of Science to equip himself for phytopathological research; a short period was also spent at the Royal Botanic Gardens, Kew, in systematic study of the fungi parasitic on plants.

At the end of 1919, Briton-Jones was appointed mycologist in the Egyptian Department of Agriculture, but he left in 1923 to become mycologist at the Horticultural Research Station of the University of Bristol at Long Ashton. He was appointed professor of mycology and bacteriology at the Imperial College of Tropical Agriculture, Trinidad, in 1926 and dean of the College in the following year; he acted as principal on several occasions.

In Egypt, Briton-Jones devoted himself largely to the study of cotton and cereal diseases, publishing in 1925 the main results in a memoir entitled "Mycological Work in Egypt during the Period 1920–1922". At Long Ashton he was led to consider the influence of the nutrition and cultural management of the host plant on its susceptibility to parasitic disease, a subject which afterwards became increasingly predominant in his mind. While there, he published work on the cause of die-back of fruit trees, a problem not yet fully elucidated but in which the factors of nutritional and soil-moisture unbalance which he emphasized probably play a considerable part. On proceeding to Trinidad, he applied the same considerations to the diseases of permanent tropical crops, especially cacao and coco-nuts. His book on "The Diseases and Curing of Cacao" (Macmillan and Co., Ltd., London, 1934) was followed by a similar work on coco-nut diseases, but he did not live to see it published.

Briton-Jones's outstanding virtue as a mycologist was his very practical outlook. His opposition to academic views was sometimes carried to extremes, but he was intensely in earnest, and his enthusiasm in combating theory by practical experience often supplied a useful corrective. He helped to place plant pathology on a wider basis than that of parasitology, and in this his influence has been spread by his students to many parts of the Empire. As a teacher, he was the right man in the right place; to his students he was a friend, and he shared in their college life—he was a keen Rugger player—and gained their affection to an unusual degree.

E. J. B.

Lieut.-Colonel R. H. Elliot

LIEUT.-COLONEL ROBERT HENRY ELLIOT, whose death on November 9 we regret to record, had a distinguished career in ophthalmology as well as in other walks of life. The son of a colonel in the Army, he was educated at Bedford School and St. Bartholomew's Hospital, where he was a prizeman of the medical school. He had a brilliant career as a student and qualified M.B., B.S. (London) with honours in three subjects. He took his fellowship of the Royal College of Surgeons of England in 1892 and in the same year took the D.P.H. Cambridge and entered the Indian Medical Service. At Netley he was Montefiore scholar and medallist and Maclean prizeman in military surgery.

Soon after arrival in India, Elliot joined the Southern Presidency. His work there naturally led to an extended experience in ophthalmology, and he was superintendent of the Government Ophthalmic Hospital, Madras, and professor of ophthalmology in the Medical College from 1904 until 1914. While on leave in 1904, he completed his qualifications by obtaining the Sc.D. (Edin.) and the M.D. (Lond.).

Elliot's name will always be remembered for the work he did on sclero-corneal trephining in cases of glaucoma. The operation is known by his name all over the world, and was a notable advance in the surgical treatment of a disease the origin of which is in many cases obscure, and which has in the past led to a great deal of blindness.

Elliot's literary output was considerable. His chief works were handbooks on glaucoma and an account of sclero-corneal trephining, each of which went to a second edition. Besides this, he wrote an excellent text-book on tropical ophthalmology, which has been translated into a number of foreign languages, as well as smaller works. His work brought him many distinctions at home and abroad. Returning home in 1915, Elliot settled in London and quickly acquired a very large practice. For a number of years he was ophthalmic surgeon to the Prince of Wales General Hospital, Tottenham; and he was Consulting Ophthalmic Surgeon to the Hospital for Tropical Diseases.

Apart from his work as an ophthalmic surgeon, Elliot was an authority on snakes and a first-class amateur conjurer. His last book was published two years ago with the title "The Myth of the Mystic East". In it he discussed Indian magic and miraculous cures. He insisted that there was little if anything in Indian medicine that was unknown to European medicine; and he was equally sceptical as to the Indian rope trick, as may be seen from an article on "Indian Conjuring" contributed by him to NATURE of September 12 last.

Of late years, Col. Elliot had taken a prominent part in the management of the British Health Resorts Association, and until his health broke down he made his driving force felt in whatever he undertook. His wife died some years ago; much sympathy will be extended to his three sons.

We regret to announce the following deaths:

Captain H. J. Coningham, an authority on the geography of Asia Minor and the Caucasus, aged sixty-nine years.

Prof. Edwin O. Jordan, professor of bacteriology in the University of Chicago, known for his work on public health, on September 2, aged seventy years.

Prof. Oskar Klotz, professor of pathology and bacteriology in the University of Toronto, an authority on diseases of the arteries and the liver, on November 3, aged fifty-eight years.

Dr. Alfred Nippold, director of the Magnetic Observatory, Berlin, on October 4, aged sixty-two years.

News and Views

Rev. Wm. Tuckwell: a Pioneer of School Science

IN the first number of NATURE appeared an article by one of Huxley's friends, the Rev. Wm. Tuckwell, on "Science Teaching in Schools". Tuckwell was a pioneer in this work, and it was he who really first introduced a regular course of instruction amounting to no less than three hours per week per boy. The story of his career as headmaster of Taunton College School, now King's College, Taunton, is a long and interesting one. At first he met with extraordinary success, numbers of scholarships were won, and with the help of Henry Labouchere, Lord Taunton, and other influential friends the ancient school was moved to new quarters outside the town at a cost of £25,000. Then trouble arose owing to local clerical and conservative suspicion as to Tuckwell's orthodoxy; and after a furious controversy resignation was forced on him in 1877.

TUCKWELL was a man of wide culture, a good classical scholar, with a deep knowledge of English literature, and, although his work was apparently a failure, his methods were copied in schools all over the country. The school almost broke up when he left, but was later acquired by the Woodard Corporation and has since gradually risen in numbers to two hundred boarders. The pendulum has swung back again, and in 1934, Dr. R. D. Reid, a science graduate and the first layman for three hundred years, was appointed headmaster. He, wishing to recognize the work of his pioneering predecessor, sought out Mr. Tuckwell's surviving daughters, Lady Welsh, and Miss Gertrude Tuckwell, C.H. They have presented many of their father's books and MSS. to the school library, including a much treasured first copy of NATURE. They also have erected a memorial to him in the school chapel, and this will be dedicated by the Chaplain, Bishop O'Rorke, on November 29, at 6 p.m., at which service any friends would be welcomed. King's College possesses what is believed the first school laboratory, erected by Tuckwell in 1868. It is still in use, but is shortly to be demolished.

Wilhelm Ebstein

NOVEMBER 27 marks the hundredth anniversary of the birth of the eminent German physician Prof. Wilhelm Ebstein. He was born at Jauer, in Silesia, and studied medicine in Breslau and Berlin, where he was the pupil of Frerichs, Virchow and Romberg. After qualifying in 1859, he became physician to the All Saints Hospital at Breslau, where he did valuable work on gastric secretion and dermatology, a subject in which he always took a keen interest. He served as a medical officer in the Franco-Prussian War of 1870–71, and in 1874 was appointed professor of medicine and director of the Polyclinic at Göttingen, where he proved himself to be an indefatigable teacher, investigator and organizer, and created a model clinic well equipped with laboratories for scientific research. He was a remarkably prolific writer, as will be seen by the list of his works compiled by his son, the late medical historian Dr. Erich Ebstein (*Deut. Arch. Klin. Med.*, 89, 367; 1907), but he is best known for his studies on obesity, gout and diabetes. His book on diabetes and its treatment was translated into French, Danish, Swedish and Russian, and one on the nature and treatment of gout into English and French. His historical contributions included articles on the Plague of Thucydides, the English Sweat, medicine in the Bible, Linnæus as physician, and the history of chicken-pox. He retired from his chair in 1906 at the age of seventy years, but remained in active consulting practice until a few days before his death from apoplexy on October 12, 1912.

Relation of Science to War and Defence

AT a public meeting organized by the Association of Scientific Workers, held at the Royal College of Science, London, on November 19, questions relating to "Defence and the Responsibilities of the Scientist" were discussed by a representative gathering of scientific workers. Prof. J. B. S. Haldane presided, and Prof. S. Chapman and Air Commodore L. E. O. Charlton opened the discussion. Prof. Chapman denied the accusation that science is responsible for the horrors of war; dismissed the proposal that scientific workers should refuse to do war work as impracticable; urged them to join with the general public in order to take the necessary political action to stop the use of science for purposes of destruction, and suggested finally that the most suitable form of action would be the setting up of an international police force under the auspices of the League of Nations. Air Commodore Charlton showed how one of the principal technical achievements of our age, the aeroplane, has brought war to our doorstep, and has made the world population centres, such as London, the principal military objective in a future war. He presented quantitative evidence of the inadequacy of all known methods of defence, and urged scientific workers to devise something that would render the use of bombers impossible. In the subsequent discussion, attention was directed to the alternative policies advocated for avoiding war. The general consensus of opinion seemed to be in favour of some system of genuine collective security, and rejected both the isolationist and the pacifist solutions. J. D. Bernal reported the principal recommendations of the Science Section of the International Peace Conference held in Brussels last September. These included the proposal that scientific workers should apply scientific method to the study of war in all its aspects, to investigate the causes of war from the point of view of social and biological science, and to expose pseudo-scientific theories justifying war and racial superiority. It was finally proposed that a national commission representing all branches of science be set up to co-ordinate this work. These recommendations met with the warm support of the meeting.

Social Mission of Science

THE "Social Mission of Science", which formed the subject of a leading article in NATURE of October 24, has no more important objective, according to Prof. John Dewey, the veteran philosopher of Columbia University, than to elucidate the relation between authority and freedom. In his address at the Harvard Tercentenary Conference of Arts and Sciences on September 4 on "Authority and Resistance to Social Change" (*School and Society*, October 10), he exposed two fallacies underlying much of the philosophy that has gone by the name of liberalism, namely, that authority and freedom have separate and independent spheres of activity and no form of authority is justifiable that is not the product of, and sanctioned by, the conscious wants, efforts and satisfactions of individuals in their private capacity. While decrying the principle of authority, this philosophy, in fact, erected the wants and endeavours of private individuals seeking personal gain to the place of supreme authority in social life. Its failure to produce the conditions of a generally shared individual freedom is largely responsible for the recrudescence of the principle of authority in its most extreme and primitive form—the rise of dictatorships.

No collective planned economy, Prof. Dewey said, will succeed without some hitherto untried means for bringing into life an organic co-ordination of authority and freedom. It is here that science may help. It is suggested that the working of co-operative intelligence as displayed in science may serve as a working model of the union of freedom and authority. Here is seen individual freedom that is both supported by collective organized authority and, in turn, changes and is encouraged to change and develop by its own operation the authority upon which it depends. The extension to the wider field of human relations of the method of control by organized intelligence operating through the release of individual powers and capabilities presents enormous difficulties, but it is, Dewey holds, the only means whereby humanity can be rescued from "that futile and destructive oscillation between authoritative power and unregulated individual freedom to which we may justly attribute most of the sorrows and defeats of the past".

The Permanent International Studies Conference

THE report on the work of the Intellectual Co-operation Organisation, submitted by the Sixth Committee to the Assembly of the League of Nations, refers to the expansion of the Permanent International Studies Conference, which is now engaged in an objective and scientific study of foreign policy. This is an autonomous body which is able to pursue its work in the complete independence proper to scientific research. The most recent subjects dealt with by the Conference are State intervention in economic life, the possibility and conditions of an organization of collective security, and peaceful methods of change as applied to particular problems. For 1936 and 1937, the subjects chosen include the procedures for the peaceful settlement of disputes which have been applied in particular cases, over-population, colonies, migration and distribution of raw materials. In the field of education, an important result of the year's work of the Committee has been the publication by the Paris Institute of a first volume dealing with the organization of higher education and research in several European and American countries, while the Committee's efforts in the teaching of history are bearing fruit in the revision of text-books.

SPECIAL interest is attached to the attention which the International Committee is now giving to the question of unemployment among intellectual workers. While this question cannot be separated from the problem of unemployment as a whole, and the remedies to be recommended are chiefly national in character, international action may be of great value, particularly in the nature of co-operation between university information bureaux. Closer relations are being established between the Intellectual Co-operation Organisation and the International Council of Scientific Unions, and a permanent scientific committee is being set up as a result of the meeting of an expert committee to develop the Organisation's work in this field, and conversations on scientific subjects contemplated include the future of scientific research and of science in modern societies. In this field also the Institute of Intellectual Co-operation and the International Labour Office have undertaken an inquiry into the social consequences of progress in mechanization, and its effects on man and the circumstances in which he lives. Discussions on the main international systems governing authors' rights have led the Committee to conclude that amalgamation of the Berne Convention and the Pan-American Convention of Havana is not possible, and a new convention is being prepared with the object of reconciling the principles common to these Conventions and capable of forming the basis of a universal system of authors' rights.

Indian Science Abstracts

THE immense volume of original work now published necessitates a very complete system of abstracts, and the requirements of the individual sciences are now well served in this respect. Rarely, however, is an attempt made to abstract separately the scientific publications of any country, so that it is not possible to estimate its direct contributions to knowledge. Prior to the Great War, the now defunct Board of Scientific Advice published annually a résumé of the principal Indian scientific memoirs, and now, after the lapse of many years, the National Institute of Sciences in India has undertaken the much more difficult task of compiling an annual bibliography of science in India. This comprises not only the titles of all papers published by authors resident in India and of Indians working abroad, but also of papers dealing with problems specifically related to India. In the majority of cases, not only is the title of the paper given, but it is also followed by a brief, but adequate, abstract. To those who look upon India as a backward country this publication will come as a revelation, not merely from the volume of the work produced but also by the high standard to which much of it attains. In a country so predominantly agricultural it is gratifying to find that so much attention is being paid to biological subjects ; nearly one half of the abstracts come under the heads of botany, zoology and physiology, the latter including veterinary and medical subjects. As the general editor points out in his introduction, the present division of subjects, which is under nine main heads, is purely tentative and may require revision in the light of experience.

FUTURE historians of science are sure to find this publication invaluable, but we would suggest that the addition of an author index would facilitate reference. To the general editor, Dr. Baini Prashad, and to his associate editors, we would offer our congratulations, and we trust that the favourable reception which is sure to be accorded to these abstracts will encourage them to continue the issue of the bibliography. Further evidence of the great attention now being devoted to research in India is found also in the publication by the Inter-University Board, India, of a bibliography of the theses accepted for higher degrees in arts and science by the universities during the years 1930–35. By their system of external examiners, the Indian universities ensure that their higher degrees shall equal those of the Western universities, and this bibliography shows how active these young universities are as centres for the advancement of knowledge. It will go far to dispel the idea that they are merely examining bodies.

Post Office Tests of Inoculation against Colds

THE common catarrhal cold is responsible for much sickness disability, and preventive vaccines containing a mixture of the predominant microbes present in the secretions have been employed, the microbes being bacteria such as *M. catarrhalis*, *B. hofmanni*, Friedlander's bacillus, *Pneumococcus*, *Staphylococcus* and *Streptococcus*. Trials of such a vaccine in the past, some of them on a large scale, have been disappointing, occasionally seeming to be useful in individual cases, but not significantly so in any large groups. A further test by the Chief Medical Officer of the Post Office during the last three years upon a large scale has, it is announced, similarly been disappointing. Volunteers were invited from large towns, and some hundreds of them were inoculated in the autumn of the three years 1933–35, and their sickness rates over periods antedating the inoculations and during the treatment were compared. Comparisons were also made with large control groups in each place of uninoculated workers. About ten per cent of the volunteers—less than half the original number—who persisted throughout the three years of the experiment showed some improvement, but taken as a whole the results were not encouraging, for there was little reduction of sickness among the whole group compared with the control groups or with their previous record. The use of anti-catarrhal vaccine as a large-scale routine measure in the future is, therefore, not considered justifiable. The negative character of the results of this experiment is not unexpected, as the common cold is now regarded as being a virus disease, the bacterial organisms associated with it being of the nature of secondary invaders.

Civilization since James Watt

AT a dinner given by the Franklin Institute on January 21, 1936, to celebrate the two hundredth anniversary of the birth of James Watt, J. P. Boyd gave a thoughtful address, a résumé of which appears in the *Journal of the Franklin Institute* for September. He pointed out that while James Watt was still an infant, Saint-Pièrre had suggested that the attainment of knowledge and the subjugation of the material world to the requirements of human welfare would lead to a continual improvement in the lot of mankind. But the logic of academicians and the pamphleteering of philosophers could not compare in effectiveness with the work initiated by James Watt. The steam engine meant freedom from the limitations of time and space. England in 1750 contained seven million inhabitants, and was over-

NATURE

SUPPLEMENT

No. 3500 SATURDAY, NOVEMBER 28, 1936 Vol. 138

The Idea of a World Encyclopædia*

By H. G. Wells

MOST of the lectures that are given in this place to this audience are delivered by men of very special knowledge. They come here to tell you something you did not know before. But to-night I doubt if I shall tell you anything that is not already quite familiar to you. I am here not to impart facts but to make certain suggestions; and there is no other audience in the world to which I would make these suggestions more willingly and more hopefully than I do to you.

My particular line of country has always been generalization and synthesis. I dislike isolated events and disconnected details. I really hate statements, views, prejudices and beliefs that jump at you suddenly out of mid-air. I like my world as coherent and consistent as possible. So far at any rate my temperament is that of a scientific man. That is why I have spent a few score thousand hours of my particular allotment of vitality in making outlines of history, short histories of the world, general accounts of the science of life, attempts to bring economic, financial and social life into one conspectus and even, still more desperate, struggles to estimate the possible consequences of this or that set of operating causes upon the future of mankind.

All these attempts had profound and conspicuous faults and weaknesses; even my friends are apt to mention them with an apologetic smile. Presumptuous and preposterous they were, I admit, but I look back upon them, completely unabashed. Somebody had to break the ice. Somebody had to try out such summaries on the general mind. My reply to the superior critic has always been—forgive me—"Damn you, do it better".

The least satisfactory thing about these experiments of mine, so far as I am concerned, is that they did not at once provoke the learned and competent to produce superior substitutes. And in view of the number of able and distinguished people we have in the world professing and teaching economic, sociological, financial science, and the admittedly unsatisfactory nature of the world's financial, economic and political affairs, it is to me an immensely disconcerting fact that the "Work, Wealth and Happiness of Mankind" which was first published in 1932 remains—practically uncriticized, unstudied and largely unread—the only attempt to bring human ecology into one correlated survey.

Well; I mention this experimental work now in order that you should not think I am just throwing casually formed ideas before you to-night. I am bringing you my very best. The thoughts I am setting out here have troubled my mind, for years, and my ideas have been slowly gathering definition throughout these experiments and experiences. They have interwoven more and more intimately with other solicitudes of a more general nature in which I feel fairly certain of meeting your understanding and sympathy.

I doubt if there is anybody here to-night who has not given a certain amount of anxious thought to the conspicuous ineffectiveness of modern knowledge and—how shall I call it?—trained and studied thought in contemporary affairs. I think that it is mainly in the troubled years since 1914 that the world of cultivated, learned and scientific people, of which you are so representative, has become conscious of this ineffectiveness. Before that time, or to be more precise before 1909 or 1910, the world, our world as we older ones recall it, was living in a state of confidence, of established values, of assured security, which is already becoming now almost incredible. We had no suspicion then how much that apparent security had been undermined by science, invention and sceptical inquiry. Most of us carried on into the War and even right through the War under the inertia of the accepted beliefs to which we had been born. We felt that the sort of history we were used to was still going on, and we did not realize at all that the War was a new sort of thing, not like the old wars, that the old traditions of strategy were disastrously out of date and that the old pattern of settling up after a war could only lead to such a thickening tangle of evil consequences as we contemplate to-day.

---

* Friday Evening Discourse delivered at the Royal Institution on November 20.

We know better now. Wiser after the events as we all are, few of us now fail to appreciate the stupendous ignorance, the almost total lack of grasp of social and economic realities, the short views, the shallowness of mind, that characterized the treaty-making of 1919 and 1920. I suppose Mr. Maynard Keynes was one of the first to open our eyes to this world-wide intellectual insufficiency. What his book, "The Economic Consequences of the Peace", practically said to the world was this: These people, these politicians, these statesmen, these directive people who are in authority over us, know scarcely anything about the business they have in hand. Nobody knows very much, but the important thing to realize is that they do not even know what is to be known. They arrange so and so, and so and so must ensue and they cannot or will not see that so and so must ensue. They are so unaccustomed to competent thought, so ignorant that there is knowledge and of what knowledge is, that they do not understand that it matters.

The same terrifying sense of insufficient mental equipment was dawning upon some of us who watched the birth of the League of Nations. Reluctantly and with something like horror, we realized that these people who were, they imagined, turning over a new page and beginning a fresh chapter in human history, knew collectively scarcely anything about the formative forces of history. Collectively, I say. Altogether they had a very considerable amount of knowledge, unco-ordinated bits of quite good knowledge, some about this period and some about that, but they had no common understanding whatever of the processes in which they were obliged to mingle and interfere. Possibly all the knowledge and all the directive ideas needed to establish a wise and stable settlement of the world's affairs in 1919 existed in bits and fragments, here and there, but practically nothing had been assembled, practically nothing had been thought out, nothing practically had been done to draw that knowledge and these ideas together into a comprehensive conception of the world. I put it to you that the Peace Conference at Versailles did not use anything but a very small fraction of the political and economic wisdom that already existed in human brains at that time; and I put it to you as rational creatures that if usage had not dulled our apprehension to this state of affairs, we should regard this as fantastically absurd.

If I might attempt a sweeping generalization about the general course of human history in the eighteen years that have followed the War, I believe I should have you with me if I described it as a series of flounderings, violent ill-directed mass-movements, slack drifting here and convulsive action there. We talk about the dignity of history. It is a bookish phrase for which I have the extremist disrespect. There is no dignity yet in human history. It would be pure comedy, if it were not so often tragic, so frequently dismal, generally dishonourable and occasionally quite horrible; and it is so largely tragic because the human animal really is intelligent, can feel finely and acutely, expresses itself poignantly in art, music and literature, and—this is what I am driving at—impotently knows better.

Consider only the case of America during this recent period. America, when all is said and done, is one of the most intelligently *aware* communities in the world. Quite a number of people over there seem almost to know what is happening to them. Remember first the phase of fatuous self-sufficiency, the period of unprecedented prosperity, the boom, the crisis, the slump and the dismay. And then appeared the new President, Franklin Roosevelt, and from the point of view of the present discussion he is one of the most interesting figures in all history. Because he really did make an appeal for such knowledge and understanding as existed to come to his aid. America in an astounding state of meekness was ready to be told and shown. There were the universities, great schools, galaxies of authorities, learned men, experts, teachers, doctors, professors, gowned, adorned and splendid. Out of this knowledge mass there has since come many very trenchant criticisms of the President's mistakes. But at the time this—what shall I call it—this higher brain, this cerebrum, this grey matter of America was so entirely unco-ordinated that it had nothing really comprehensive, searching, thought-out and trustworthy for him to go upon. The President had to experiment and attempt this and that, he turned from one promising adviser to another, because there was nothing ready for him. He did not pretend to be a divinity. He was a politician—of exceptional good-will. He was none of your dictator gods. He showed himself extremely open and receptive for the organized information and guidance . . . *that wasn't there.* And it isn't there now.

Some years ago there was a considerable fuss in the world about preparedness and unpreparedness. Most of that clamour concerned the possibility of war. But here was a case of most fantastic unpreparedness on the part of hundreds of eminent men, who were supposed to have studied them, for the normal development of a community in times of peace. There had been no attempt to assemble that mechanism of knowledge of which America stood in need.

I repeat that if usage had not dulled us into a habit of acquiescence with this sort of thing we should think our species collectively insane to go about its business in this haphazard, planless, negligent fashion.

I think I have said enough to recall to anyone here who may have lapsed from the keen apprehension of his first realization, of this wide gap between what I may call the at present unassembled and unexploited best thought and knowledge in the world and the ideas and acts not simply of the masses of common people, but of those who direct public affairs, the dictators, the leaders, the politicians, the newspaper directors, and our spiritual guides and teachers. We live in a world of unused and misapplied knowledge and skill. That is my case. Knowledge and thought are ineffective. The human species regarded as a whole is extraordinarily like a man of the highest order of brain, who through some lesions or defects or insufficiencies of his lower centres, suffers from the wildest uncoordinations, St. Vitus's dance, agraphia, aphonia, and suffers dreadfully (knowing better all the time) from the silly and disastrous gestures he makes and the foolish things he says and does.

I don't think this has ever been so evident as it is now. I doubt if in the past the gap was so wide as it is now between the occasions that confront us, and the knowledge we have assembled to meet them. But because of a certain run of luck in the late nineteenth century, the existence of that widening gap and the menace of that widening gap were not thrust upon our attention as they have been since the War.

At first that realization of the ineffectiveness of our best thought and knowledge struck only a few people, Mr. Maynard Keynes for example, who were in what I may call salient positions, but gradually I have noted the realization spreading and growing. It takes various forms. Prominent men of science speak more and more frequently of the responsibility of science for the disorder of the world. And if you are familiar with that most admirable of all newspapers, NATURE, and if you care to turn over the files of that very representative weekly for the past quarter of a century or so and sample the articles, you will observe a very remarkable change of note and scope in what it has to say to its readers. Time was when NATURE was almost pedantically special and scientific. Its detachment from politics and general affairs was complete. But latterly the concussions of the social earthquake and the vibration of the guns have become increasingly perceptible in the laboratories. NATURE from being specialist has become world-conscious, so that now it is almost haunted week by week by the question: "What are we to do before it is too late, to make what we know and our way of thinking effective in world affairs?"

In that I think it is expressing a change which is happening in the minds of—if I may presume to class myself with you—nearly all people of the sort which fills this theatre to-night.

And consider again the topics that have been dealt with at the latest gathering of the British Association. The very title of the presidential address: "The Impact of Science upon Society"! Sir Josiah Stamp, as you will remember, stressed the need of extending endowment and multiplying workers in the social sciences. Professor Philip dealt with "The Training of the Chemist for the Service of the Community". Professor Cramp talked of "The Engineer and the Nation", and there was an important discussion of "The Cultural and Social Values of Science" in which Sir Richard Gregory, Professor Hogben and Sir Daniel Hall said some memorable things. There can be no doubt of the reality of this awakening of the scientific worker to the necessity of his becoming a definitely *organized* factor in the social scheme of the years before us.

Well, so far I have been merely opening up my subject and stating the problem for consideration. We want the intellectual worker to become a more definitely organized factor in the human scheme. How is that factor to be organized? Is there any way of implementing knowledge for ready and universal effect? I ask you to examine the question whether this great and growing gap between special knowledge and thought and the common ideas and motives of mankind can be bridged, and if so how it can be bridged.

Can scientific knowledge and specialized thought be brought into more effective relation to general affairs? Let us consider first what is actually going on. I find among my scientific and specialist friends a certain disposition—and I think it is a mistaken disposition—for direct political action and special political representation. The scientific and literary workers of the days when I was a young man were either indifferent or conservative in politics; nowadays quite a large proportion of them are inclined to active participation in extremist movements; many are leftish and revolutionary, some accept the strange pseudo-scientific dogmas of the communist party though that does no credit to their critical training, and even those who are not out on the left are restless for some way of intervening, definitely as a class, in the general happenings of the community. Their ideas of possible action vary from important-looking signed pronouncements and protests to a sort of strike against war, the withholding of services and the refusal to assist in technical developments that may be misapplied. Some favour the idea of a gradual supersession of the political forms and methods of mass democracy by government through some sort of *élite* in which the man of science and the technician will play a dominating part. There are very large vague patches upon this idea but the general projection is in the form of a sort of modern priesthood, an oligarchy of professors and exceptionally competent people. Like Plato they would make the philosopher king. This project involves certain assumptions about the general quality and superiority of the intellectual worker that I am afraid will not stand scrutiny.

I submit that sort of thing—political activities, party intervention and dreams of an authoritative *élite*—is not the way in which specialists, artists and specialized thinkers and workers who constitute the vital feeling and understanding of the body politic can be brought into a conscious, effective, guiding and directive relationship to the control of human affairs. Because—I hope you will acquit me of any disrespect for science and philosophy when I say this—we have to face the fact that from the point of view of general living, men of science, artists, philosophers, specialized intelligences of any sort, do not constitute an *élite* that can be mobilized for collective action. They are an extraordinarily miscellaneous assembly, and their most remarkable common quality is the quality of concentration in comparative retirement —each along his own line. They have none of the solidarity, the customary *savoir faire*, the habits arising out of practices, activities and interests in common, that lawyers, doctors or any of the really socially organized professions for example display. A professor-ridden world might prove as unsatisfactory under the stress of modern life and fluctuating conditions as a theologian-ridden world.

A distinguished specialist is precious because of his cultivated gift. It does not follow at all that by the standards of all-round necessity he is a superior person. Indeed by the very fact of his specialization he may be less practised and competent than the average man. He probably does not read his newspaper so earnestly, he finds much of the common round a bother and a distraction and he puts it out of his mind. I think we should get the very gist of this problem if we could compare twelve miscellaneous men of science and special skill, with twelve unspecialized men taken —let us say—from the head clerk's morning train to the city. We should probably find that for commonplace teamwork and the ordinary demands and sudden urgencies of life, the second dozen was individually quite as good as if not better than the first dozen. In a burning hotel or cast away on a desert island they would probably do quite as well. Yet collectively they would be ill-informed and limited men ; the whole dozen of them would have nothing much more to tell you than any one of them. On the other hand, our dozen specialists would each have something distinctive to tell you. The former group would be almost as uniform in their knowledge and ability as tiles on a roof, the latter would be like pieces from a complicated jig-saw puzzle. The more you got them together the more they would signify. Twelve clerks or a hundred clerks ; it wouldn't matter ; you would get nothing but dull repetitions, and a flat acquiescent suggestible outlook upon life. But every specialized man we added would be adding something to the directive pattern of life. I think that consideration takes us a step further in defining our problem to-night.

It is *science* and not *men of science* that we want to enlighten and animate our politics and rule the world.

Now I will take rather a stride forward in my argument. I will introduce a phrase, *New Encyclopædism*, which I shall spend most of the rest of my time defining. I want to suggest that something—a new social organ, a new institution, which for a time I shall call *World Encyclopædia* is the means whereby we can solve the problem of that jig-saw puzzle and bring all the scattered and ineffective mental wealth of our world into something like a common understanding and into effective reaction upon our vulgar everyday political, social and economic life. I warn you that I am flinging moderation to the winds in the suggestions I am about to put before you. They are immense suggestions. I am sketching what is really a scheme for the reorganization and reorientation of education and information throughout the world. No less. We are so accustomed to the existing schools, colleges, universities, research organizations of the world ; they have so moulded and made us and trained us from our earliest years to respect and believe in them ; that it is with a real feeling of temerity, of alma-matricidal impiety, so to speak, that I have allowed my mind to explore their merits and question whether they were not now altogether an extraordinarily loose, weak and out-of-date miscellany. Yet I do not see how we can admit, and I am disposed to think you have admitted with me, the existence of this terrifying gap between available knowledge and current social and political events, and not go on to something like an indictment of this whole great world of academic erudition, training and instruction from China to Peru—an indictment for, at least, inadequacy and inco-ordination if not for actual negligence. It may be only a temporary inadequacy, a pause in development before renascence, but inadequate altogether they are. Universities have multiplied greatly, yes, but they have failed to participate in the general advance in power, scope and efficiency that has occurred in the past century. In transport we have progressed from coaches and horses by way of trains to electric traction, motor-cars and aeroplanes. In mental organization we have, so to speak, simply multiplied our coaches and horses and livery stables.

Let me now try to picture for you this missing element in the modern human social mechanism, this needed connexion between the percipient and informative parts and the power organization for which I am using this phrase, World Encyclopædia. And I will take it first from the point of view of the ordinary educated citizen—for in a completely modernized state every ordinary citizen will be an educated citizen. I will ask you to imagine how this World Encyclopædic organization would enter into his life and how it would affect him. From his point of view the World Encyclopædia would be a row of volumes in his own home or in some neighbouring house or in a convenient public library or in any school or college, and in this row of volumes he would, without any great toil or difficulty, find in clear understandable language, and kept up to date, the ruling concepts of our social order, the outlines and main particulars in all fields of knowledge, an exact and reasonably detailed picture of our universe, a general history of the world, and if by any chance he wanted to pursue a question into its ultimate detail, a trustworthy and complete system of reference to primary sources of knowledge In fields where wide varieties of method and opinion existed, he would find, not casual summaries of opinions, but very carefully chosen and correlated statements and arguments. I do not image the major subjects as being dealt with in special articles rather hastily written, such as has been the tradition of encyclopædias since the days of Diderot's heroic effort. Our present circumstances are altogether different from his. Nowadays there is an immense literature of statement and explanation scattered through tens of thousands of books, pamphlets and papers, and it is not necessary, it is undesirable, to trust to such hurried summaries as the old tradition was obliged to make for its use. The day when an energetic journalist could gather together a few star contributors and a miscellany of compilers of very uneven quality to scribble special articles for him, articles often tainted with propaganda and advertisement, and call it an encyclopædia, is past. The modern World Encyclopædia should consist of selections, extracts, quotations, very carefully assembled with the approval of outstanding authorities in each subject, carefully collated and edited and critically presented. It would be not a miscellany, but a concentration, a clarification and a synthesis.

This World Encyclopædia should be the mental background of every intelligent man in the world. It should be alive and growing and changing continually under revision, extension and replacement from the original thinkers in the world everywhere. Every university and research institution should be feeding it. Every fresh mind should be brought into contact with its standing editorial organization. On the other hand its contents would be the standard source of material for the instructional side of school and college work, for the verification of facts and the testing of statements—everywhere in the world. Even journalists would deign to use it; even newspaper proprietors might be made to respect it. Such an encyclopædia would play the role of an undogmatic Bible to a world culture. It would do just what our scattered and disoriented intellectual organizations of to-day fall short of doing. It would hold the world together mentally.

It may be objected that this is a Utopian dream. This is something too great to achieve, too good to be true. I won't deal with that for a few minutes. Flying was a Utopian dream, a third of a century ago. What I am putting before you is a perfectly sane, sound and practical proposal. But first I will notice briefly two objections—obstructions rather than objections—that one will certainly encounter at this point.

One of these is not likely to appear in any great force in this gathering. You have all heard and you have all probably been irritated or bored by the assertion that no two people think alike "*quot homines, tot sententiæ*", that science is always contradicting itself, that economists like theologians can never agree. It is largely mental laziness on the defensive that makes people say this kind of thing. They don't want their intimate convictions turned over and examined, and it is unfortunate that the emphasis put upon minor differences by men of science, and belief in their strenuous search for the completest truth and the exactest expression sometimes give colour to this sort of misunderstanding. But I am inclined to think that most people overrate the apparent differences in the world of opinion to-day. Even in theology a psychological analysis reduces many flat contradictions to differences in terminology. My impression is that human brains are very much of a pattern, that under the same conditions they react in the same way, and that were it not for tradition, upbringing, accidents of circumstance and particularly of accidental individual obsessions, we should find ourselves—since we all face the same universe—much more in agreement than is superficially apparent. We speak different languages and dialects of thought and can even at times catch ourselves flatly contradicting each other in words while we are doing our utmost to express the same idea. And self love and personal vanity are not excluded from the intellectual life. How often do we see men misrepresenting each other in order to exaggerate a difference and secure the gratification of an argumentive victory! A World Encyclopædia as I conceive it would bring together into close juxtaposition and under critical scrutiny many apparently conflicting systems of statement. It might act not merely as an assembly of fact and statement, but as an organ of adjustment and adjudication, a clearing house of misunderstandings; it would be deliberately a synthesis, and so act as a flux and a filter for a very great quantity of human misapprehension. It would *compel* men to come to terms with one another. I think it would relegate "*quot homines, tot sententiæ*" back to the Latin comedy from which it emerged.

The second type of obstruction that this idea of a World Encyclopædia will encounter is even less likely to find many representatives in the present gathering and I will give it only the briefest of attention. (You know that kind of neuralgic expression, the high protesting voice, the fluttering gesture of the hands.) "But you want to *stereotype* people. What a dreadful, dreadful world it will be when everybody thinks alike"—and so they go on. Most of these elegant people who want the world picturesquely at sixes and sevens are hopeless cases, but for the milder instances it may be worth while remarking that it really does not enhance the natural variety and beauty of life to have all the clocks in a town keeping individual times of their own, no charts of the sea, no time-tables, but trains starting secretly to unspecified destinations, infectious diseases without notification and postmen calling occasionally when they can get by the picturesque footpads at the corner. I like order in the place of vermin, I prefer a garden to a swamp and the whole various world to a hole-and-corner life in some obscure community, and to-night I like to imagine I am making my appeal to hearers of a kindred disposition to my own.

Next let us take this World Encyclopædia from the point of view of the specialist and the super-intellectual. To him even more than to the common intelligent man World Encyclopædia is going to be of value because it is going to afford him an intelligible statement of what is being done by workers parallel with himself. Further, it will be giving him the general statement of his own subject that is being made to the world at large. He can watch that closely. On the assumption that the World Encyclopædia is based on a world-wide organization he will be—if he is a worker of any standing—a corresponding associate of the Encyclopædia organization. He will be able to criticize the presentation of his subject, to suggest amendments and restatements. For a World Encyclopædia that was kept alive and up to date by the frequent re-issue of its volumes, could be made the basis of much fundamental discussion and controversy. It might breed swarms of pamphlets, and very wholesome swarms. It would give the specialist just that contact with the world at large which at present is merely caricatured by his more or less elementary class-teaching, amateurish examination work and college administration. In my dream of a World Encyclopædia I have a feeling that part of the scheme would be the replacement of the latter group of professorial activities, the college business, tutoring, normal lecturing work and so on, by a new set of activities, the encyclopædic work, the watching brief to prevent the corruption of the popular mind. In enlightening the general mind the specialist will broaden himself. He will be redeemed from oddity, from shy preciousness and practical futility.

Well, you begin to see the shape of this project; and you will realize that, except in so far as the nature of its reaction upon the world's affairs is concerned, it is far away from anything like the valiant enterprise of Denis Diderot and his associates a century and a half ago. That extraordinary adventure in intellectual synthesis makes this dream credible. That is our chief connexion with it.

And here I have to make an incidental disavowal. I want to make it clear how little I have to do with what I am discussing. In order to get some talk going upon this idea of an Encyclopædia, I have been circulating a short memorandum upon the subject among a number of friends. I did not think to mark it *Private*, and unhappily one copy seems to have fallen into the hands of one of those minor pests of our time, a personal journalist, who at once rushed into print with the announcement that I was proposing to *write* a brand new Encyclopædia, all with my own little hand out of my own little head. At the age of seventy! Once a thing of this sort is started there is no stopping it—and I admit that announcement enables you to put me in my place in a pleasantly ridiculous light. But I think after what I have put before you now that you will acquit me of any such colossal ambition. I implore you not to let that touch of personal absurdity so difficult to avoid altogether belittle the greatness and urgency of the cause I am pleading. This Encyclopædia I am thinking of is something in which manifestly I have neither the equipment nor the quality to play any but an infinitesimal part. I am asking for it in the role of a common intelligent man who needs it and understands the need for it, both for himself and his world. After that you can leave me out of it. It is just because in the past I *have* had some experience in the assembling of outlines of knowledge for popular use, that I realize, perhaps better than most people, the ineffectiveness of this sort of effort on the part of individuals or small groups. It is something that must be taken up—and taken up very widely and seriously—by the universities, the learned societies, the responsible educational organizations if it is to be brought into effective being. It is a super university I am thinking of, a world brain; no less. It is nothing in the nature of a supplementary enterprise. It is a completion necessary to modernize the university idea.

That brings me to the last part of this speculation. Can such an Encyclopædia as I have been suggesting to you, be a possible thing? How can it be set going? How can it be organized and paid for? I agree I have now to show it as a possible thing. For I am going to make the large assumption that you think that *if it is a possible thing* it is a desirable thing. How are we to set about it?

I think something in this way: To begin with we want a promotion organization. We want, shall I call it, an Encyclopædia Society to ask for an Encyclopædia and to get as many people as possible asking for an Encyclopædia. Directly that society asks for an Encyclopædia it will probably have to resort to precautionary measures against any enterprising publisher who may see in that demand a chance for selling some sort of vamped-up miscellany as the thing required, and who may even trust to the unworldliness of conspicuous learned men for some sort of countenance for his raid.

Next this society of promoters will have to survey the available material. For most of the material for a modern Encyclopædia exists already—though in a state of impotent diffusion. In all the various departments with which an Encyclopædia should deal, groups of authoritative men might be induced to prepare a comprehensive list of primary and leading books, articles, statements which taken together would give the best, clearest and most quintessential renderings of what is known and thought within their departments. This would make a sort of key bibliography to the thought and knowledge of the world. My friend Sir Richard Gregory has suggested that such a key bibliography for a World Encyclopædia would in itself be a very worthwhile thing to evoke. I agree with him. I haven't an idea what we should get. I imagine something on the scale of ten or twenty thousand items. I don't know.

Possibly our Encyclopædia Society would find that such a key bibliography was in itself a not unprofitable undertaking, but that is a comment by the way.

The next step on from this key bibliography would be the organization of a general editorial board and of departmental boards dealing with separate fields of interest. These boards would be permanent bodies—for a World Encyclopædia must have a perennial life. We should have to secure premises, engage a literary staff and, with the constant co-operation of the departmental groups, set about the task of making our great synthesis and abstract. I must repeat that for the purposes of a World Encyclopædia probably we would not want much original writing. If a thing has been stated clearly and compactly once for all, why paraphrase it or ask some inferior hand to restate it? Our job may be rather to secure the use of copyrights and induce leading exponents of this or that field of science or criticism to co-operate in the selection, condensation, expansion or simplification of what they have already said so well.

Now I will ask you to take another step forward and imagine our World Encyclopædia has been assembled and digested and that the first edition is through the press. So far we shall have been spending money upon this great enterprise and receiving nothing; we shall have been spending capital, for which I have at present not accounted. I will merely say that I see no reason why the capital needed for these promotion activities should not be forthcoming. This is no gainful enterprise, but you have to remember that the values we should create would be far more stable than the ephemeral encyclopædias representing sums round about a million pounds or so which have hitherto been the high-water mark of encyclopædic enterprise. These were essentially book-selling enterprises made to exploit a demand. But this World Encyclopædia as I conceive it, if only because it will have roped in the larger part of the original sources of exposition, discussion and information, will be in effect a world monopoly, and it will be able to levy and distribute direct and indirect revenue, on a scale quite beyond the resources of any private publishing enterprise. I do not see that the financial aspects of this huge enterprise, big though the sums involved may be, present any insurmountable difficulties in the way of its realization. The major difficulty will be to persuade the extremely various preoccupied, impatient and individualistic scholars, thinkers, scientific workers and merely distinguished but unavoidable men on whose participation its success depends, of its practicability, convenience and desirability.

So far as the promotion of it goes I am reasonably hopeful. Quite a few convinced, energetic and resourceful people could set this ball rolling towards realization. To begin with, it is not necessary to convert the whole world of learning, research and teaching. I see no reason why at any stage it should encounter much positive opposition. Negative opposition—the refusal to have anything to do with it and so forth—can be worn down by persistence and the gathering promise of success. A World Encyclopædia has not to fight adversaries or win majorities before it gets going; and once this ball is fairly set rolling it will be very hard to stop. A great danger, as I have already suggested, will come from attempts at the private mercenary exploitation of this world-wide need—the raids of popular publishers and heavily financed salesmen, and in particular attempts to create copyright difficulties and so to corner the services and prestige of this or that unwary eminent person by anticipatory agreements. *Vis-à-vis* with salesmanship the man of science, the man of the intellectual *élite*, is apt to show himself a very Simple Simon indeed. And of course from the very start, various opinionated cults and propagandas will be doing their best to capture or buy the movement. Well, it mustn't be captured or bought, and in particular its silence must not be bought or captured. That danger may in the end prove to be a stimulus. It may be possible in some cases to digest and assimilate special cults to their own and the general advantage.

There will also be a constant danger that some of the early promoters may feel and attempt to realize a sort of proprietorship in the organization, to make a group or a gang of it. But to recognize that danger is half way to averting it.

I have said nothing so far about the language in which the Encyclopædia should appear. It is a question I have not worked out. But I think that the main text should be in one single language, from which translations in whole or part could be made. Catholic Christianity during the years of its greatest influence was held together by Latin, and I do not think that I am giving way to any patriotic bias when I suggest that unless we contemplate a polyglot publication—and never yet have I heard of a successful polyglot publication —*English*, because it has a wider range than German, a greater abundance and greater subtlety of expression than French and more precision than Russian, is the language in which the original text of a World Encyclopædia ought to stand. Moreover, it is in the English-speaking communities that such an enterprise as this is likely to find the broadest basis for operations, the frankest criticism and the greatest freedom from official interference and government propaganda. But that must not hinder us from drawing help and contributions from and contemplating a use in every community in the world.

So far I have laid no stress upon the immense advantage this enterprise would have in its detachment from immediate politics. Ultimately if our dream is realized it must exert a very great influence upon everyone who controls administrations, makes wars, directs mass behaviour, feeds, moves, starves and kills populations. But it does not immediately challenge these active people It is not the sort of thing to which they would be directly antagonist. It is not ostensibly anti-*them*. They would not easily realize its significance for all that they do and are. The prowling beast will fight savagely if it is pursued and challenged upon the jungle path in the darkness, but it goes home automatically as the day breaks.

You see how such an Encyclopædic organization could spread like a nervous network, a system of mental control about the globe, knitting all the intellectual workers of the world through a common interest and a common medium of expression into a more and more conscious co-operating unity with a growing sense of their own dignity and responsibility, informing without pressure or propaganda, directing without tyranny. It could be developed wherever conditions were favourable ; it could make inessential concessions and bide its time in regions of exceptional violence, grow vigorously again with every return to liberalism and reason.

So I sketch my suggestion for a rehabitation of thought and learning that ultimately may release a new form of power in the world, recalling indeed the power and influence of the Churches and religions of the past but with a progressive, adaptable and recuperative quality that none of these possessed. I believe that in some such way as I have sketched, the mental forces now largely and regrettably scattered and immobilized in the universities, the learned societies, research institutions and technical workers of the world, could be drawn together into a real directive world intelligence, and by the mere linking and implementing of what is known, human life as a whole could be made much surer, stronger, bolder and happier than it has ever been up to the present time. Until something of this sort is done, I do not see how the common life can ever be raised except occasionally, locally and by a conspiracy of happy chances, above its present level of impulsiveness, insincerity, insecurity, general under-vitality, under-nourishment and aimlessness. For that reason I think the promotion of an organization for a World Encyclopædia may prove in the long run to be a better investment for the time and energy of intelligent men and women than any definite revolutionary movement, Socialism, Communism, Fascism, Imperialism, Pacificism or any other of the current *isms* into which we pour ourselves and our resources so freely. None of these movements has anything like the intellectual comprehensiveness needed to construct the world anew.

Let me be very clear upon one point. I am not saying that a World Encyclopædia will in itself solve any single one of the vast problems that must be solved if man is to escape from his present dangers and distresses and enter upon a more hopeful phase of history ; what I am saying—and saying with the utmost conviction—is this, that without a World Encyclopædia to hold men's minds together in something like a common interpretation of reality, there is no hope whatever of anything but an accidental and transitory alleviation to any of our world troubles. As mankind is, so it will remain, until it pulls its mind together. And if it does not pull its mind together then I do not see how it can help but decline. Never was a living species more perilously poised than ours at the present time. If it does not take thought to end its present mental indecisiveness catastrophe lies ahead. Our species may yet end its strange eventful history as just the last, the cleverest, of the great apes. The great ape that was clever—but not clever enough. It could escape from most things but not from its own mental confusion and the destruction that is the inevitable consequence of incurable mental confusion.

PRINTED IN GREAT BRITAIN BY FISHER, KNIGHT AND CO., LTD , ST. ALBANS

crowded. Now great masses of people can concentrate in towns secure in the promise of food, shelter and clothing. In 1936 the population of London is as great as that of all England a hundred years ago. The materials required for human life in crowded centres are obtained by the steam engine. Science and engineering accelerated the growth of the 'empire of the machine'. Men everywhere, although freed from the soil, feel themselves enslaved to the machine. To-day, four of the largest modern turbines have an energy capacity greater than that of the entire adult working population of the United States.

MANKIND now appears to be on the eve of a third industrial revolution. We have machines watched and directed by other machines. As an example, consider the photo-electric cell, which never makes a mistake and never knows fatigue. It is used for many and varied purposes. It sorts vegetables, fruit and eggs, it measures illumination, appraises colours, classifies minerals, counts bills and throws out counterfeits. It times races, counts people and vehicles, records smoke in tunnels, directs traffic automatically and substitutes a new process for photo-engraving. Automatically controlled machinery for making lamp bulbs at Corning, New York, produces 650 thousand bulbs per machine per day, which is ten thousand times more than that produced by the methods previously employed. Remarkable progress in material culture has been witnessed during the last hundred years; but institutions, social customs and thought patterns have, as always, lagged behind. Saint Pièrre's idea of progress is beginning to be challenged; some social pessimists are substituting the notion of change for that of progress. To establish control over the gigantic material gains and to cope with the resultant problems are the challenges facing mankind to-day. Many years may be required to solve them, but surely that intelligence which has performed such marvellous feats in material matters will find an avenue for social progress.

The Newcomen Society

AT a meeting of the Newcomen Society held at the Iron and Steel Institute on November 18, the report of the Council for the session 1935–36 was presented. This showed that the activities of the Society have been well maintained and that the total membership is now 424 as compared with 343 a year ago. There has been a considerable increase in the membership in America. Fourteen papers were read during the session and the Society has published as an extra publication the "Collected Papers" of Mr. Rhys Jenkins, one of the founders of the Society. Mr. W. J. Tennant was elected president for the ensuing year. After the passing of the report and accounts, a paper was read by Dr J. Thomas on "Josiah Wedgwood as a Pioneer of Steam Power in the Pottery Industry". By searching the Boulton and Watt papers at the Public Library and the Assay Office at Birmingham, Dr. Thomas has brought to light new material relating to the introduction of the Watt rotative steam engine into industry in the Midlands, and he has come to the conclusion that the earliest of such engines installed in a factory was that supplied to Wedgwood and erected at Etruria in 1782. Wedgwood's faith in the steam engine was shown by the financial assistance he gave to Boulton at a critical time. Like Priestley, Erasmus Darwin, Keir, Boulton, Watt and others, Wedgwood was a member of the famous Lunar Society, and his scientific leanings were shown in many ways. Towards the close of his paper, Dr. Thomas was able to show by a series of lantern slides how Watt used the medallions and casts of Wedgwood when in his retirement he devoted his time to the construction of the two statuary reproducing machines now preserved in Watt's garret workshop at the Science Museum. There can be little doubt that Watt's work in this direction was largely due to his friendship with Wedgwood.

New Tube Trains in London

EXPERIMENTS have recently been made on the first of four six-car tube trains manufactured by the Metropolitan–Cammell Carriage and Wagon Co., Ltd. for the London Passenger Transport Board. The train is composed of three two-car units, each car having the whole of the electric equipment under the floor. This avoids the necessity of a switch compartment, and so the new six-car train has approximately the same sitting accommodation as the existing seven-car train. The acceleration has been increased to two miles per hour per second and the braking rate (deceleration) to three miles per hour per second. The increased power has been gained partly by driving directly fifty per cent of the axles and by arranging so that more of the weight of the train is available for cohesion. The total horse-power of the new trains will be 1,650, as compared with 960 for the existing six-car trains. Several firms have suggested various schemes for operating the trains, but the following features are common to them all. All the control is operated at 50 volts and each car is separate and complete. Resistance switches are never called upon to brake under load. Each of the bogies is of all-welded construction and each carries one traction motor on the inside axle. This arrangement provides 58 per cent of the available weight of the car for adhesion. Three of the trains are streamlined at the driving end. The driver's seat is in the centre of the cab, with the master controller and braking controller on either side. The air-operated sliding doors are electrically controlled. Particulars with photographs are given in the *Electrical Review* of November 20.

Steamship Communication between Europe and America

In the *Metropolitan Vickers Gazette* of October, Mr. Leivesley continues his papers on notable ships and their equipment. He points out that it is now ninety-six years since a regular steamship communication was inaugurated between Europe and America. This was first established by the Cunard S.S. *Britannia* in July 1840, which crossed from Liverpool to Boston via Halifax in 14¼ days. She was equipped with steam engines driving paddle wheels, and her average speed was 8½ knots. Since then, the speed of the steamers has increased uniformly up to the present when it is 30 knots. The tonnage of the *Britannia* was 1,154 and her length was 207 ft. The tonnage of the *Queen Mary* is 80,773 and her length 1,020 ft. When it is realized that the former ship was equipped with engines barely equal to the power equipment of a modern trawler, our respect for the pioneers in sea transport is greatly increased. The horse-power of the *Queen Mary* is nearly 200,000 whilst that of the *Britannia* was 740. The author deals with the auxiliary plant which the Metropolitan-Vickers Co. supplied to the *Queen Mary*. These have chiefly to do with the winches and the ventilating system. There are six cargo winches, the same number of gangway winches and three baggage winches. These three types are all self-contained water-tight units. The ventilating system is naturally very extensive. There are no less than 40 miles of duct through which 118 million cubic feet of air are driven per hour.

Mediterranean Unity and Diversity

THE unity of the Mediterranean world in all geographical aspects, physical, climatic and vegetational, is a familiar conception to all geographers, and nowhere has the theme been more ably expounded than in a lecture by Dr. G. Sarton on "The Unity and Diversity of the Mediterranean World" (*Osiris*, 2, Part 9). While he dwells on this unity, enhanced by relative enclosure, he points out also the effective channels by which the area is linked with the outer world, especially with the civilizations of the East in ancient times, and the diversity within the larger unity owing to enclosed seas and restricted area of high fertility. These ideas he expounds as a background for a study of Mediterranean civilization. Among many links between geographical conditions and human development, Dr. Sarton takes the myth of St. George. Everywhere in the Near East, Al-Khidr, the young or ever-living one, is venerated by Muslims as well as by Jews and Christians. The festivals of Al-Khidr, Elijah and St. George occur on the same day, April 23, which, irrespective of religion, is one of the important holidays. St. George or Al-Khidr is not simply an ever-living one but a giver of life, for he is the most powerful rain-bringer, and in the Mediterranean rain has a vital significance. His name is connected with the struggle against darkness, winter and drought. He is the recrudescence of spring and he symbolizes the struggle against evil and ignorance. Dr. Sarton suggests that if ever the historian of science should need a patron saint, he could not find a better one than Al-Khidr or St. George, the ever-living symbol of Mediterranean unity and diversity, of our culture and ideals, and of the everlasting struggle between truth and superstition.

Forests of Trinidad and Tobago

THE forests of Trinidad are not one of the least of its beauties, and a recent informative statement on them ("Forests and Forestry in Trinidad and Tobago". Govt. Printer, Trinidad, 1935) was drawn up by Mr. R. L. Brooks, the conservator of forests, for the British Empire Forestry Conference held in South Africa last year. The statement covers the whole field of forestry administration tracing the past history, geographical position, geology, climate and distribution of the forests in the Islands; and the botanical types of the forest growth. There is a small amount of private planting undertaken, but forestry activities are chiefly confined to the Department of Forestry. Co-operation exists between the Agricultural Society of Trinidad and Tobago and the Department. This Society publishes a quarterly record of its work in its *Proceedings*, but the chief scientific journal of Trinidad is *Tropical Agriculture*, the monthly journal of the Imperial College of Tropical Agriculture, in which forestry articles occasionally appear. The problems connected with forestry in its professional aspects are discussed in some detail by the conservator, Mr. Brooks, whose statement may be confidently recommended to those visiting Trinidad wishing for information on the Islands not available in the ordinary popular guide books. It suffers, as is the case with others submitted to the Empire Forestry Conference, in having been drawn up on a common prescribed schedule. A "Progress Report on Exotics" and a statement on "Timber Consumption and Marketing" were also drawn up for Trinidad and Tobago for the Empire Conference.

The Lyre-bird in Victoria

CONCERN has been expressed at the possibility of the extinction of the lyre-bird in Victoria, but F. Lewis, chief inspector of fisheries and game, points to the improvement which has taken place in public opinion, the more rigorous protection by law, and the fact that a great deal of the land inhabited by lyre-birds is rough and inaccessible (*Victoria Naturalist*, **53**, 12; May 1936). He is of opinion that the future of the lyre-bird is assured, granted that public opinion in favour of protection continues to be educated in country districts as well as in the cities, and that a stop should be put to the clearing of lyre-bird gullies and the destruction wrought by bush-fires and the activities of egg-collectors. In another paper in the same journal (p. 3), R. T. Littlejohns states that no other Australian bird adheres so strongly to a definite area. In this case, the territory is two or three acres in extent, and for week after week, especially during the singing season, the place of any particular individual may be known exactly. It is seldom indeed that a bird is to be found outside its own area.

Allotments as an Amenity Asset

ALTHOUGH few will question the value of allotments, their frequent unsightliness is one of the chief reasons why there is so little public support for including them in town-planning schemes or otherwise making their tenure secure. Useful work has already been done by the National Allotments

Society and the Society of Friends, but expenditure on outlay is necessarily restricted when the land may (after three months notice) be sold to a speculative builder. Lady Allen of Hurtwood discusses this problem in a booklet entitled "How Allotments could be made an Amenity Asset to the Community". Constructive suggestions for the development of the allotment garden as an outdoor social centre are made, stress being laid on the necessity for well-considered planning of the land from the start, if possible in conjunction with other forms of social activity. An illustration is given of a suitable lay-out designed by the author herself, and sketches for a community centre building and hut units by William Tatton Brown are also included. The booklet (price 4*d.* post paid) may be obtained from The Housing Centre, 13 Suffolk Street, London, S.W.1.

Professional Workers in the Ukraine

FIGURES have recently been issued by the Soviet Union Year Book Press Service relating to the increase in the number of Soviet professional workers in the Ukraine. In 1914, the territory now constituting Soviet Ukraine had 44,083 teachers ; at the beginning of the school year 1936–37 the number had risen to 150,000. The number of medical men in 1913 was 5,192, in 1936 it was 19,266. The number of secondary medical staff in 1913 was 8,357 and in 1936 40,243. In 1934 there were 83,390 engineers and technical experts employed in the Ukraine ; in 1936 the number had increased to 116,600. The number of agronomists employed by the Commissariat of Agriculture in the Ukraine three years ago was 8,200 ; in January 1936 it was 12,346.

The Public Health Act, 1936

THE Ministry of Health has issued a circular to local authorities reminding them that the above Act, which passed into law in July last, comes into operation on October 1, 1937 (Circular No. 1576. H.M. Stationery Office). Attention is directed to some of the more important changes introduced in the new Act and to matters which call for early consideration. This Act consolidates in some 350 sections the provisions of more than six hundred sections contained in some sixty existing Acts.

Gift to the Royal Aeronautical Society

MR. C. R. FAIREY, past president of the Royal Aeronautical Society, and Mr. F. Handley Page, vice-president, have jointly agreed to give £750 a year for seven years to the Society. The object of this gift is to enable the Society to carry out as fully as possible its main object, "the general advancement of aeronautical science and engineering", and to enable it to be placed on a self-supporting basis. The intention is that the Society should become completely independent of donations from outside bodies, so that it may be free to express opinions upon aeronautical research and engineering when necessary, and can encourage the dissemination of papers, etc., on all matters pertaining to aeronautical research and engineering.

Announcements

THE Right Hon. the Viscount Falmouth has been appointed a member of the Advisory Council to the Committee of the Privy Council for Scientific and Industrial Research. Prof. A. C. G. Egerton has retired from the Council on completion of his term of office.

SIR JOHN PARSONS, the new president of the Royal Society of Medicine, has recently returned from the United States, where he was awarded the Lucien Howe Medal of the American Ophthalmological Society.

PROF. NOCHT, the founder and former director of the Institute of Marine and Tropical Medicine at Hamburg, has been awarded the Gold Medal of the University in recognition of his great services to the University in the domain of scientific work overseas.

ERRATUM. In NATURE of November 21, p. 875, paragraph entitled "Grassland of Great Britain", line 16, for "150 ft. contour" read "1500 ft. contour".

APPLICATIONS are invited for the following appointments, on or before the dates mentioned :

Two male pharmacists in the Royal Naval Hospitals—The Medical Director-General of the Navy, Admiralty, S.W.1 (November 28).

A mechanical and automobile engineer in the Yorkshire Traffic Area office at Leeds—The Establishment Secretary, Ministry of Transport, 6 Whitehall Gardens, S.W.1 (November 30).

A chief agricultural officer to the Salop County Council—The Clerk of the County Council, Shirehall, Shrewsbury (December 5).

An assistant physicist in the Radiotherapy Department, Royal Infirmary, Bradford—The Secretary-Superintendent (December 7).

Assistants (Grades II and III) in metallurgy in Admiralty Dockyard Establishments—The Secretary of the Admiralty (C.E. Branch), Whitehall, London, S.W.1 (quote *C.E.* 7180/36) (December 12).

A lecturer in mining surveying and economics in the Bulawayo Technical School—The Official Secretary, Office of the High Commissioner for Southern Rhodesia, Rhodesia House, 429 Strand, London, W.C.2 (December 12).

An assistant director, with a knowledge of textiles, of the Testing House and Laboratory of the Manchester Chamber of Commerce—The Director, Testing House, Royal Exchange, Manchester (December 15).

A taxidermist and an articulator in the National Museum, Melbourne—The Agent-General for Victoria, Victoria House, Melbourne Place, Strand, W.C.2 (January 4).

A professor of mechanical engineering in the Benares Hindu University—The Pro-Vice-Chancellor, Benares Hindu University, Benares, India (January 15).

A county agricultural organizer in Leicestershire —The Director of Education, Gray Friars, Leicester.

A lecturer in mathematics (woman) in the Avery Hill Training College, Eltham, S.E.9—The Principal.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 934.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Atrophy, Burial, Suppression or Total Loss in Evolution

AN examination of a series of sheep embryos has indicated that the ungulates are not removed from the general mammalian plan to the extent usually indicated by the specialization of their fore- and hind-limbs in the earliest Tertiary period. In 1890[1] Wincza described a transient rudiment of a bony clavicle in the embryo of a sheep at the site of the fibrous raphe of Leisering in the muscle sheet spreading from the head to the trunk and forelimb. The study of a group of fossil forms by Cuvier, Darwin, Owen, Cope, Matthew and others has brought to light a number of extinct suborders, of which the Typotheria, alone amongst the adult ungulates, possess definite bony clavicles.

The clavicle is visible by strong trans-illumination in the sheep embryo of 39–42 days and in a radiograph taken with a 'soft' tube; it is still more easily seen on staining the skeleton with alizarin or on histological section. In a transverse section of the neck of a sheep embryo of 36 days the clavicle appears (Fig. 1) as a condensation of mesenchyme cells. At 39 days the cells enlarge and become osteogenic in character; bone is laid down (Fig. 2) and appears as a system of trabeculæ in the intracellular matrix. Ten days later, the bony clavicle disappears leaving only a fibrous raphe in the occipito-humeralis muscle.

This transient waxing and waning of the bony clavicle in the sheep embryo suggested that the bony elements of the limb should be examined. The cannon bone of the adult sheep consists of the fused third and fourth metacarpals or metatarsals. The first, second and fifth bones are absent. In the fore-limb of a sheep embryo of 65 days, the fifth metacarpal is visible as a thin long bone of about 0·4 mm. in diameter in the radiograph, in the specimen stained with alizarin (Fig. 3) and in histological section. A week earlier the fifth metacarpal is entirely cartilaginous (Fig. 4). At 90 days there is no trace of this fifth metacarpal.

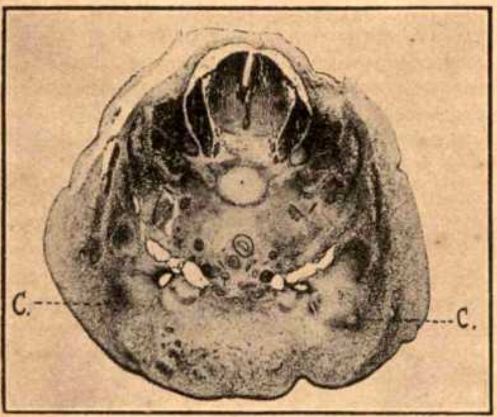

FIG. 1. Transverse section of the neck of a sheep embryo of 36 days. The condensation of mesenchyme cells to form a clavicle (*C*) is marked. (× 12·5.)

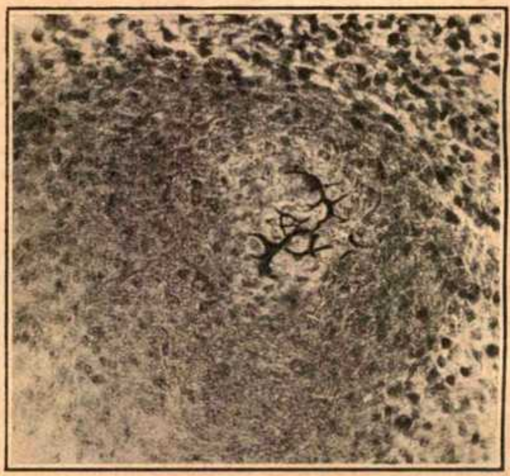

FIG. 2. Ossification centre with osteoblasts and bone trabeculæ in the clavicle of a sheep embryo of 39 days. (× 160.)

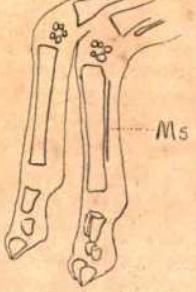

FIG. 3. Tracing of the fore-foot of a sheep embryo of 65 days indicating the cannon bone (fused metacarpals three and four) and the transient fifth metacarpal (*M*.5).

Transverse sections of the metatarsus of the sheep embryo of 36–42 days have been examined. Four metatarsals are present at an early stage. Two of these (the third and fourth) become centres of rapid growth, whereas the second and fifth grow slowly. The subsequent growth in diameter of the third and fourth becomes so great that they soon touch the second and fifth respectively, and eventually bury them, so that the shafts of the two latter are in process of being enclosed within the shafts of the actively growing bones (Fig. 5, *a* and *b*). The reduction of the metatarsals is thus not accomplished by suppression but by incorporation. At a later stage no trace of the buried elements is seen. Thus it is possible to see in a few days in the life of the sheep embryo a process of evolutionary reduction which has taken aeons of geological time—a story worked out in the study of ungulate fossil forms by Cuvier, Owen, Darwin, Cope and Matthew.

Edgeworth[2] has recently indicated that the important problem in morphology is to ascertain whether a given structure undergoes atrophy during life or whether it has ceased to exist. It is well known that a separate bony costal element near the transverse process of the seventh cervical vetebra is present in almost all human fœtuses. After birth this fuses with the transverse process. Occasionally it continues to grow and gives rise to the condition known as 'cervical rib'. The cervical rib sometimes gives rise to a palsy of the small muscles of the hand as a result of pressure on the brachial plexus. The patient is not to be regarded as a freak who has grown a new cervical rib, but as an unfortunate who has failed to keep the embryonic rib within normal bounds by fusion and suppression. Similarly, many of the abnormalities of the hands and feet in the quadrupeds are a failure to absorb and suppress various elements in the normal embryological sequence, rather than the acquirement of additional bony elements in the limbs.

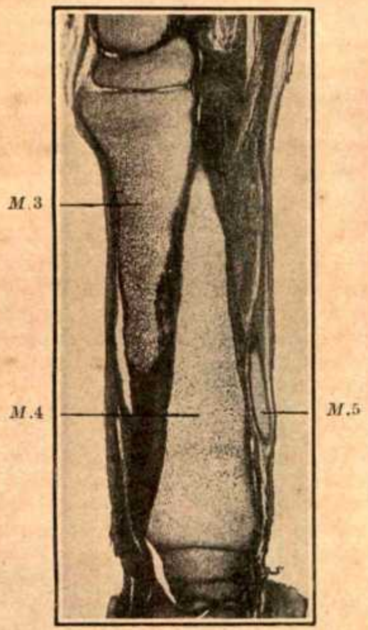

FIG. 4. Longitudinal section of the fore-foot of a sheep embryo of 56 days, showing metacarpals three and four and the transient small fifth metacarpal (*M*.5) in the cartilaginous state.

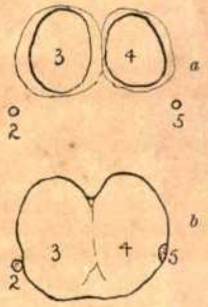

FIG. 5. Tracings of the transverse sections of the metatarsus in a sheep embryo of 39 days to indicate the gradual incorporation of the second and fifth metatarsals in the rapidly growing third and fourth metatarsals which fuse to form the cannon bone.

The process of burial and absorption of the bony elements of ungulates may be significant in the study of the distribution of tumours and cysts in this area, for the sites of embryological happenings may often be the sites of pathological changes. Finally, it is not without interest that the date of ossification in the clavicle of the sheep, the 39th day, is identical with that in the human embryo, as is the ossification in the transverse fifth metacarpal in the 8th–9th week of fœtal life. The divergence in the pattern of ossification in the sheep and human forms is negligible in the first 6–8 weeks and becomes of rapidly increasing significance, inasmuch as the sheep at birth has reached a measure of skeletal ossification which is not reached by man until seven years after birth.

Physiological Potency of Dilute Traces

THE attention of readers must have been arrested by the brief reports contributed to NATURE[1] at various times by Mr. Hugh Ramage, an eminent spectroscopic chemist, on the concentration of certain metals in special tissues of plants and animals, up to amounts spectroscopically measurable. The explanation would be that the ultra-infinitesimal amounts of these metallic substances that are present in the food that passes through the organism must be arrested in the organs concerned until the accumulation becomes sensible. An opening seems here to arise into the chemistry of minute traces, which is the aspect of that science that promises most for mathematical development.

But my present motive is a different one. In a recent report of the Medical Research Council astonishment is expressed at the potency, continued for as long as a month, of a minute injection of a substance refined from liver extract, in staving off pernicious anæmia—a result with which the writer has unfortunately some practical acquaintance. On the analogy of the metallic accumulations above, this substance may be arrested, but now more rapidly, in the lumbar bone marrow which is the seat of the production of the red blood corpuscles, so as to restore its function to a degree that may last a month before decay has again set in. At any rate this analogy, perhaps not novel, renders its efficacy in one respect less wonderful.

The relations of a virus and its counteracting serum may perhaps provide an illustration. For example, the virus of hydrophobia is distributed through the system by the circulation of its fluids, so that it soon becomes very dilute: where this flow passes through the nervous structures the virus is arrested chemically by some type of affinity, and gradually accumulates until its destructive action on the nervous framework acquires full play. This process may take a long time. The antidotal serum spreads also dilute throughout the system; but at *every* place in it the two dilute constituents virus and antidote come together by intimate diffusion, which is a rapid process, with destructive result by their mutual combination.

The principle underlying the production of a blocking or destructive serum as an *excretum* limiting or destroying the activity of the agent that emits it need not be involved here. The antidotal serum introduced quite late has thus time to overtake the virus. This is only an amateur analogy, effective just by reason of its limitation of range, as this indeed may be all that is open to us in such organic structural problems: there may be nothing essentially novel in its present explicit statement. Yet even Pasteur was an amateur.

The phenomena which used to be grouped under the name chemotaxy, and also the mode of transfer of hormones, might arise from cognate activities.

Gaseous Combustion

IT was shown by Mallard and Le Chatelier more than fifty years ago that, during the passage of flame through an inflammable gaseous mixture, two types of flame movement were clearly distinguishable, namely, the initial uniform slow movement and the very rapid movement known as detonation which is set up—if the mixture is strong enough—after the flame has travelled some distance.

Prof. W. A. Bone states that there is now much evidence for the view that, during the initial slow movement, combustion is far from being complete in the flame front, but that as the detonation stage is reached, combustion in the flame front becomes practically complete[1]. With this view I am in agreement, provided that incomplete combustion is not identified with incomplete combination but is to be accounted for by a stable form of latent energy formed in the flame front and left behind in the flame gases. The nature of the latent energy must for the present be left vague, but it seems probable that it will be found to be located in metastable molecules of some kind or other which result from the reactions in the flame front.

The reason why incomplete combination would appear to be ruled out is that it must remain constant in amount for a very long time after the flame front has passed if it is to explain flame temperature[2] and explosion and heat-loss[3] measurements, and this, of course, is most unlikely. Furthermore, had the photographic studies by H. B. Dixon, Bone and others of flame-travel in tubes been made with tubes of very large diameter, so that the cooling of the inflamed gases did not take place rapidly, it would have been found that the duration of the after-glow of the inflamed gases was so long as to be inconsistent with an explanation in terms of incomplete combination. Indeed, in some explosion experiments made in a very large vessel, the after-glow continued for at least 14 seconds[4], and it is a fair inference that had the explosion vessel been still larger so that the cooling would have taken place much more slowly, the luminosity would have lasted for a longer time than this.

It has been shown that the latent energy left behind in the flame gases decreases markedly with the pressure at which the gases are burnt[5] and, since the pressure in the flame front during detonation is very high, it is to be expected that the latent energy in the detonation phase would be much less than in the initial slow movement phase. Assuming also, as would appear to be legitimate, that the latent energy decreases with distance of travel of the flame front, a completely satisfactory explanation is obtained as to why there is a smaller proportion of latent energy in large vessel explosions than in flames[3].

Our experiments, so far as they have gone, have shown latent energies varying between 1 per cent and 10 per cent of the heat of combustion in explosions[3], and between 6 per cent and 28 per cent of the heat of combustion in flames[5]. Doubtless further experiments will show that these limits may be extended in either direction. There seems little doubt that the amount of the heat of combustion remaining in flame gases as latent energy depends not only on the pressure at which combustion takes place in the flame front, but also upon the nature of the combustible gases and the diluent gases[3,5].

Ordinary gas calorimetry shows that the latent energy, which our experiments show to be long-lived, entirely disappears during the passage of the flame gases through the calorimeter. The after-glow shows that it tends to disappear when the temperature is sufficiently high to produce collisions of the kind which will enable the metastable molecules to attain the ground state, but this is clearly a very slow process, and it seems probable that the bulk of it disappears when the flame gases come into contact with surface. Preliminary experiments designed to test this have been apparently successful, but they have not yet reached a stage at which publication is desirable. Meanwhile, attention may be directed to Dr. F. W. Lanchester's calorimeter experiment, in which there was no surface and in which he could only account for at most 85 per cent of the heat of combustion[6]. It is of interest, too, in this connexion to point out that flame gases, after having been cooled to a temperature so low as 200° C. in the cylinder of a gas engine, have been made luminous again by adiabatic compression[4]. The adiabatic compression ignition experiment of Tizard and Pye in which explosion took place on the second compression[7] would also appear to be relevant.

Red and Sunlit Auroras and the State of the Upper Atmosphere

ON October 16 this year, a strong auroral display was observed at Oslo. It commenced as an arc fairly low on the northern sky, but at intervals it took the form of a drapery-shaped band with pronounced ray structure, and sometimes—for example, between 22^h and 23^h in the evening—rays of quite unusual length (several hundred kilometres) were observed.

These observations show that extremely long rays may appear also on the night side of the earth, and that they are not restricted to regions exposed directly to sunlight.

Our direct measurements from auroral band spectra gave a night temperature of −30° to −47° C. in the auroral region. Thus the slow rate of decrease of density from 100 km. and upwards as shown by the long auroral rays cannot be accounted for by a high temperature, but as I have stated in previous papers, it must be due to an electrical state of the atmosphere, resulting from the action of ultra-violet light or corpuscular rays entering the atmosphere during auroral displays and magnetic disturbances.

On account of these influences, a large proportion of the matter in the auroral region consists of electrons and free atoms, and *this dissociated state will have an effect on the distribution of matter similar to that of a large reduction of average molecular weight or increase of temperature.*

In the morning (of October 17) a spectrogram of sunlit auroras was obtained on panchromatic plates[1]. In this case, the red line (6300) appeared with a photographic density even considerably greater than that of the green line. If the line 6300, which is enhanced from sunlit auroras and for red auroras of type A, is due to the transition $({}^1D_2 - {}^3P_2)$ of oxygen, then the two other weaker components ought also to be enhanced. In previous spectrograms of red and sunlit auroras, only the strongest component has been observed. On the spectrogram obtained on the morning of October 17 the second weaker line $({}^1D_2 - {}^3P_1)$ was also observed. *This result shows that it is the oxygen triplet* $({}^1D - {}^3P_{012})$ *which is enhanced in the sunlit and red auroras (of type* A*).*

Red auroras of type A were observed for long intervals during the night; *but they were restricted to certain fairly limited regions of the sky* (mostly the north-east), while at the same time auroral bands, streamers and long rays appeared with the ordinary greenish-white colour.

As a rule, the red auroras of type A are red throughout the whole length of the streamer from top to bottom. In this case, however, we found that the red colour was restricted to the upper region, while the lower part had the ordinary greenish colour. This was verified by spectroscopic observations. In the upper red part of fairly small intensity, the red line 6300 was clearly visible, while the lower more intense part, where the green line appeared very much stronger, the red line could not be seen.

In this way we have proved that, at any rate under certain conditions, *the intensity of the red line* 6300 *relative to that of the green one* (5577) *increases upwards.*

If the life-time of the metastable $({}^1D_2)$-state is of the same order of magnitude as the average time between molecular collisions in the auroral region, the intensity of the red triplet O I $({}^1D_2 - {}^3P_{012})$ must increase with diminution of density and increasing height.

In this way we might account for the observed altitude effect. The fact that most auroras—even very long rays—do not appear red at the top, shows that the enhancement of the O I $({}^1D_2 - {}^3P_{012})$ triplet of the sunlit and red auroras cannot be entirely due to a change of density, but, as I have previously mentioned, there must be some excitation process which brings the oxygen atom to the $({}^1D_2)$-state and not the ${}^1S_0$ state, and this process must be attached to some *variable* component of the atmosphere.

Some years ago I suggested that the enhancement of the red line was due to the action of activated nitrogen on ozone molecules, resulting in the expulsion of an oxygen atom in the $({}^1D_2)$-state. This explanation is supported by the fact that the red colour is, for long intervals of time, restricted to certain regions of the sky. This gives indications of a very variable ozone concentration—perhaps due to violent or eruptive motions or local precipitations of corpuscular rays—occurring in the upper regions.

Clocks showing Mean and Sidereal Time Simultaneously

IN the Paris Observatory a number of clocks provided with two dials showing sidereal and mean time were installed last year as part of the permanent equipment of the Observatory. This suggested to me an investigation of the many ingenious attempts to achieve it, and to seek a simpler and better method.

The problem involves the precise expression of the ratio between the sidereal and mean time in the form of a train of gear wheels. Since one mean solar day is $24^h\ 03^m\ 56{\cdot}555\ 36^s$ in sidereal time, the ratio of sidereal to mean is 1·002 737 909 3. . . . This ratio must be expressed by a fraction; for our purpose the numerator and denominator of this fraction must both be factorizable into factors not exceeding a few hundreds, as the number of teeth on any wheel cannot reasonably exceed this. Moreover, the number of factors (or suitable combinations of them) in the numerator and denominator must be the same, as wheels must work in pairs.

The first to accomplish it was George Margetts, a member of the Clockmakers' Company *circa* 1800. It is in the form of a large watch and is to be seen in the Company's collection in the Guildhall. It has separate dials for hours, minutes and seconds, each having a smaller dial mounted concentrically with the larger ones. These inner dials were gradually revolved backwards by gearing, so that the same three hands indicated simultaneously mean time on the outer dial and sidereal time on the inner dial. His train includes a wheel of 487 teeth so fine that they are invisible to the naked eye. The ratio is $\frac{1465}{1461} = \frac{5 \times 293}{3 \times 487} = 1{\cdot}002\ 737\ 85$, which is correct to the sixth decimal. The sidereal component would lose at the rate of $1{\cdot}8^s$ in a year.

In the Science Museum there is a clock designed by Joseph Vines a hundred years ago (1836), with two dials coupled by the ratio $\frac{43 \times 247}{32 \times 331}$. This is 1·002 737 915 4, which is correct to the seventh decimal. It will take 5·2 years for the sidereal dial to be in error relatively to the solar dial by one second.

Paris adopted a train by Ungerer, of Strasbourg, $\frac{119 \times 317}{114 \times 330}$, which is 1·002 737 905 4, and correct to the eighth decimal; it will be 8·2 years before it is a second wrong.

Sir George Airy contributed to the *Monthly Notices of the Royal Astronomical Society* in 1850 a train by Dr. Henderson, $\frac{50 \times 182 \times 196}{30 \times 211 \times 281}$, a ratio of 1·002 737 908 5. This is very close, being correct to the ninth decimal, and requiring forty years to accumulate an error of 1 sec.

At this stage of the investigation, I was fortunate in interesting Dr. L. J. Comrie who, as a result of "a pleasant week-end's arithmetical recreation", summed up the whole matter and contributed a solution which we may accept as final. He gives the true ratio as 1·002 737 909 265, plus the centennial term, and a wheel train of $\frac{45 \times 71 \times 257}{29 \times 151 \times 187}$ which is the value of the precise ratio required in the year 1955, namely, 1·002 737 909 297. The error would amount to one second in about 100,000 years.

---

[1] Cf. L. Vegard and E. Tönsberg, NATURE, **137**, 778 (1936).

The Paris installation mentioned above suffers from a shortcoming common to every combined mean solar and sidereal clock yet made. They have invariably derived their time from a pendulum driven by an escapement in steps; hence it is necessary to decide whether to rate it for mean solar time and gear it up to sidereal or vice versa. Whichever is chosen, the progression of the wheelwork, and therefore the hand of *both* dials, will advance in seconds of the same length. If it is dead-beat on the divisions on the mean time dial, the pointer will creep forward progressively on the sidereal dial, gaining a second in about six minutes; conversely, if the clock is rated to be dead-beat on the sidereal dial it will creep backwards on the mean dial. Thus a dead-beat reading on both dials is never attained.

By means of a simple device, however, the problem of giving dead-beat seconds hands on both dials has been solved. A synchronous motor of 50 cycles per second is applied to the mean time end of the train and is driven by the alternating current on the Grid. Since the *average* frequency of 50 cycles is rigidly maintained, there is no cumulative error. The automatic time control of the speed of our turbo-alternators is an ambition that has already been realized in individual stations. The conditions laid down by the Central Electricity Board for the technical management of the Grid are such that the disturbances inevitably caused by load sharing will be progressively diminished. Astronomers can help the campaign to improve the timing of the Grid by making their requirements known.

In the meantime, either end of the wheel train of these clocks can be synchronized from the Royal Observatory's standard slave clock. For those who fear breakdowns, in spite of the steady progress of our generating stations towards the high standard of continuity of service that they have set themselves, a simple little instrument is available to take up the duty automatically if the alternating current is cut off.

Synchronous motor clocks are destined to prove extraordinarily useful for purposes that were not visualized at the time of their introduction in the United States in 1919, although forty years ago I forecast that they would be the electric clocks of the future. This combination of mean time and sidereal time clocks is just another instance of the utility of the synchronous motor method.

Stability of Rotating Threads

STUDIES of rotating threads have disclosed some curious features with regard to the spiral sinusoidal forms which they assume. Two simple cases were first examined experimentally in order to explain anomalies in the third. The three cases are (1) a long freely hanging thread, attached to a horizontal rotating arm, supporting a spherical weight (M), (2) a thread similarly rotated about a horizontal axis, the thread passing over a light pulley at the loaded end, and (3) a thread withdrawn vertically at high speeds from its rest position closely coiled on a vertical cylindrical surface (that is, a full parallel-wound yarn bobbin) through an eyelet situated at an axial distance (L) above the surface.

Case (1) is illustrated in Fig. 1, *a* and *b*, and Case (3) in Fig. 1*c*. Fig. 1*b* shows two spiral stroboscopic images and the general form of the thread. The images were obtained by using a beam of light interrupted by an inverted metal bowl (containing two diametrically opposite slots) attached to the rotating head.

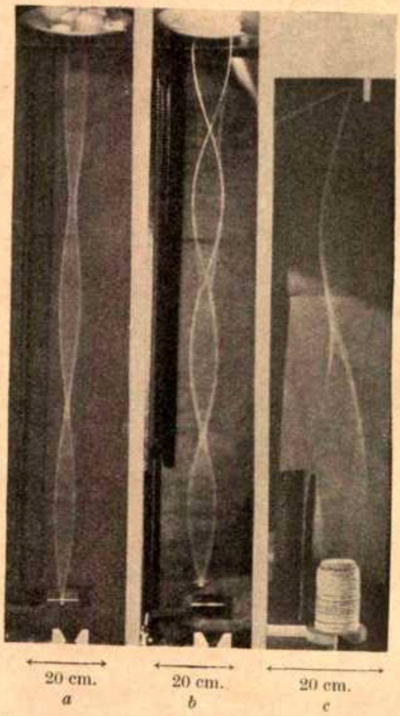

FIG. 1.

In the first two cases, measurements of the average loop lengths (l) agree closely with the well-known formula for plane vibrations in a thread

$$l = \frac{1}{2n}\sqrt{\frac{Mg}{m}}$$

even for an arm radius as high as 5 cm., n being the revolutions per second of the rotating arm and m the mass per centimetre of the thread.

In the third case a tension recorder was placed in the path of the thread above the eyelet, and records were obtained showing the tension varying from a maximum to a minimum as the thread uncoils from the base to the top of the bobbin. With uniform close coiling on the bobbin, L being fixed, the tension traces rise and fall in a series of sharp steps and are symmetrical about the peak value. These 'jumps' and 'drops' to new tension levels (T) occur when instability of the thread causes it to change to a new form containing a greater or smaller number of loops. The tension peak values vary discontinuously with the value of L, other things being constant. On plotting the tension levels, T, against L, the points tend to lie on a series of approximately co-axial parabolas represented by

$$L = \frac{s}{2n}\sqrt{\frac{T}{m}}$$

where s is somewhat less than 1, 2, 3, etc. The smaller the bobbin radius, however, other things being equal, the more closely s approaches 1, 2, 3 . . . etc.

If the thread in Case 1 be progressively shortened, alternating ranges of stable and unstable length are traversed. Further, if cathetometric measurements are made of the rise h of the weight M due to rotation, it is found that (*a*) h rises regularly to approximately the same maximum for lengths of thread accommodating a complete number of stable loops; (*b*) h falls to a minimum for lengths accommodating approximately $(p+\frac{1}{2})$ stable loops, p being integral; (*c*) in the range of thread length which accommodates $(p+\frac{1}{2})$ to $(p+1)$ loops the loop form is stable: for lengths accommodating p to $(p+\frac{1}{2})$ instability occurs, but transition points from stable to unstable lengths are not experimentally very sharp; (*d*) the loop length is not measurably dependent on the total thread length.

Since h is indirectly a measure of loop amplitude (the arm radius, etc., being constant), the amplitude must depend on the total length of the thread, the number of complete loops and the fraction of a loop which it accommodates.

Examination with stroboscopic illumination showed that in air and under all conditions imposed, the thread spirals through an angle π for each complete loop.

It is hoped to publish further details and a mathematical treatment of the first two cases elsewhere.

State of Ascorbic Acid in Plant Tissues

THE cause of the apparent gain in the ascorbic acid content of vegetables brought about by cooking has given rise to much correspondence in these columns. An attempt has been made in this laboratory to explain this phenomenon along the lines of either the 'combined ascorbic acid' or 'oxidase' theories, experiments being conducted along the following lines:

25 ml. aqueous extracts of cauliflower (C) or potato (P)

Expt. No.	Treatment	Ascorbic acid found before H_2S reduction (mgm.)	Ascorbic acid found after H_2S reduction (mgm.)
1	C (*a*) 6·25 ml. water added	0·20	2·42
	(*b*) 6·25 ml. 10 per cent metaphosphoric acid added. Precipitate filtered off		1·60
	(*c*) As in 1(*b*) using 13·3 per cent trichloracetic acid		1·04
2	P (*a*) 6·25 ml water added	<0·06	2·36
	(*b*) As in 1(*b*)		2·26
	(*c*) As in 1(*c*)		
3	P (*a*) 6·25 ml. water added	<0·06	2·31; 2·20
	(*b*) As in 1(*b*)		1·76; 1·76
4	C (*a*) 6·25 ml. water added	<0·06	2·48
	(*b*) Boiled 20 min. (reflux). Cooled. 6·25 ml 10 per cent $(HPO_3)_x$ added		0·28
5	P (*a*) 6·25 ml. water added	<0·06	2·36
	(*b*) As in 4(*b*)		0·28
6	C (*a*) 6·25 ml. water added	<0·06	1·24
	(*b*) Boiled 20 min. (reflux)		0·11
	(*c*) As in 1(*b*)		0·71
	(*d*) As in 6(*c*). Boiled 20 min.		0·30

The first three experiments confirm the presence of combined ascorbic acid in potato and cauliflower as demonstrated by McHenry and Graham[1]. 2 per cent metaphosphoric acid gives the true value of free ascorbic acid in the extracts, bearing out the findings of Fujita and Iwataka[2] that this acid is preferable to trichloracetic acid.

Experiments 4 and 5 show the tremendous losses in 'total ascorbic acid' experienced on boiling. Van Eekelen[3] has obtained similar results. This indicates that the oxidases are still active during the heating, and must be only slowly destroyed. If the oxidases were completely inactivated, then the length of time of heating should not affect the ascorbic acid content at all.

Experiment 6 demonstrates that the oxidase activity of acidified extracts is somewhat decreased, indicating the important part played by the acid in the destruction of the enzymes. Also aqueous extracts with the vitamin present in the reversibly oxidized form are more liable to loss in activity during boiling. The statement of McHenry and Graham[4] that reduced aqueous extracts of cauliflower give the same titration values as an equivalent amount of the vegetable after heating and subsequent reduction can only be explained by the fact that cold aqueous extraction is far from complete.

The failure of Mack[5] to observe any increase in the ascorbic acid content of cabbage on heating while repeating the experiments of Guha and Pal[6] is probably due to the very small content of the combined acid in cabbage. In fact this vegetable always shows a decrease of between 40 and 50 per cent in ascorbic acid on boiling.

In view of the above, it is evident that the combined ascorbic acid hypothesis for the apparent increase must be accepted, but at the same time it must be taken into account that oxidases are active during the boiling process which brings about the hydrolysis of this compound. Indeed, this increase in titration is not even as high as it would be, if the oxidases were rapidly and completely destroyed on heating.

Luminosity of Meteoric Trains

IT is well known that the portion constituting *nearly, but not quite*, the end part of a meteoric train is generally brighter and more persistently visible than the rest of it. Charles P. Olivier also refers to it in his book on meteors. The phenomenon may be explained as due to:

(1) The peculiar effect of density, composition and condition of the atmosphere between altitudes which mark the limiting points of persistent visibility of meteoric trains.

(2) The effect of velocity: only certain velocities that obtain along particular portions of a meteor track giving rise to persistent visibility.

As the velocity would obviously be smaller near the end part of meteoric trains, and it is more appropriate to associate better visibility with greater velocity as giving rise to more vigorous ionization of the surrounding air, it appears that the phenomenon is due only to the effect of atmospheric condition and composition.

It would be worth while, therefore, to collect data concerning the height and velocity of meteors along their tracks of *maximum* visibility, as distinct from their entire visible courses.

Meteors seen with very long streaks are doubtless those that move more or less horizontally, the major part of their journey being accomplished in the region of right density and composition.

It is common knowledge that only the brighter meteors have more or less persistent trains. This may be due to the 'gas-mantle' surrounding them, which gives them a higher luminosity and the air left in their tracks greater facility of ionization.

Meteors of low luminosity that appear as reddish (or reddish-white) specks, moving generally with small apparent velocity, rarely, if ever, develop persistent trains. Their tracks probably lie above the region of appropriate density and composition.

Curve Fitting

In *Biometrika*, 28, 34–59, the late Prof. Karl Pearson published a severe criticism of some work on curve fitting by the Indian statistician, R. S. Koshal. Since the criticism, if taken at its face value, is likely to injure the reputation and prospects of Mr. Koshal, I take this opportunity to point out that in the table (p. 44) in which Pearson contrasts his results with those of Koshal, much to the latter's disadvantage, Pearson's theoretical frequencies, said to be derived from his equation (v), are seriously in error. In consequence, his equation is made to appear to be a closer fit than that obtained by Koshal, although in reality it does not fit the data so well.

In this letter I cannot deal with the numerous points of Pearson's criticism. It is only fair, however, to recognize that it was evidently written under a misapprehension of the numerical values he was discussing.

Points from Foregoing Letters

PROF. H. A. HARRIS puts forward the view that the even-toed ungulates are not so highly specialized as would appear to be the case in view of the reduction of the digits to two and the absence of a clavicle. In the sheep embryo, a clavicle appears and various additional digits in the fore and hind foot. These are rapidly lost, either by absorption as in the case of the clavicle, or by incorporation in the neighbouring bony elements. The second and fifth metatarsals are buried in the substance of the rapidly growing third and fourth, which fuse to form the cannon bone.

Sir Joseph Larmor suggests that the potency of a minute amount of active principle from liver extract in staving off pernicious anæmia, may be accounted for on the supposition that the active principle is arrested in the affected lumbar bone marrow which, under normal conditions, is the seat of production of red blood corpuscles, and that it restores to it for a while its function.

Prof. W. T. David agrees with Prof. W. A. Bone that during the passage of a flame through an inflammable gaseous mixture the initial slow movement is accompanied by 'incomplete combustion'. He stipulates, however, that this incomplete combustion does not imply incomplete combination, but indicates that a certain amount of 'latent energy' formed in the flame front is left behind in the flame gases. This assumption he considers to be necessary in order to account for the duration of the afterglow of the inflamed gases, seen in wide tubes.

Recent observations of the spectra of northern lights (both 'red' and 'sunlit' auroras) indicate, according to Prof. L. Vegard, that the night temperature in the auroral region is − 30° to − 47° C. Therefore, he concludes, any inferred decrease in the density of the atmosphere from 100 km. upward cannot be accounted for by an increase in temperature; it may, however, be due to the presence of electrons and of free atoms, which would be equivalent to a decrease in the average molecular weight. Prof. Vegard finds, further, that under certain conditions the intensity of the red line (6300 A.) relative to the green line (5577 A.), increases upwards, and recalls his previous suggestion that the enhancement of the red line is due to the action of 'activated nitrogen' upon ozone molecules.

F. Hope-Jones describes a new clock showing simultaneously mean and sidereal time. With the help of a more accurate value for the ratio between the solar and the secular day, calculated by Dr. L. J. Comrie, and with a corresponding train of gears in the ratio $\frac{45 \times 71 \times 257}{29 \times 151 \times 187}$, the clock error has been reduced to one second in about 100,000 years and, by means of a simple device, the problem of giving dead-beat seconds hands on both dials has been solved.

Features concerning the stability of the spiral sinusoidal forms assumed by threads under rotation are described by H. W. Hall. Conditions of rotation for three cases have been examined; in the first two, fixed lengths loaded by weights were used, and, in the third, the thread was withdrawn vertically at high speeds from a stationary bobbin. Examination with stroboscopic illumination showed that in air and under all conditions imposed, the thread spirals through an angle π for each complete loop.

New determinations of the ascorbic acid (vitamin C) in cauliflower and potato, carried out by Dr. L. F. Levy, employing several methods of extraction, lend support to the hypothesis that the ascorbic acid exists partly in a combined state and is freed during boiling. On the other hand, oxidases which are active during the boiling process reduce the amount of ascorbic acid.

Research Items

Indian Temple Architecture

A VAST amount of fresh information necessitates a revision and simplification of Fergusson's treatment of styles in Indian architecture, towards which an interpretation of the facts and suggestions as to terminology are offered as a basis by Dr. F. H. Gravely, of the Madras Government Museum ("An Outline of Indian Temple Architecture." Bull. Madras Government Museum. N.S. General Section, 3, pt. 2). The separation of Buddhist, Jain and Hindu is unsound; Buddhism and Jainism sprang from Hinduism, and there is every reason for believing that their temples have a similar history. No essential architectural difference seems to exist. Pending the working out of the evolution of the decorative detail, form is the only available criterion of a system of classification. The *vimāna*, or shrine, has long been found the most helpful in distinguishing styles. In the northern form, the so-called 'Indo-Aryan', the vertical lines predominate over the horizontal, and the 'crown' resembles the *amalaka* (myrobalan) fruit. In the south, of various forms the most characteristic and widely distributed has a *vimāna* which consists of a series of successively smaller and smaller tiers of miniature pavilions, in which horizontal lines predominate over vertical, capped by a cupola-like 'crown'. Two styles are distinguishable in the southern temple, that of the Kanarese country, Early Chalukyan, and that of the Tamil country, which differs from the Kanarese in details of both decoration and form. In the west are two styles, that of the ancient Kadamba kingdom, in which the *vimāna* is square in plan with a pyramidal tower composed of a series of horizontal stages, and the Malabar, in which the walls resemble a wooden railing with a simple or multiple pitched roof suggesting similarities to those of Nepal and China. Multiple roofs are also found in the temples of Kashmir. Lastly, in Bengal, is a form of temple with a tendency to the multiple roof, which is evidently a copy from the leaf huts common in the area.

Effect of Noise

RECENT experiments by Dr. Foster Kennedy on trephined patients at the Bellevue Hospital, New York, have demonstrated that the noise resulting from the explosion of a paper bag raised the brain pressure to four times normal for seven seconds, and that thirty seconds elapsed before the pressure returned completely to normal. According to Dr. Kennedy (*N.Y. State J. Med.*, Oct. 5), the undoubted effect of constant noise is disturbance of the circulatory system and an increase in the degenerative processes in the heart and arteries.

Metabolism at High Altitudes

ACCORDING to the Soviet Union Year Book Press Service, a Soviet expedition sent out under the joint auspices of the Academy of Sciences of the U.S.S.R. and the All-Union Institute of Experimental Medicine to Elbrus, the highest mountain in the Caucasus and in Europe, has recently been making a study of metabolism at high altitudes. Analysis of the blood of donors revealed that the blood becomes thicker, the potassium content increases and the quantity of nitrogen falls. Studies were made of the relative change in the organs of persons who ascend to high altitudes directly and those who break the ascent by remaining at different altitudes for a period of time. The expedition also studied changes in the function of the organs of smell, circulation and respiration with the view of ascertaining the cause and course of mountain sickness. It is reported that the skin became hypersensitive to the sun's rays at high altitudes.

Pacific Dinoflagellates

DR. ANTON BÖHM has described the dinoflagellates, excluding *Ceratia*, from a collection of plankton made in the western Pacific by Dr. Victor Pietschmann in 1927–28 (Dinoflagellates of the Coastal Waters of the Western Pacific. Bernice P. Bishop Museum, Bulletin 137, January 1936). The material was collected with the ship's pump from depths of 1–6 metres during one or more hour's run and was filtered through nets. The author has already published a paper on the *Ceratia* (1931), from the collection in this same publication. This is the most comprehensive account of the group in these regions so far published, 111 species in all being described, 46 being new records for the district, 5 of which are new species. The distribution of these dinoflagellates in the east Asiatic waters shows the same arrangement that was found for the *Ceratia* population. The coastal waters from Singapore to Shanghai (in summer at the time of the south-west monsoon stream) show two strongly marked distribution areas which are connected by a transition zone. Area I, Singapore to Hong Kong, besides eurythermal and euryhaline forms, harbours the typical population which is neither purely oceanic nor purely neritic; Area II, the transition zone, shows warm water forms, and Area III, approximately the population of the East China Sea, the Yellow Sea and its boundary (Korea Strait), chiefly warm water forms. Certain widely distributed species, such as *Ceratium furca*, *Peridinium conicum*, *P. depressum* and others were observed in all the samples. The diagrammatic drawings of the variation, and measurements of the different species are interesting; some of the species vary enormously.

Coral-infesting Crabs

THE *Hong Kong Naturalist* (Supplement) for June 1936 (No. 5) contains Part 5 of a description with illustrations of the Hong Kong seaweeds, Sargassaceæ, by W. A. Setchell. Besides this very useful memoir, there is a paper by Dr. Chia-Jui Shen entitled "Notes on the Family Hapalocarcinidæ (Coral-Infesting Crabs) with Descriptions of Two New Species". These crabs usually inhabit the cavities or pits in living coral and "owing to their peculiar habitat their size is small and the anterior portion usually depressed and narrower than the posterior, so that the former can come out of the pit and the latter remain within". The author shows that there are only two valid genera in the *Hapalocarcinidæ* Stimpson, namely, *Hapalocarcinus* and *Cryptochirus*. The two new species described are *Cryptochirus hongkongensis* from Hong Kong and *C. granulatus* from Christmas Island [specimens from the British Museum (Natural History)]. Good figures are given of both species.

Northern Spy Apple Stock

A recognized means of combating the attacks of woolly aphis (*Eriosoma lanigerum*) is to use an immune root system and main stem on which desired varieties can be budded or grafted. The 'Northern Spy' stock has been widely used in this way, particularly in Australia, New Zealand and South Africa. Unfortunately, it cannot be regarded as a desirable rootstock from other points of view, and this view is confirmed by the work of Miss J. Hearman (*J. Pom. and Hort. Sci.*, 14, 3, 246; 1936). The characteristics of the stock were compared with those of several well-known Malling types by detailed examination of a number of root systems at the East Malling Research Station. Besides being difficult to propagate vegetatively, it appears that Northern Spy recovers very badly after transplanting. It is generally very shallow rooted, rarely sending down deeper roots from the periphery of the root system. On the whole, the growth habit can be described as weak and uneven, and compares unfavourably with such stocks as Malling Types I, II and IV.

Rejuvenating Old Rubber Trees

Although for some time past inorganic fertilizers have been successfully used for young *Hevea* trees, of late they have scarcely been used at all for old or deteriorated stands, partly owing to the economic depression in the rubber world, and partly because many planters were not convinced that it 'paid to fertilize'. During these last five or six lean years, however, Dr. W. B. Haines, of Dunlop Plantations, Ltd., and E. Guest have been conducting a series of large-scale experiments on the manuring of *Hevea* in Malaya, and have arrived at some important conclusions (*Empire J. Exp. Agric.*, Oct. 1936). These authors give 'chapter and verse' for their conclusion that the primary need of old or deteriorated rubber trees is nitrogen; young trees, however, mostly need 'minerals' as well. Response to manuring with nitrogen (4 lb. of sulphate of ammonia per tree) usually occurs in two stages. In the first, which is associated with improved foliage, the yield of latex increases by about 10 per cent; in the second, associated with improved bark renewal, the increase in yield averages about 35 per cent but does not begin until the second or third year after the initial application. As a rule, it does not pay to apply nitrogen unless the latex-yield has fallen below 400 lb. per acre; and it is suggested that the best criterion of the need of nitrogen is given by the growth-rate of the tree: when the annual girth-increment has fallen to, or below, ½ inch per annum, quick response to nitrogen may be confidently expected. The authors also review past experimental work, and discuss problems related to manuring, such as the use of cover crops and *Oidium* leaf-disease.

Recent Earthquakes in California

The latest quarterly number (for July 1936) of the *Bulletin of the Seismological Society of America* contains several papers on recent earthquakes in California. Messrs. P. Byerly and J. T. Wilson (pp. 207–213) continue their valuable list of Northern California earthquakes from April 1, 1934, until December 31, 1935, the number of earthquakes recorded being 170, and the number of centres in action 106. Only one of these earthquakes, that of Parkfield on June 7, 1934, was of destructive intensity. From the map and tables, it follows that, though there was an increase of activity in the Pacific region off the coast of Humboldt County, the coastal region between that county and San Francisco Bay was comparatively free from epicentres. The region lying to the east of Monterey Bay was remarkably active, and activity on the San Andreas fault crept northward to San Francisco. Mr. J. T. Wilson (pp. 189–194) also considers the distribution of the fore-shocks and after-shocks of the Parkfield earthquake. The epicentres of the principal earthquake and of all the minor shocks lay on the San Andreas fault, those of the three fore-shocks on the north-west side of the main epicentre and within 3 km. of it, while those of the eight after-shocks all lay on the other side at distances between 3 km. and 17 km. Thus, the total length of fault in action was about 20 km.

Tropical Storms

The mechanism of tropical revolving storms is not yet understood, for although theories about them abound, these do little more than show that certain factors not inimical to their development are present in the tropics, and there is still no way of foretelling where and when the storms must appear. Meanwhile, the volume of statistics relating to their incidence and life-history grows apace. The latest contribution to the statistics of the tropical storm is in the form of a memoir by V. Doraiswamy Iyer, entitled "Typhoons and Indian Weather" (*Mem. Indian Meteorol. Dept.*, 26, Part 6; 1936). Typhoons of 1884–1930 which came from the China Sea or the Pacific Ocean and had moved westwards to strike the coast of Indo-China or South China were studied, and it was found that 135 out of 370 re-developed into storms or depressions over India after having died out or become indistinguishable on entering the mainland lying in their path. This is contrary to the generalization of Sir John Eliot made many years ago in the infancy of synoptic meteorology, to the effect that "All cyclonic storms in the Bay of Bengal originate or are produced in the Bay itself"—a generalization that Eliot began to modify at the end of last century. The effect of these reconstituted storms on Indian weather is discussed, although not in great detail. The author follows the custom of to-day, according to which few students of storms of any kind fail to make a great effort to connect the storm with some kind of 'front'—in this case what is described as "the climatic front between the humid monsoon current and the comparatively drier winds from the north". The success of this effort can in this instance only be gauged by those who make a special study of synoptic meteorology, and are familiar with Indian weather.

Order – Disorder Transition in Alloys

C. Sykes and F. W. Jones (*Proc. Roy. Soc.*, A, 157, 213; 1936) have studied experimentally the order – disorder transitions in the alloy Cu_3Au. They examined the variation of specific heat with temperature, and also devised a method for finding directly the variation of energy content with temperature. This was valuable, since the alloy could first be brought to any condition, not necessarily that of equilibrium, and the energy change measured on heating to a standard temperature at which equilibrium was always attained. The specific heat method is only applicable to conditions in which the substance is always in equilibrium. The X-ray examination of heat-treated specimens was also used. The theories of Bragg and Williams and of Bethe and Peierls differ mainly in that the latter takes account of a 'local order' persisting above the transition point and due to nearly neighbouring atoms not being strictly random, although the superlattice structure has disappeared. Neither theory gives quite correctly the energy changes just below the critical temperature, but the Bethe-Peierls view explains correctly the existence of an abnormal specific heat above the critical temperature and fits well with evidence that nuclei of local order exist in the metastable structure obtained by quenching.

Molecular Weight of a Virus Protein

THE isolation by W. M. Stanley in 1935 of a crystalline protein showing the properties of the tobacco-mosaic virus was the first example of a chemically well-defined virus, previous preparations having been defined by means of biological tests only. Preliminary measurements gave molecular weights of the order of millions. I. B. Eriksson-Quensel and The Svedberg (*J. Amer. Chem. Soc.*, 58, 1863; 1936) have now examined the protein by sedimentation (ultra-centrifuge) and electrophoresis methods. The results show considerable inhomogeneity of molecular weight. At $pH = 6 \cdot 8$, about 65 per cent of the material has a molecular weight between 15 and 20 millions, provided the dissymmetry constant is the same as for other high molecular proteins. It is not improbable that the virus protein might be homogeneous with regard to molecular weight in its native state. Electrophoretic determinations showed the virus protein to be chemically well defined and practically homogeneous.

Electrolytic Oxidation

IN a series of recent papers by S. Glasstone and A. Hickling, the view has been put forward that hydrogen peroxide may be formed at the anode in aqueous solutions by the combination of discharged hydroxyl radicals, and some examples of electrolytic oxidation have been explained in this way. If this is the case, it might be expected that an anode would exhibit some of the apparent reducing properties of hydrogen peroxide, notably in reducing acidified solutions of permanganate and dichromate. Large effects are not to be anticipated, since the rate of spontaneous decomposition of the peroxide at an anode is high, and there is the possibility that any reduction which occurs may be masked by re-oxidation. The point has been investigated (A. Hickling, *J. Chem. Soc.*, 1453; 1936) and the predicted effects, although small, have been observed, so that the interesting result of apparent reducing properties of an anode has been established. The general method was to collect the oxygen evolved at the anode under consideration along with hydrogen from the cathode in a separate voltameter in series, and to show that the oxygen–hydrogen ratio is greater than that, 0·500, expected for the electrolysis of water. In the case of permanganate, the ratio was above 0·65 for favourable current densities, whilst in the case of dichromate a smaller but definite increase was observed. Other possible explanations are discussed, but the author considers them less probable than the one given above.

Impulse Voltages for Transformer Testing

THE apparatus required to get the high voltages necessary in order to test the devices used on the Grid is very expensive. An alternator which can produce a million volts for breakdown tests is not only expensive but also requires a large laboratory in which to operate. A simpler way of getting a million volts is to charge a hundred high-tension condensers in parallel to 10,000 volts, then connect them in series and so get a million volts between the electrodes. The apparatus necessary is much cheaper and the cost of operating much less. It has, however, the drawback that, as Kelvin pointed out many years ago, the discharge in certain cases is oscillatory, and so the maximum electric stress on which the breakdown depends is difficult to compute. A paper was read on this subject by Dr. T. E. Allibone, D. B. McKenzie and F. R. Perry before the Institution of Electrical Engineers on November 5. They have analysed theoretically and experimentally impulse voltages of varied wave-shapes applied to transformers having different winding characteristics, and obtained good agreement between theory and experiment. Hence tests of this nature should be of use in testing apparatus for use with the Grid so as to find out the effect of surge voltages and probably improve the continuity of the service. Tests of this nature have been employed for some years both in Switzerland and Germany which have enabled the engineers to improve their transformers. Further tests are in progress both in the United States and Great Britain, and the method of the authors in checking the theoretical results by means of oscillographic records promises to be of great value.

Air Locks in Aeroplane Fuel Systems

As a possible explanation of one type of failure of aircraft engines, the presence of an air or vapour lock in the fuel system and its prevention have been studied at the Royal Aircraft Establishment, and a discussion of the subject, the nature of the investigation, and the conclusions reached are now published (Air Ministry: Aeronautical Research Committee. Reports and Memoranda, No. 1693 (2237): Air and Vapour Locks in Fuel Systems. By M. A. A. Allfrey. Pp. 14+9 plates. London: H.M. Stationery Office, 1936. 1*s*. 3*d*. net). Several unavoidable causes operate to enable air to collect in the petrol pipe line, and in order to ensure the release of such bubbles as might, from any such cause, be entrapped, experiments were made by introducing air into glass pipes down which petrol was flowing under conditions comparable with those in practice. These showed that perfection of venting can be attained either by so building the pipe system that the air vents upwards at all flows, in which case the critical flow at every point is greater than the maximum demand of the engine, or by arranging that the critical flow never increases downwards. The first alternative being impracticable in that it requires pipes and cocks of excessive size, the second, which leads to an ideal system, was investigated, and the report sets out in detail the results and recommendations essential to its successful incorporation in petrol pipe lines, distinguishing between those applicable to air locks and those found to be successful in preventing locks caused by evaporation of the fuel itself, which is liable to give trouble at great heights.

Chemical and Physical Basis of Pharmacological Action

A JOINT discussion in which pharmacologists and chemists took part was organized by the Royal Society at Burlington House on November 12.

Prof. A. J. Clark opened the discussion with a general review of the difficulty of obtaining quantitative pharmacological data and of interpreting these data when obtained. The observations are subject to large errors, and the results are affected by so many factors that it is usually possible to explain them in several different ways. It is never possible to obtain formal proof of any one explanation, but in many cases the analogy between the action of drugs on living organisms and their actions under simpler conditions is close enough to establish a strong presumption as to the mechanisms involved. The most hopeful line of approach lies in the study of the form of the curve connecting the concentration of a drug with the magnitude of its effect after dynamic equilibrium is obtained. Such concentration-action curves can be divided into three distinct classes:

(1) It has been shown, in many cases, that the relation between the concentration of adrenaline, or acetylcholine, and its action on an isolated piece of muscle is accurately expressed by a hyperbola. This relationship can be interpreted in terms of mass action. If the drug, present in large excess, combines reversibly with a limited number of receptors in the muscle, simple calculations suggest that the curve connecting concentration and uptake would be a hyperbola. It is only necessary to assume that the effect on the muscle is directly proportional to the number of receptors acted on by the drug. Similar calculations have been used to explain quantitatively the uptake of gases by adsorbents, of oxygen by hæmoglobin, and of poisons by enzymes.

(2) Concentration-action curves for narcotics are usually nearly linear for small concentrations, and resemble closely the curves connecting the concentration of these substances with their effect on surface tension. Since the active narcotics are those which have most effect on surface tension, it is probable that this relationship is not fortuitous. Similar curves are obtained for the action of certain drugs on enzymes.

(3) In certain cases the concentration-action curve for effects, both on living tissues and on enzymes, is *S*-shaped. This can be interpreted as an irreversible all-or-none action on a collection of cells or other elements, the accessibility, or sensitivity, of which varies.

These three types of curve are found not only in the study of the action of drugs on isolated tissues and on enzymes, but also among the 'characteristic curves' which show the relationship between the dose of a drug and the percentage mortality which it causes in a large group of animals.

These curves were also discussed by Prof. J. H. Gaddum. It is true that, when characteristic curves are plotted on an arithmetic scale of doses, the curves may be either symmetrical or asymmetrical. When they are plotted on a logarithmic scale of doses, they are always approximately symmetrical. This fact is an example of the general law, which is justified both by theory and in practice, that the logarithm of any biological measurement is more likely to be normally distributed than the measurement itself (Galton, 1879). These facts are exemplified by the work of Hemmingsen (*Vidensk. Medd. fra Dansk naturh. Foren.*, 98, 125; 1934) who showed that the logarithms of the measurements of different species of animal in one phylogenetic group are normally distributed. Curves were shown in which the effect of drugs on isolated tissues, and on enzymes, and the effect of oxygen on hæmoglobin, were plotted both on arithmetic, and on logarithmic, scales of concentration. Plotted in these ways, all these curves looked similar to the characteristic curves, and it was suggested that the shape of the curves might be explained in terms of variations among the cells in the isolated tissue, or the protein molecules in the enzyme or the hæmoglobin.

Prof. W. Straub, of Munich, said that it is premature to speculate on the mechanisms behind the action of drugs until more is known of the actual effects produced. The central problem lies in the fact that atropine will act only on cells of a certain kind, and has no apparent action on all the other cells in the body. Some of the facts are illustrated by the inhibitory action of muscarine on the frog's heart. The action takes only a fraction of a second to develop, and when the solution is changed the heart recovers in a few seconds. If the muscarine is left in contact with the heart it diffuses into the heart. When diffusion ceases, the heart recovers from the inhibition. At this stage, the heart contains large quantities of muscarine. Inhibition only occurs while there is a potential gradient, or concentration gradient of muscarine, and the drug is diffusing into the heart. Drugs which act like this are called *potentialgifte*. Acetylcholine and adrenaline act as *potentialgifte*, but these two drugs, being natural constituents of the body, are destroyed in the cells, so that they can go on diffusing for long periods without the gradient disappearing. This is the reason why these substances can cause prolonged effects if the external concentration is maintained.

According to Prof. R. A. Peters, the time has come to replace the old biochemical concept of the cell as an unorganized colloidal solution by one of the cells as a co-ordinated structure. In 1929 he postulated what J. Needham has since called a cyto-skeleton for cells: by this he means a three-dimensional mosaic throughout the cell, composed of a network of protein molecules, the surface proteins being connected with the nuclear proteins by threads of cytoplasmic proteins. The amino and carboxyl groups of protein must play an important part in this pattern. The organization envisaged is submicroscopic; it provides the cell with means for independent and localized reactions, and is the cellular counterpart of a nervous system. Since these ideas were put forward, a clearer picture of the sort of organization which might exist has been obtained by the work on the X-ray structure of proteins, on surface films and by such protein models as those suggested by Drs. D. Wrinch and Jordan Lloyd. The cell contents appear to correspond more closely to a thixotropic gel than to a simple solution. Some enzymic systems appear to be structurally related, for example, the lactate and pyruvate system in brain. The cellular organization proposed might allow drug action to be explained in chemical terms, drugs reacting with specialized features of the cell structure.

Dr. J. F. Danielli discussed the structure of cell surfaces. The simplest possible concept of the cell plasma-membrane which is compatible with permeability data, surface tension data, and wetting properties, consists of a lipoid layer at least two molecules thick, with an adsorbed protein layer at each oil-water interface. The external oil-water interface must have an excess of acidic groups. Points of interest in this conception from the aspect of drug action are : (*a*) the excess acidity of the surface, which may be modified by surface active acids or bases ; this change will in turn affect the adsorbed protein layer, enzyme activity at the surface, and the permeability of the lipoid layer ; (*b*) the potential gradient at the interfaces, which will be of the order of 10^7–10^8 volts/cm. ; (*c*) the kinetics of penetration of such a membrane provide for high temperature coefficients for the simple process of penetration of the membrane by a drug, which may mask the temperature coefficient of drug action ; (*d*) it is of interest to know whether the enzyme centres on the cell surface are arranged in an organized fashion. This can be done by using poisons of the type A'–$(R)_n$–B' where A' and B' are specific poisons for the centres of type A and B. If there is any typical distance between A and B, there will be a sudden increase in efficiency of the poison for a particular value of n.

Dr. J. H. Quastel described the experiments with isolated pieces of tissue which have led him to the conclusion that the action of narcotics on the brain is due to their action on carbohydrate metabolism. Luminal reduces the oxygen consumption of slices of brain. It is particularly effective when glucose, lactic acid, or pyruvic acid is used as a substrate. It has no action on the oxidation of glutamic acid or succinic acid. Other narcotics have a similar action, and among narcotics of one type those which are powerful narcotics are also powerful reducers of oxygen consumption. The effect is reversible. The concentrations present in the blood during narcosis would be sufficient to have an action on the oxygen consumption of slices. Slices of tissues other than brain are less sensitive to narcotics. The action of narcotics on slices of brain is antagonized by potassium, but is not affected by calcium. The temperature coefficient of the effects on isolated slices is large ($Q_{10} = 6 \cdot 6$) as is also the temperature coefficient of narcosis in the whole animal.

It was pointed out by Dr. H. R. Ing that the pharmacological properties of many drugs have been shown to depend on definite functional groups or combinations of groups. The recognition of such pharmacologically active groups is exploited in chemotherapy. Some hormones and vitamins have also been shown to contain such groups. Aliphatic narcotics do not appear to contain active groups, and consequently the drug action must depend primarily on their physical properties. Drugs with active groups of quite different structure may also show similar pharmacological properties. When gross physiological changes, for example, the death of bacteria, are involved, several mechanisms may achieve the same gross effect ; but it is difficult to account for drugs so unrelated chemically as muscarine and pilocarpine acting selectively at the same sites and producing similar results. Again, drugs of the same structural type may have different actions, for example, butyl trimethyl ammonium augments, but octyl trimethyl ammonium antagonizes the action of acetylcholine on the frog's auricle.

Pharmacologically active groups seem to imply a chemical mechanism for drug action. The difference in the activity of stereo-isomeric drugs also suggests chemical combination of the drug with receptor molecules in tissues. Homologous series of drugs frequently show maximum activity for one member of the series, for example, alkylcresols, alkylamines, etc. In these cases, the activity may represent the summation of two opposite effects, depending on at least two physical properties. Other factors may be involved, such as the length of chain between two active groups, but in some series, for example, choline esters, the relatively high activity of one member is difficult to account for on these simple lines.

The factors affecting the action of chemotherapeutic drugs on Protozoa were discussed by Prof. Warrington Yorke. *Trypanosoma rhodesiense* is normally resistant to organic arsenicals, but when it is passaged through mice, there is a change in its morphology, and it becomes not only more pathogenic for mice, but also more sensitive to arsenicals. Similar changes occur more slowly when it is passaged through guinea pigs. *T. gambiense*, on the other hand, is comparatively easily killed by drugs, but if infected mice are treated with ineffective doses of organic arsenicals or antimonials or with acridine dyes, the Protozoa become resistant to all drugs of these classes. They remain sensitive to arsenious acid, tartar emetic and Bayer 205. It has been found impossible to develop resistance to tartar emetic, and difficult to develop resistance to Bayer 205. This artificially produced resistance differs from the natural resistance of *T. rhodesiense*, since it survives prolonged passage through mice and tsetse flies.

These facts represent a real danger in Africa, where these drugs are being injected into whole populations of people without proper precautions to ensure that the treatment is always continued until it is effective. It is probable that a strain of trypanosomes is being developed which will resist treatment. Later in the discussion, however, Dr. C. M. Wenyon gave reasons for believing that this development of immunity is due to the selection of resistant trypanosomes.

Sir Henry Dale, in opening the general discussion, expressed the belief that quantitative studies can only give superficial information. He agreed with Prof. Straub that the most important problem is the explanation of the fact that certain drugs affect certain tissues in very low concentrations and have no action on other tissues.

Among those who made impromptu contributions was Dr. F. Hawking, who discussed the effect of chemical structure on the action of organic arsenicals consisting of a benzene ring, a side chain containing arsenic, and a second side chain. The absorption of such substances by trypanosomes can be demonstrated. Trypanosomes which are resistant to treatment *in vivo*, fail to absorb substances containing the second side chain. Similar substances containing no second side chain are taken up, even by undamaged resistant trypanosomes.

Sir Rickard Christophers, discussing the chemical structure of antimalarial drugs, pointed out that it is difficult to predict the action of new substances. This is perhaps because insufficient attention is given to the physicochemical properties of these substances.

Preliminary measurements of solubilities and of pK's might discriminate between substances worth testing and those which would be useless.

Prof. R. Robinson asked why it is that plants so often contain alkaloids with marked actions on animal tissues. This may be explained by some theory of the biological history of the animals and plants which have developed together, or it may be due to the fact that the alkaloids are probably degradation products of proteins, since their structure can usually be derived formally from the naturally occurring amino acids.

Magnetic Properties of the Nickel-Iron Alloys

IN a pamphlet issued by the Bureau of Information on Nickel of the Mond Nickel Co., Ltd., Millbank, S.W.1, an account is given of nickel-iron alloys and their characteristics which will be of special value to electrical engineers and manufacturers.

The magnetic properties present very striking contrasts. The permeability of pure iron, for example, is gradually reduced by additions of nickel exceeding ten per cent, until in the region of 30 per cent the alloys are completely non-magnetic. Further additions of nickel give a range of alloys containing 35–85 per cent of nickel, which have a very high magnetic permeability and are in fact the softest materials magnetically that are commercially available. New alloys have now been developed by adding substantial proportions of nickel and aluminium, which are very hard and form permanent magnets of great strength. The 25 per cent nickel steel is characterized by an extremely high ductility and is corrosion resisting. It is practically non-magnetic and is used extensively in electrical engineering.

The group of iron alloys having 35–80 per cent of nickel, on account of their high permeability, are of great commercial importance. In 1921 the Western Electric Co. of America took out a patent for an alloy consisting of 78·5 per cent nickel and 21·5 per cent iron, all impurities being kept as low as possible. The heat treatment necessary consisted in heating the alloy to 900° C. and then cooling at a definite rate. The alloys patented by this company are given the general name of 'permalloy'. Since then, patents have been taken out for other nickel-iron alloys, containing small proportions of other elements. 'Mumetal', patented by the Telegraph Construction and Maintenance Co., Ltd., London, is one of these. It contains 6 per cent of copper, which facilitates heat treatment and stabilizes the alloy.

The first use to which the high permeability alloys were put was for the 'loading' of submarine cables. In accordance with Heaviside's theory, this would prevent distortion of the signals and also their attenuation. Simultaneously with the development of the loaded submarine cable, continuous attention was given to long-distance land line cables, and nickel-iron devices were found very helpful. Afterwards, in order to save space, it was found advantageous to employ the magnetic alloy in the form of dust or powder. Various chemical and physical methods are used to produce the alloy in this form. A drawback is that the powder has very low permeability, but the energy losses in it are much smaller.

In the year 1930, news first came from Japan of the discovery of a new series of permanent magnet alloys in which the principal alloying elements were nickel and aluminium. Since their introduction, these new magnet steels have been intensively studied, and they are now superseding the cobalt and other steels previously used for these applications. These alloys offer the maximum magnetic energy per unit volume yet available to manufacturers. One of the most important applications of the new magnets is for radio loud speakers. In the manufacture of small motors, magnetos and other small-sized dynamo electric equipment, the nickel alloy magnets are found very efficient and adaptable. They are used in the magnetic detectors used in 'automatic' traffic signalling.

On the theoretical side, our knowledge of magnetic alloys is far from complete. When we have a better knowledge of how heat treatment affects them, still more useful alloys may become available.

Educational Topics and Events

CAMBRIDGE.—The Vice-Chancellor has received a letter from Sir Harry McGowan, chairman of Imperial Chemical Industries, Ltd., stating that it is not proposed to continue to support financially the work on molecular rays carried out since 1929 by Mr. R. G. J. Fraser, who has now been appointed to the research staff of I.C.I. (Alkali) Ltd. The apparatus and equipment installed, at a cost of about £2,500, is being offered to the University for the use of the Departments of Chemistry and Physics, and Sir Harry hopes that it will continue to be used for research on molecular rays.

The Managers of the Benn W. Levy Fund have appointed K. P. Harrison, of King's College, to the studentship in biochemistry.

J. H. Gaddum (Trinity College), W. B. R. King (Magdalene College) and Dr. O. M. B. Bulman (Sidney Sussex College) have been approved for the degree of Sc.D.

The Governing Body of Emmanuel College invites applications for a research studentship which will be awarded in July 1937. Preference will be given to candidates who have already completed one but not more than two years of research. The studentship, which must be held at Emmanuel College, and has a maximum annual value of £150, is awarded and normally held for two years, but may be renewed for a third. Further information can be obtained from the Master of the College.

LONDON.—The title of professor of pathology of mental disease in the University has been conferred on F. L. Golla, in respect of the post held by him at the Maudsley Hospital; that of professor of psychiatry in the University on Dr. Edward Mapother, in respect of the post held by him at the Maudsley Hospital, and that of reader in mathematics in the University on Dr. L. S. Bosanquet, in respect of the post held by him at University College.

The following doctorates have been conferred: D.Sc. in botany on H. Chaudhuri (Imperial College—Royal College of Science); D.Sc. in horticulture on R. G. Hatton (East Malling Research Station); D.Sc. in physics on F. C. Chalklin (King's College).

Prof. F. A. Cavenagh has been appointed, as from September 1, 1937, to the University chair of education tenable at King's College. Since 1934, he has been professor of education in the University of Reading.

OXFORD.—In Congregation on November 21 the honorary degree of D.C.L. was conferred upon the American Ambassador, Mr. R. W. Bingham, and on J. L. A. Avenol, secretary-general to the League of Nations.

Dr. W. Stephenson, assistant director of the new Institute of Psychology, has been given the degree of M.A. by decree.

Convocation and Congregation, with Lord Halifax, the Chancellor, as president, assembled in the Divinity School on November 24 to assist at the promulgation of the decree respecting Lord Nuffield's benefaction to the Medical School. Speeches were made conveying the thanks of the University for his magnificent gift. The most dramatic speech, however, was made by Lord Nuffield himself in which he announced that he proposed to raise the original sum of £1,250,000 to £2,000,000. This sudden and quite unexpected announcement was received with a curious mixture of astonishment and gratitude. The trustees of the new trust will consist of a chairman and three others nominated by Lord Nuffield, the vice-chancellor and another member of Hebdomadal Council, the professor of medicine, and three representatives of the two hospitals in Oxford concerned in the scheme. There will also be a committee for carrying out the scheme in detail—the vice-chancellor, the professor of medicine, the director of the Nuffield Institute, three members of the faculty of medicine, three representatives of the hospitals, and the four new Nuffield professors of surgery, clinical medicine, anæsthetics, and obstetrics. The new professors are to be appointed as soon as practicable and already their chairs have been allotted to four colleges. The mode of their appointment, and the regulations governing them, will be very similar to those affecting other professors. The salary attached to each chair, however, will be £2,000 a year. The new professors may not engage in private practice but they will be allowed to receive fees from some of the patients they attend in the hospitals associated with the scheme.

THE University of Leyden has been awarded a sum of 20,000 dollars by the Rockefeller Foundation for researches to be made in the course of five years on infantile psychology.

ON the proposal of the Minister of Public Health, the Belgian Government is to create a second Superior School of Physical Education at Liège similar to that attached to the medical faculty of Ghent.

AT the reopening ceremony of the University of Paris held in the great amphitheatre of the Sorbonne on November 7, in the presence of M. Albert Lebrun, President of the French Republic, the Minister of Education and the Rector of the University, the degree of doctor *honoris causa* was conferred on Dr. Israel Holmgren, professor of physiology at the Caroline Institute of Stockholm, and on Prof. George David Birkhoff, professor of mathematics at Harvard University.

Science News a Century Ago

Schönbein and Faraday

ON November 26, 1836, Schönbein wrote from Basle to Faraday: "The Philosophical Society of Bale in one of their last meetings elected you their honorary member and I am charged by our President to forward the diploma and ask you the favour to accept of the latter as a weak expression of the high esteem which our Society entertain for you, on account of the eminent services you have rendered natural Science". Schonbein then went on to refer at length to his own observations of the behaviour of iron wires in acids, and concluded his letter by remarking: "Before closing this letter, I take the liberty to ask you a favour. Our Establishment wants to get a good magnetic-electrical Machine, by means of which the principal experiments on Magneto-Electricity may easily be made in classes. Now if it be not too much asked, the Committee of our Museum should feel themselves laid under great obligations to you, would you be so kind as to order such an apparatus to be sent to us by a London instrument-maker."

Berzelius awarded the Copley Medal

AT the anniversary meeting of the Royal Society held on November 30, 1836, the president, H.R.H. the Duke of Sussex, returned to the chair, after an absence of two years owing to severe eye trouble. The report of the proceedings of the Council, read by the secretary, said "The Council have awarded a Copley Medal to Baron Berzelius for his application of the Doctrine of Definite Proportions in Determining the Constitution of Minerals. To the labours of this distinguished chemist, science is indebted for many of the facts by which the Laws of Definite Union were established. As early as 1807, soon after Dalton and Gay-Lussac had made known their views on this vital branch of chemistry, Berzelius commenced an elaborate examination on the proportions in which the elements of compound bodies are united, beginning with the salts, and subsequently extending his researches to all other departments of his science, as well to the produces of organised existences as to those of the mineral world. . . . His numerous analyses of minerals enabled him at once to elucidate their nature through the light derived from the laws of definite combination, and at the same time to supply in the composition of minerals a splendid confirmation of those laws. . . ."

As had been the case in 1821, 1825, 1827, 1832, a second Copley Medal was awarded, Edward Kiernan receiving the medal for his discoveries relative to the structure of the liver. "Before the researches of Mr. Kiernan," the report said, "the liver was supposed to consist of two dissimilar substances. . . . The relation of the vessels and excretory ducts to those supposed dissimilar substances was not known. . . . Mr. Kiernan's discoveries show that in place of two textures there exists but one, but that the difference in colour results from the accidental congestion of one or other of the system of vessels which are found in the liver. He has demonstrated the size and limits of the internal glandules of which the liver consists; has traced the relation to these glandules of the different orders of vessels, which are distributed through the organ and has explained the mechanism of biliary secretion."

Pierre-Simon Girard (1765–1836)

On December 1, 1836, the eminent French civil engineer Pierre-Simon Girard died in Paris at the age of seventy-one years. Born in Caen on November 4, 1765, he was trained as an engineer and in 1792 attracted attention by his essay on "Locks for Navigation", for which he was awarded a prize by the Paris Academy of Sciences. Thus brought into notice, he was chosen with Monge, Berthollet, Fourier and other scientific men to accompany Napoleon to Egypt, and became one of the members of the short-lived Institute founded in Cairo. On his return to France, he was appointed engineer-in-chief of the Canal de l'Ourcq and entrusted with the water supply of Paris. His "Recherches sur les Eaux Publiques de Paris" published in 1812 contains a historical account of the water supply of the city. Girard was elected a member of the Academy of Sciences in 1813 and six years later superintended the installation of a gas supply for the streets and theatres of Paris.

Opium Eating and Health

In a lecture on opium eating published in the *Lancet* of December 3, 1836, Dr. George G. Sigmond remarked that a very interesting question had arisen as to the effect of the habit on health and on longevity. He instanced the case of the late Earl of Mar, who had insured his life in an Edinburgh office to a large amount. Although he consumed two to three ounces of laudanum daily, he did not state the fact when he obtained the policy of insurance, and on his death from jaundice and dropsy two years later, the company declined payment of the policy on the grounds that his lordship had concealed from them a habit which tended to shorten life. The bank that held the policy as security for money lent entered on an action, with the result that the insurance office had to pay the amount, not, however, on the ground that the habit was fatal to life, but because the office had not shown the proper degree of caution when the insurance was effected.

St. James's Ornithological Society

In the last part for 1836 of the quarterly journal the *Analyst* (5, 314), under the heading "St. James's Ornithological Society", it is stated that "this Society is instituted for the purpose of forming a collection of water birds in the garden of St. James's Park; and its operations will subsequently be extended to the waters in the other parks, if the funds of the Society be found sufficient. The first object will be to exhibit a complete collection of British Anatidae, both resident and migratory. . . . It is intended to keep the whole, as far as practical, in a state of nature, and the collection, being formed in the public parks, will, of course, be open to the view of every one. As there is in London no other exclusively Ornithological Society, it is unnecessary to point out to the ornithologist the advantages which may result from an institution possessed of a locality so admirably calculated for a collection of aquatic birds, and for affording facilities for observations on the changes of plumage from sex, age, or season, which are so interesting to Naturalists, and so difficult to be observed elsewhere."

The Earl of Liverpool was president of the Society, and its proceedings were sanctioned by the Commissioner for Woods and Forests.

Societies and Academies

London

Royal Society, November 19.

W. A. Bone and L. E. Outridge: Some influences of dilution on the explosive combustion of hydrocarbons. Certain effects are dealt with of dilution with inert gases (Ar, He and N_2) upon explosions of equimolecular mixtures of ethylene, or acetylene and oxygen, such as $C_2H_4 + O_2$ and $C_2H_2 + O_2$ which normally give rise to carbonic oxide and hydrogen, without any separation of carbon or steam-formation in accordance with the equations:

$$C_2H_4 + O_2 = 2CO + 2H_2,$$

and

$$C_2H_2 + O_2 = 2CO + H_2,$$

respectively. Chemical, photographic and spectrographic tests show that sufficient dilution of such media, while not much affecting the main result, may induce some secondary carbon deposition and steam-formation on explosion, when the mean flame temperature is thereby reduced to a point well below 2,000° C., such result being probably due to the fall in flame temperature induced by dilution.

W. Payman and W. C. F. Shepherd: Explosive waves and shock waves. (4) Quasi-detonation in mixtures of methane and air. Experiments on a small and on a large scale have been carried out to investigate the possibility of detonation in mixtures of methane and air. In small-scale experiments the resulting explosion is in some respects similar to detonation; but it is unlike detonation in that the speed is not uniform and in that the wave or flame front is partly sustained first by the flame and then by hot particles from the detonator. The explosion is described as 'quasi detonation', since the energy maintaining the wave is not wholly derived from the combustion of the methane. An explosion which is similar to detonation was also established in large-scale experiments in which a 9·1 per cent methane-air mixture was contained in a gallery 30·5 cm. in diameter and ignited by means of a charge of high explosive. This quasi-detonation is propagated through quiescent mixture at a uniform rate of 1,900 metres per second, and the flame is intensely luminous and accompanied by high pressure.

Paris

Academy of Sciences, November 3 (*C.R.*, 203, 833–900).

Edouard Chatton and Félix Villeneuve: The evolutive cycle of ***Eleutheroschizon Duboscqui***. Experimental proof of the absence of schizogony in this form and in ***Siedleckia Caulleryi***.

Paul Delens: The anallagmatic geometry of the tetrahedron.

P. Bonét-Maury: A manometer for high vacua. A modified manometer of the Knudsen type.

Pierre Chevenard: A very small testing machine with photographic recording, and its application to the study of textile fibres. The machine is constructed to test single fibres, with a maximum load of 50 gm. The record shows the relation between elongation and load.

Jean Chazy: The almost circular movements due to a nearby force of Newtonian attraction.

Emile Sevin: The influence of a magnetic field on the atom of hydrogen.

Roger Mérigoux: The movement of contaminated liquid surfaces.

Félix Ehrenhaft: The experimental determination of the mobility of small spheres in a gas.

Arcadius Piekara and Bruno Piekara: Electrical saturation in pure liquids and their mixtures. Study of the influence of the electric field on the dielectric constant of mixtures of benzene and nitrobenzene at varying concentration. The effect of traces of moisture.

Ouang Te-Tchao: Counting particles in suspension in air.

Gabriel Foex and Charles Fehrenbach: The calculation of the magnetic moment of the ions.

Ny Tsi-Zé and Weng Wen-Po: The absorption spectrum of cæsium.

Georges Bruhat and Pierre Guénard: Study of the circular dichroism of solutions of camphor in water and in acids.

Théodore V. Ionescu: The structure of the photon.

Louis Cartan: The application of the methods of electronic optics to mass spectrography.

Robert Tréhin: The application of certain physical methods to the search for complex compounds in solution. The variation of a physical property of a liquid mixture with the composition is frequently used for detecting the formation of a complex compound. The method fails when more than one complex compound is present, and generally it is not possible to prove or deny the existence of such compounds on such evidence alone.

Guillaume Rumeau: Optical antipodes and velocities of crystallization.

Mordechaï Bobtelsky and Mme. Ljuba Bobtelsky-Chajkin: Mixed catalytic effects in the decomposition of hydrogen peroxide in the presence of sodium tungstate and other catalysts.

Marc Antoine Foex: The action of hydrogen on alkaline glasses at a high temperature. Alkaline glasses suffer marked loss of weight when heated in hydrogen at 850°–1,150° C., and this is due to loss of alkali.

Mlle. Marie Falinski: Study of the system ZrO_2–SO_3–H_2O. The conditions for the existence of a new acid zirconium sulphate, $Zr(SO_4)_2,H_2SO_4,2H_2O$.

Mme. Léone Walter-Lévy: Contribution to the study of the double decomposition between solutions of magnesium sulphate and potassium carbonate at the boiling point.

Henri Lefebvre and R. Faivre: Contribution to the study of the oxidation of coal. At temperatures between 150° and 300° C., oxygen rapidly penetrates coal, especially the vitrain. The coal becomes poorer in hydrogen and more resistant to oxidation.

Jean Feldmann and Robert Lami: The growth of the mangrove at Guadeloupe.

Jean Chaze: Intoxicating rye-grass (*Lolium temulentum*) and the pure culture of its endophyte.

Joseph Magrou: The culture and inoculation of the symbiotic fungus of *Arum maculatum*, the cuckoo-pint.

Yves Le Grand: Binocular vision through crossed polarizers.

Albert Vandel: The appearance of colourless mutations in *Trichoniscus* (*Spiloniscus*) *elisabethæ* and their hereditary behaviour.

Paul Meunier: The presence and distribution of aluminium in animal tissues. Aluminium is always present in animal tissue, but in much smaller proportions than in plants.

Albert Peyron and Henri Limousin: Intravascular polyembryony and the metastases with multiple tissues in the embryomes of the testicle.

André Lwoff and Mme. Marguerite Lwoff: The physiological role of the co-dehydrogenases for *Hæmophilus parainfluenzæ*.

Constantin Levaditi, Carl Kling, Mladen Païc and Perez Haber: The approximate size of the poliomyelitic virus.

Washington, D.C.

National Academy of Sciences (*Proc.*, 22, 525–566, Sept. 15).

Ernst Öpik: Meteor heights from the Arizona Expedition. About 22,000 meteors were observed between October 1931 and July 1933; of these, 3,540 were observed simultaneously from two stations and their heights could therefore be calculated. 80 per cent of the objects observed were sporadic meteors and only 7 per cent belonged to the major showers. It is deduced that meteors meeting the earth are vaporized 23 km. higher than those overtaking the earth, due to greater relative velocity. Seasonal variation of height suggests an annual fluctuation of height of the atmosphere of amplitude 3·7 ± 0·7 km. There is no evidence of a hydrogen atmosphere, at least to a height of 130 km.

A. W. Bellamy: Inter-specific hybrids in *Platypœcilus*: one species *ZZ–WZ*; the other *XY–XX*. The results are discussed from the point of view that there is a single sex differential which prejudices development in the direction of maleness or femaleness.

G. W. Beadle and Boris Ephrussi: Development of eye colours in *Drosophila*: transplantation experiments with suppressor of vermilion.

G. A. Miller: Groups containing a relatively large number of operators of the same order.

John H. Lawrence, Paul C. Aebersold and Ernest O. Lawrence: Comparative effects of X-rays and neutrons on normal and tumour tissue. Normal healthy albino mice and pieces of an easily transplantable mouse tumour (Sarcoma 180) were submitted to filtered 200 kv. X-rays and to neutrons from the cyclotron, the doses of the two types of radiation being measured in r units by a Victoreen condenser type r meter. After irradiation, the tumour tissue was implanted into susceptible mice and its development watched. It is concluded that, per unit of ionization, neutrons are much more effective than X-rays in destroying normal mice *in vitro* and Sarcoma 180 *in vitro*.

F. Zwicky: Characteristic temperatures in supernovæ. A theoretical discussion.

Carroll C. Pratt: Interaction across modalities: simultaneous stimulation. A lowering of the apparent pitch of musical instruments in a concert hall on dimming the illumination has not been generally remarked. Conversely, an experimental test in which observers compared an illuminated source with a previously illuminated standard source while listening by ear-phones to a high- or a low-pitch tone, showed no significant influence of the sound stimulus on the estimates made of the illumination of the light source. It seems unlikely that two psychological events from different modalities, operating at a sensory level, will influence each other.

Forthcoming Events

[*Meetings marked with an asterisk are open to the public.*]

Monday, November 30

Royal Geographical Society, at 8.30.—Lincoln Ellsworth: "A Recent Flight across Antarctica".

Tuesday, December 1

Royal Society of Arts, at 4.30.—Brigadier J. G. Browne: "The Assyrians".

Pharmaceutical Society of Great Britain, at 8.30.—(in the Great Hall, University College, London, W.C.1).—J. Davidson Pratt: "The Defence of the Civil Population against Gas".

Wednesday, December 2

Institution of Heating and Ventilating Engineers, at 7.—(at the Institution of Mechanical Engineers, Storey's Gate, S.W.1).—Dr. M. C. Marsh: "Humidity in Industry".

Friday, December 4

Society of Chemical Industry (Liverpool Section).—Prof. I. M. Heilbron: "Modern Technique in Biochemistry" (Hurter Memorial Lecture).

King's College, London, at 5.30.—Dr. J. Johnson: "Methods of Excavations for Greek Papyri in Egypt".*

Royal Institution, at 9.—Sir Stephen Gaselee: "Natural Science in England at the End of the Twelfth Century".

British Institute of Radiology, December 2–4.—Annual Congress and Exhibition to be held in the Central Hall, Westminster, S.W.1.

The Indian Institute of Science

IT required the lessons of the Great War to bring home to those engaged in industry in Great Britain the benefits which accrue from scientific research. It speaks therefore highly of the acumen of the Parsee merchant, the late Mr. J. N. Tata, that forty years ago he proposed to endow an all-India Research Institute. After a careful consideration of the schemes drawn up by Sir William Ramsay, and by Sir David Masson and Colonel Clibborn, his plan came to fruition; and on a site at Hebbal, near Bangalore, given by the Government of Mysore, it was decided to proceed with the erection of the Institute. Unfortunately, Mr. Tata died in 1904, but his sons, the late Sir D. J. Tata and Sir R. J. Tata, gave effect to his wishes, and in 1906 the first director, Dr. Morris W. Travers, was appointed.

At the time when the scheme was first adumbrated, scientific research in India was confined almost entirely to the Government services comprised in the Survey of India, the Geological, Botanical and Zoological Surveys, and the various agricultural departments. With a few notable exceptions, mainly in the laboratories of Sir J. C. Bose and Sir P. C. Rây, the universities contributed little to the advancement of knowledge. The new institute filled, therefore, an obvious gap in the Indian educational system, providing for the first time facilities for the training of students in the methods of scientific research. The first students were admitted in July 1911 into the department of general chemistry (Prof. M. W. Travers), applied chemistry (Prof. Rudolf), and electrical technology (Prof. A. Hay), whilst in September of the same year a department of organic chemistry, under Prof. J. J. Sudborough, was added.

The exact functions of the Institute as set forth by Mr. Tata were somewhat vague, but the underlying idea was that it should work "for the benefit of India". It was naturally anticipated that the Institute would by its researches advance the development of Indian industries. The normal working of the Institute was upset in 1914 by the resignation of its first director, who was succeeded by Sir Alfred Bourne, and by the outbreak of the Great War, which naturally diverted its activities. On the retirement of Sir Alfred Bourne in 1919, it was felt that a clearer demarcation of the activities of the Institute was required, more especially since the Indian universities themselves were now active centres of research. In 1921 a committee, of which Sir William Pope was chairman, submitted a valuable report which recommended certain important changes. With the appointment of Dr. (now Sir) M. O. Forster as director, the Institute entered upon a fresh era, and although, as was perhaps natural, criticisms were heard, the period of his directorship, thanks to his great administrative ability and tact, was one of continued progress, numerous contributions of both scientific and industrial importance being made.

One of the recommendations of the Pope committee was that a reviewing committee should be appointed quinquennially to report on the working of the Institute, and a committee, of which Lieut.-Colonel Sewell was chairman, recommended in 1931 that greater attention should be paid in future to investigations likely to benefit Indian industries, since this appeared to be the desire of the founder. There has in the past been much criticism of the Institute, mainly in our opinion unfounded, on the grounds that the work carried out there was of purely scientific interest.

On the retirement in 1933 of Sir Martin Forster, the distinguished Indian physicist, Sir Venkata Raman, was appointed director. Sir Venkata was already well acquainted with the problems of the Institute since, not only had he been a member of the Pope committee, but he had served also on the council of the Institute. Since his appointment followed so soon after the report of the Sewell committee, it was naturally anticipated that he would endeavour to implement its recommendations and encourage industrial research. This has, however, proved far from being the case. As a physicist he has perhaps not unnaturally taken advantage of a recommendation of the Pope committee and developed a department of physics of which he himself is the head. Whilst this in itself was unobjectionable and a very necessary adjunct to a live department of physical chemistry, he would appear to have developed it at the expense of the existing departments, more especially those of general and organic chemistry. Simultaneously, considerable friction arose between the professorial staff and the director, resulting two years ago in the resignation of Profs. Watson and Mowdawalla.

We have now before us the report of the second quinquennial committee, presided over by Sir James Irvine, which was submitted to the Visitor (H.E. the Viceroy) last March and the recommendations of which have, we understand, been accepted in principle by the Council of the Institute. The committee found the internal affairs of the Institute to be in a most alarming condition, and to quote the report "the future of the Institute is evidently precarious". Brilliant as have been the contributions made by the director to physical science during the past four years, there is undoubted evidence that he has proved a signal failure as a director. Unlike his predecessors, he would appear to have interfered to an unwarrantable degree in the working of the various departments and rendered conditions so difficult that the resignations referred to above are readily understood. Further, he has seriously jeopardized the financial position, so that the budget can now only be balanced by drawing heavily upon reserves. It might be suggested that the Senate has been weak in allowing the continuance of the state of affairs now revealed, but it is doubtful if the protests, which it obviously made, were ever allowed to come before Council. Furthermore, the fact that two of the most important chairs, those of general and organic chemistry, were vacant, weakened its authority. If the present position had been allowed to proceed unchecked, there seems to be little doubt that practically the whole of the Institute's resources would have been devoted to the furtherance of research in pure physics, which, as the report remarks, would have been "a complete departure from the aims of the Founder".

Deeply impressed by the deplorable conditions now prevailing in the Institute, the Irvine committee makes far-reaching recommendations, some of which we print on page 981. These will, if adopted, make a complete change in the administration of the Institute, which is in many respects unnecessarily complex. Two outstanding features of the recommendations are (i) that the routine duties of administration, now in the hands of the director, should be entrusted to a registrar and (ii) that the Senate should have a direct representation on the Council. It is suggested that the registrar, who would be seconded from one of the civil services, should be secretary to the Council, Senate and Finance Committee and be responsible also for dealing with the correspondence of the Institute. This would eliminate the possibility, which at present exists, of the Senate's recommendations not being considered by the Council. Prior to the Pope committee, all heads of departments were members of the Council, and it is unfortunate that the direct representation of the Senate on the Council, a general feature in most British universities, should have been discontinued. The Council will be further strengthened, if the committee's recommendations are adopted, by the presence of a representative of the old students. This again is in accord with university practice in Great Britain.

A further recommendation of the committee is that staff appointments, in place of being for a limited number of years, should, after a probationary period, be continued until the age of retirement fixed by the Council. This once more is a reversion to the former custom, and should not only allow of a wider field of choice in making future appointments, but also enable present members of the staff to stand up for their rights and privileges.

The present unhappy position at the Institute has arisen largely from the defective administration of the director, and it is therefore natural that the Irvine report deals at length with methods for overcoming the present difficulties and preventing their recurrence. It discusses, however, the general working of the various departments in the Institute and it suggests certain economies which should result in the balancing of the budget. Whilst not desiring in any way to limit purely scientific activities, which are regarded as fundamental, the committee suggests how it should prove possible to develop research on industrial problems. The recommendation that an organic chemist of standing should be in charge of the departments of general and organic chemistry, with four assistant professors for various branches of the science, will meet with general approval. The committee comments severely, and in our opinion with reason, on the recommendation made by an economy committee that physical chemistry should be merged in the department of physics. In view of the fundamental and growing importance of physical chemistry to the chemical industries, it is amazing that such a recommendation should ever have been made. It is anticipated that, as funds become available, the various assistant professorships will be raised to the status of full professors.

We feel convinced that if the admirable recommendations of the Irvine committee are implemented, the happy spirit, which formerly prevailed at the Institute, will be restored. There is no doubt that, with a few desirable changes of organization, a competent director could lead the Institute to notable success; if, however, the director has not the confidence and trust of the staff, the Institute must fail of its essential purpose, however perfect the organization may be. Last July was the silver jubilee of the Institute: when the time comes to celebrate its golden jubilee we do not doubt that it will have justified the desire of its founder and will have worked "for the benefit of India".

European Civilization and the African

(1) Native Policies in Africa
By Dr. L. P. Mair. Pp. xi+312. (London: George Routledge and Sons, Ltd., 1936.) 12*s*. 6*d*. net.

(2) Reaction to Conquest:
Effects of Contact with Europeans on the Pondo of South Africa. By Dr. Monica Hunter. (Published, with the assistance of a Grant from the Carnegie Corporation through the Research Grant Board, Union of South Africa, for the International Institute of African Languages and Cultures.) Pp. xx+582+28 plates. (London: Oxford University Press, 1936.) 30*s*. net.

(3) Ten Africans
Edited by Margery Perham. Pp. 356+16 plates. (London: Faber and Faber, Ltd., 1936.) 15*s*. net.

IN affairs concerning native Africa the anthropologist is no longer, as a generation ago, a voice crying in the wilderness. An ever increasing literature offers studies of the problem of the native in a varying range and from various points of view; but the authors in the main are at one in making scientific investigation of native life and conditions the essential principle of argument in theory and practice. A further difference to be noted—and this is of no little importance in view of much misunderstanding—is that these scientifically trained students of native Africa argue with detachment. Unlike their predecessors, they neither play upon the strings of philanthropy, nor as anthropologists enter unqualified protests against the modification of custom, arguing that if preserved it might serve as material for scientific investigation. Recognizing that Africa cannot be kept as a museum piece, they accept the inevitability of change, and record the facts and appraise tendencies in relation to native institutions as social and economic phenomena *per se*. It follows, almost as a matter of course, that they are aloof from political prepossessions.

Of the three books under notice each serves to illustrate a distinct line of approach to the investigation of the effects of the impact of European civilization upon the character, the institutions and the mode of life of native Africa. Dr. Lucy Mair deals with the machinery of administration and the policies which have inspired its organization; Dr. Monica Hunter, following a more general convention, records and analyses the custom of an existing group, contrasting it with the conditions of an earlier period, as well as with the conditions of the urban population and dwellers on European farms; and Miss Margery Perham, in a series of autobiographies of individuals from contrasted environments in varying degrees of sophistication, exhibits in the round, the actual product of changing conditions at almost every stage between a 'savage' and a member (feminine) of the University of Oxford.

(1) Over Dr. Mair's book it is unnecessary to linger. Its scope and method call for little comment, while to discuss its subject matter adequately would call for no less space than the volume itself.

The policies, administrative methods and problems of the European powers in Africa are concisely summarized and discussed. British territory, as the most extensive and the most varied in method, naturally receives the most attention. Direct rule, segregation, the dual system and indirect rule, each is analysed in its environmental setting in turn and subjected to a criterion in which native well-being, native rights and native needs are the essential elements. Dr. Mair's book is an indispensable aid to anyone who seeks to understand the extremely complex question of native development and administration in Africa.

(2) The group selected by Dr. Hunter for investigation, the Pondo of South Africa, was not annexed to British rule until 1895. For the investigator they possess the advantage that not only have they suffered less change than most indigenous peoples of South Africa, but also there still survives among them a number of elders who remember ancient custom. Missionary effort, though of long standing and preceding annexation, has had less effect than the trader, also active before the coming of white administration. The vast majority of the Pondo are still pagan. The most potent influence, however, in bringing about change has been the demand for labour in the Union on farms, in the mines, and in other forms of industry. As natives now go, they are fairly prosperous; and the land question has not become acute as elsewhere. Conditions on the Pondoland reserve are contrasted with urban conditions in East London, S.A., where municipal regulations and conditions of employment have virtually eliminated native custom, especially in so far as cattle holding is impossible. On the European farms such institutions and customs as persist have, as a rule, suffered a radical modification.

Apart from its specific direction as a study of cultural modification, Dr. Hunter's book is a valuable contribution to the anthropological literature of South Africa. Her life-long acquaintance with the South African Bantu—she is herself a South African and was brought up at Lovedale—has been of the greatest service in admitting her to an understanding of the finer shades of meaning in custom and belief, which so frequently escape the no less highly trained, but less experienced observer.

(3) Miss Perham has added a few notes, but otherwise has scarcely touched the documents, which make up "Ten Africans". Her task has been that of selection, and the lives of the ten individuals here included have either been written by the subjects themselves, or have been reported verbatim. Not only are the narratives intensely entertaining in themselves, but for the social anthropologist they are also valuable raw material for judgment of the effects, psychological and other, of European contacts on the individual. The first life-history given here, for example, in which an aged member of the Babemba, who was brought up at the royal court, contrasts former conditions with those of to-day, incidentally affords a clue to weaknesses in the present system of administration, which sometimes has retained the form of native institutions, but has unwittingly destroyed the spirit which was its integrating force.

A Norse Settlement of the Viking Age in Greenland

Viking Settlers in Greenland:
and their Descendants during Five Hundred Years. By Dr. Poul Nørlund. Pp. 160. (London: Cambridge University Press; Copenhagen: G. E. C. Gads Forlag, 1936.) 7*s*. 6*d*. net.

FOR many years the attention of Danish archæologists has been directed to Greenland, not only by reason of the romantic history of the Norse settlement in that remote land, but also by the numerous remains of buildings—the farmsteads of the settlers, and their churches.

Brattahlid, believed to be the ruins of the homestead of Erik the Red, the first immigrant to go to Greenland from Iceland, in or about the year A.D. 985, was excavated and reported on by Dr. Nörlund and Dr. Marten Stenberger in 1934, and since then research has been carried on by Dr. Aage Roussell, whose account of his work under the title of "Sandnes and the Neighbouring Farms" has just been published.

Dr. Nörlund, in the volume under notice, has clothed with flesh and blood the dry bones of archæology, and told the story of the colonization of Greenland, and of the hard lives of the settlers in their valiant efforts to maintain themselves in an inhospitable land, utterly neglected by the Danish kings who claimed supremacy over this outpost of civilization. It is a sad tale of how the very monarchs who should have fostered and maintained the colony strangled its trade in the exercise of a monopoly, depriving the settlers of the necessities of their existence, and eventually bringing about the extinction of the colony. Dr. Nörlund estimates that in the 280 farms which there are said to have been, there must have been no fewer than three thousand inhabitants, and probably more when the settlement was flourishing. By the fourteenth century, privations were telling on the physique of the people, and they were being pressed by the Scraelings, as they termed the Esquimaux. In the fifteenth century, official communication with the mother land had entirely ceased. Neither the prelate, who bore the title of Bishop of Garda, nor merchants went thither, and by the commencement of the sixteenth century, the medieval Norse culture must have been entirely eradicated.

Dr. Nörlund's book is a fascinating tale, the record of a great adventure viewed from all its various aspects. It provides an admirable illustration of the life of a Norwegian settlement of the Viking age, when that robust people were the strongest sea-power in northern Europe, and the first navigators to reach the American continent, known to them as 'Vinland'.

Not the least interesting results of the research in Greenland was the discovery of numerous well-preserved garments in the frozen ground of an ancient cemetery, which was being gradually eroded by the sea. The dead had been shrouded in the clothes they wore when in life. The relics recovered by the explorers from the site filled twelve large cases. These garments, preserved in the National Museum at Copenhagen, form a unique collection of the everyday clothes of the ordinary folk of the Middle Ages.

To those interested in the recent discovery of Viking settlements in Orkney and Shetland, this book will be valuable as furnishing plans of contemporary houses and farm buildings, and by enabling them to realize to some extent how those Norse settlers lived, trading in furs of seal and otter, the produce of the islands, and cultivating their farms. It will help to eradicate the impression that the early Norse settlers on the shores of Britain were merely ruthless sea-rovers.

The book is fully illustrated, containing *inter alia* a series of illustrations of the Herjolfnes garments. The translation from the Danish has been well done, and the text is singularly free from typographical errors.

Modern Perfumes and Essences

(1) Perfumes, Cosmetics and Soaps: with Especial Reference to Synthetics. By William A. Poucher. Vol. 2: Being a Treatise on the Production, Manufacture and Application of Perfumes of all Types. Fifth edition. Pp. xiii+426+63 plates. 25*s*. net. Vol. 3: Being a Treatise on Modern Cosmetics. Fifth edition. Pp. xi+228. 21*s*. net. (London: Chapman and Hall, Ltd., 1936.)

(2) Flavours and Essences: a Handbook of Formulæ. By M. H. Gazan. Pp. vii+115. (London: Chapman and Hall, Ltd., 1936.) 25*s*. net.

(1) THERE can be scarcely any fashion so changeable and so demanding variation as that of modern cosmetics and perfumes. The last twenty years have seen bewildering progress, and manufacturers have been forced, time and again, to drastic revision of their products and to keen experimentation. Moreover, the future seems to offer no limits to this variety, and their manufacture now demands a deep knowledge and practical experience, for much of it has an empirical basis. The author's previous editions on these subjects are well known in the perfumery and cosmetic world, and have always been accepted as authoritative. The new edition is most comprehensive and, like the previous ones, gives a very practical account of the production, manufacture and application of perfumes and cosmetics. On account of the inclusion of much new matter, the author has made the wise decision to divide the work into two volumes, one dealing with perfumery (vol. 2) and the other with cosmetics and soaps (vol. 3).

Revision has been thorough, and much new matter has been included. Probably the most interesting revision is the section dealing with otto of roses which, although one of the oldest of perfumes, has from its beginning presented a most difficult problem to the would-be buyer. In spite of the great developments in our knowledge of the essential oils, and the application of this knowledge to their evaluation, the chemist has undoubtedly failed in his attempts to detect sophistication, except in very crude form, in this perfume, or to devise constants for its purity. The problem is most controversial, and the author's contribution is of exceptional value as it is a result of a personal visit to Bulgaria, where he was afforded every opportunity for investigation and where he personally conducted the distillation of a large batch of otto. He states that variation in genuine otto must be expected because of the varied methods of production and the varied types of flowers used, and concludes that, after full consideration, the only reliable method of evaluation of the oil must be an olfactic one. He moreover claims that this is also the opinion of the leading perfumery houses on the Continent. Such a conclusion contains little comfort to the would-be buyer, for the olfactic test, of which full details are given, appears to demand exceptional experience. It is, however, this type of information which makes the book so valuable to those whose business it is to handle the products.

The matter dealing with cosmetics (now included in vol. 3) has also been thoroughly revised, and in many instances rewritten. New chapters are given on such modern developments as sunburn preparations, the use of sulphonated alcohols in shampoos, and eye cosmetics. Exact details of preparation have been given, and the difficulties discussed in a manner which reflects the wide practical experience of the author. The work has been well done.

(2) The extensive use of both artificial and natural flavours and essences in confectionery, foods, soft drinks, ice cream, etc., has increased their value and made a study of their production and properties of great importance to the manufacturer.

Unfortunately, in the average book dealing with this subject, it is generally a matter of great difficulty to interpret the meaning of the ingredients specified in the 'recipe', as standards of strength and purity are often omitted. Thus a specified quantity of essence of vanilla is meaningless unless the strength and method of preparation and quality of the vanilla are laid down. The book under review, however, is not open to this objection, for it is devised on the lines of a pharmacopœia wherein all basic materials are of a standard quality, none of them of a proprietary nature, and the strength and method of each preparation are carefully defined. Workers should experience no difficulty in compounding.

An appendix gives simple methods for ascertaining physical constants to control the purity of all ingredients, and simple monographs on the various synthetic flavouring materials such as amyl acetate, phenylethyl acetate, etc. Some three hundred formulæ are given, all of which are woven into a scheme whereby a series of relatively simple basic preparations are first prepared, and then used for the more complicated preparations such as liqueurs and cordials. The author claims that all the preparations are stable during storage for several years. The methods of preparation are very simple, and distillation is rarely required.

A book of this type has long been needed by manufacturers concerned with these products.

H. BERRY.

Comparative Morphology of Plants

Vergleichende Morphologie der höheren Pflanzen Von Prof. Dr. Wilhelm Troll. Band 1: Vegetationsorgane. Lieferung 1. Pp. vii+172. (Berlin: Gebrüder Borntraeger, 1935.) 11.50 gold marks.

THE appearance of a new and, what appears to be, an outstanding work on the comparative morphology of plants is quite refreshing, and may we hope that it will prove to be the herald of a reawakening interest in this most important branch of botanical science.

In his foreword, the author states its scope and object:

> "It differs from other works of this kind in that it resumes once again the tradition of the comparative treatment of form which was lost sight of in the course of the last century, and takes for its guiding principle the idea of the type, that is, the typological unity of the higher plant-kingdom. It is the problem of the archetype [*Urpflanze*] which is here placed in the forefront and centre of morphology."

Morphology has for long been split up into a number of departments which, however useful for affording a knowledge of formative relationships, have missed the inner unifying link. The author's thesis is to restore them to the framework of comparative morphology.

> "Only comparisons founded on the concept of the *type* can demonstrate that the multiplicity of organs or groups of organs is solely conditioned by quantitative differences and divergences around a type as the dominating principle of construction. Morphology thus attains the character of an exact science.
>
> "The slackening of creative output in morphology in the last decades is due, not to the exhaustion of the problems to be solved, but to a failure to see these problems owing to a too intensive investigation of detail and an over-estimation of microscopic analysis which has blurred the vision for the perception of the organism and its organs as a whole."

The real cause of the downward grade of morphology lies in the domination of mechanistic thought over that of "independently-existing life [*Eigenständiges Leben*]". The process of thought from which morphology has degenerated had its origin in the genius of Goethe. Since his day the gradual lapse of morphology into the vogue of considering organic forms entirely from the mechanistic point of view is to-day exemplified by such works as those of Hofmeister and Goebel.

"A true rebirth of morphology is only possible on the assumption that the mechanistic mode of thought is conquered, and replaced by a deeply founded view rooted in a Platonic–Goethian and German mode of envisaging nature", namely, by the recognition of the principle of *unity* of the "*type*", which "type" cannot be analysed or demonstrated, but revealed only to the intuitional eye ; it is derived from an idea, the "*ewig Eine*" of Goethe, manifesting in its multiplicity. More concretely put, "the type must be come at by means of the comparison of organisms in order to discover what is common to them all, this common factor appearing as a *virtual picture* behind the concrete individual forms, and representing the central idea embracing all particular objects". Latter day morphologists, in dealing with the structure of the Ophioglossaceous fertile leaf, to take one example, "instead of basing their study on the typologically true comprehension of the peculiarity, have been content with the external impression of a splitting of the leaf, elevating that into the principle of explanation ; such erroneous paths can only be pursued by those morphologists who cannot distinguish between typological and external resemblance".

Under the heading "Morphology and Development", the author states that there has been a one-sided estimation of developmental history, due to lack of typological insight, and cites as instances of this Grégoire's view of the carpel, A. Foster on the nature of the bud-scale, and Goebel's view of the sympodial inflorescence of Boraginaceæ. Goebel never recognized the typological method, against which he always remained prejudiced. Under "Organography", the author analyses and acutely criticizes Goebel's method and objective, allowing that there are hints at the comparative method here and there in his work, "but that throughout it there exists the attempt to derive the particular form of organs, not from the type, but from the function-principle or the life conditions".

So much for the introductory section.

In Chapter i, entitled "Form-Relationships of the Higher Plants as Portrayed by Particular Examples", Prof. Troll comes to the main task of the work. After stating that "the fundamental thesis running through the whole of morphology is the problem of the archetype [*Urpflanze*]" (Goethe's original idea) and that it "would be a great mistake to connect this problem with propositions of descent-theories", the archetype in the phylogenetic sense being unknown, he begins the descriptive work dealing with the vegetative organs. "Seed Structure and Embryo", "Comparative Analysis of the Fruits of the Horse- and Sweet Chestnut", "Monopodial and Sympodial Branching", "The Bulb of the Snowdrop", "Turnip-rooted Plants and Geophytes", are a few of the headings which will give an idea of the subject-matter of this section of the book. The descriptions are original and perspicuous, and every subject is illustrated by admirable diagrams, drawings or photographs.

We heartily endorse the views of the author as set forth in the introductory section, being convinced that the position he assumes is the correct one for facing the problems of comparative morphology. Others, however, may not so readily accept this position. As regards the main, descriptive portion of this first part of the first volume, we feel sure that it will be of indispensable utility to the student of morphology. Moreover, we venture to prophesy that, when completed, this book will be, to judge by its first instalment, one of the best treatises of plant morphology extant.

W. C. WORSDELL.

The Science of Highway Engineering

Road Aggregates:
Their Uses and Testing. By Dr. Bernard H. Knight. (The Roadmakers' Library, Vol 3.) Pp. x+264. (London : Edward Arnold and Co., 1935.) 21*s*. net.

UNDER the pressure of modern conditions, the art of road-making has of necessity become the science of highway engineering, in the process beginning to borrow freely from those older branches of applied science—chemistry, physics, geology and engineering.

The literature which is rapidly growing up to serve the new purpose expresses the need of freedom from restraint and the necessity of treating certain sections of this field from the basic and more scientific aspect. The process can indeed be reciprocal, as when there is produced from actual practice some new matter to add to the sum of knowledge in the parent science.

The present volume is an excellent example of these principles. The petrology of rocks has been exhaustively studied in the past, and those general principles are here given a special emphasis by an author who has established a position of authority on the structure of rocks with special regard to road stone and aggregates, which forms one of the most important industrial applications of that knowledge.

Road-making to-day consists as to 99 per cent of various processes for the combination of road aggregates with a binding agent into a homogeneous structure. The binding agent and therefore the product respond to certain physical laws, but the value of the aggregate has to be appraised in terms of size, shape, toughness, proportions, texture and ability to amalgamate with binder, etc.

A fuller appreciation of these important and related factors is becoming increasingly more widely recognized, and the present volume is a most timely addition to the literature at a period when road policy and expenditure has attained a breadth and sweep never before exceeded. The subject has been carefully prepared, both in scope and treatment, by one who plainly embodies his own knowledge and practice, and the discussion and orderly presentation of the material at his disposal will make the volume of special use and acceptability to highway engineers.

The author has clearly set out a technique for the estimation and measurement of quality in these materials required to form the rock framework of modern road structures, whether assembled as concrete, asphalt, tarmacadam or just stone, and the structural considerations of rocks and the tests of their properties is well emphasized.

The work therefore merits the highest praise, that is to say, it will be of real service and guidance to all engineers responsible for expenditure on those works which have to be created to sustain the stress of modern road traffic.

R. G. H. CLEMENTS.

Heat for Advanced Students

By the late Edwin Edser. Revised edition by N. M. Bligh. Pp. x+487. (London: Macmillan and Co., Ltd., 1936.) 6*s*.

EDSER'S "Heat for Advanced Students" has been familiar to successive student generations in schools and colleges since it was first published in 1899. The essential character of the book is retained in this revised edition, prepared by Mr. N. M. Bligh after the death of Mr. Edwin Edser in 1932. The methods of the calculus have now been introduced, resulting in more concise treatment, and the term calorie, in conformity with present usage, replaces the therm previously used in the same sense. Recent developments of the subject have been described, and the chapter on radiation has been rewritten so that it now includes a simple introduction to the quantum theory. In its revised form, the book should make a fresh appeal to teachers and students.

Sacrifice to Attis:

a Study of Sex and Civilisation. By Dr. William A. Brend. Pp. v+350. (London: William Heinemann, Ltd., 1936.) 10*s*. 6*d*. net.

THE author directs attention to the menace of the falling birth-rate in Britain, and laments it. He refers to an article of his written in 1915 in which he says that "we may eventually see the Slav races increased relatively in such enormous proportion that they may come to dominate all Europe". Obviously the race of armament is of no matter; we must start a fierce race to have the highest birth-rate in Europe and so swamp the Slavs by sheer numbers! The author would include many of the psychoses and epilepsy as explainable on the grounds of repression and other psycho-analytic mechanisms. We would be interested to hear the results of treatment of these conditions on psycho-analytic lines. We have seen little good result in these psychoses. It is easy to advance theories but so difficult to convince scientifically minded people.

Essential Traits of Mental Life

By Truman L. Kelley. (Harvard Studies in Education, Vol. 26.) Pp. viii+145. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1935.) 11*s*. 6*d*. net.

PROF. KELLEY gives as the sub-title of the little book under notice, "the Purposes and Principles underlying the Selection and the Measurement of Independent Mental Factors, together with Computational Tables". He presents a new method of factorization which certainly appears simpler than that of Hotelling's method of analysis. He compares the work of Brown and Stephenson, of Tyner, of Godfrey Thomson, with Spearman. We cannot agree with the statement that "the line of argument . . . is so simple that the meaning of what is accomplished should be clear to the student familiar with the most elementary mathematics". The mathematics involved are by no means elementary. The author provides us with an analysis of the vocational groups in the United States.

An Elementary Survey of Modern Physics

By Prof. G. F. Hull. Pp. xxiv+457. (New York: The Macmillan Co., 1936.) 20*s*. net.

PROF. HULL has written a most interesting volume giving an account of modern physics suitable for an American college student in his second year. He has been successful in providing a book of an elementary character which may be recommended to other readers wishing for an up-to-date account of recent marvellous developments. It is not a 'popular' book in the sense that mathematical operations have been avoided altogether, but the mathematical difficulties have been reduced to a minimum. The properties of atoms, electrons and photons, and the relations between them are described in a stimulating way. Such subjects as cosmic rays and transmutation of the elements, and even such abstruse questions as the Schrodinger equation and the uncertainty principle are dealt with.

Progress in the Technique of Crystal Analysis*

By Sir William Bragg, K.B.E., O.M., F.R.S.

THREE years ago, Sir Gowland Hopkins in his presidential address spoke with admiration of the work of the organic chemist and in particular of the "emergence of power to grasp the architecture of complex invisible entities such as organic molecules and the ability to construct them at will". He told how under modern methods of investigation the picture which the chemist had formed of the invisible molecule had actually taken shape. His picture-making had been amply justified. His stereometry was not, as some thinkers had maintained, to be swept away in favour of a mathematical symbolism.

This anticipation has been fully realized during the last few years, mainly through the remarkable increase in the accuracy with which the structure of molecules, molecular aggregates and solid bodies in general can be determined. For this the methods of X-ray analysis of crystalline structure have been largely responsible. Moreover, other methods have been greatly strengthened by the example set by X-ray analysis and by its reactions upon themselves. Optical, electrical, magnetic and other properties have been successfully studied with the same great purpose, namely, the correlation between the properties of a substance and the spatial arrangements of its components.

While the X-ray methods have been mainly useful in describing the arrangement of the atoms in assemblages surrounded by others of like nature and conditions, the methods of electron-diffraction are giving a remarkable insight into the modifications of arrangement that are to be found on surfaces. The extraordinary interest of such knowledge arises from the fact that natural processes so largely depend on surface actions.

For many years after its inception, the X-ray analysis was, as might be expected, engaged in trying its own powers and learning how to apply them. It cleared up many structural problems on which older methods had little to say that was definite, as for example the distinction between ionic, metallic, adamantine, and molecular compounds. Many crystalline structures were determined, and the results, as is well known, have been serviceable in a wide field of scientific research, and in many industrial processes. The methods of analysis, the technique and the interpretation of results have been greatly improved, as might be expected, by the researches of many hundreds of workers. The increase in accuracy is so great that new possibilities of usefulness come into view.

The improvement appears in two ways. In the first of the two, the measurements of the dimensions of the unit of pattern of a structure can now be made to one part in several thousand. Consequently, the determination of the electron charge *e*, made by the X-ray method, can stand beside the older determinations of the oil-drop method. There is a persistent discrepancy of about one part in two hundred, the former giving the value $4{\cdot}80 \times 10^{-10}$, the latter $4{\cdot}77 \times 10^{-10}$; but it is clear that the larger value is at least as near the true value as the smaller. A full discussion of the X-ray method is given by Compton and Allison in their recent book on "X-rays in Theory and Experiment", and a critical examination of some outstanding points is made by du Mond and Bollman (*Phys. Rev.*, Sept. 1936).

Again, as has been observed by Bernal, the use of high-precision determinations of the lattice constants of metals will soon become the most reliable gauge of purity of a metallic element. Accuracy has here been pushed to one or two parts in forty thousand. The phase boundaries of an alloy also can be very closely and conveniently defined by observations of such a character. Accuracy has been of great importance to the well-known work of Hume-Rothery on alloy structures, and to the curious and very important relations between order and disorder in alloys which have been specially studied at Manchester.

The accuracy with which the position of each atom in the unit cell can be measured is of quite a different order. Thanks in particular to the use of Fourier analyses by J. M. Robertson and others, the distances separating the atoms, centre to centre, can be found to about 1 per cent, even when the complicated molecules of organic crystals are under examination. This is a great advance on the possibilities of even a few years ago, and it has important consequences. In particular, fresh light is thrown upon the problem of the chemical bond. At one time, single, double, and triple bonds were considered to be distinct and definite phenomena. The tetravalency of carbon, for example, was described as an assemblage of four equal powers of combination, of which one or more might be exercised in the same direction. When the diamond structure was found by the X-ray methods, it was no matter of surprise that the four separate single bonds were displayed in the attachment of each carbon to four neighbours. In the structure assigned by the chemist to benzene, the fact that each atom had but three neighbours presented difficulties; various theories have been suggested in explanation, mostly little more than different ways of drawing diagrams, in which four single bonds were made to act somehow. In recent years, it has been more usual to propose that bonds may alternate between single and double, and that the tetravalency of carbon in the benzene ring is satisfied because three of the six links are double and three single, the two kinds alternating both in time and in order round the ring. The conception can be extended to cases much more complicated provided that the two forms between which alternation occurs do not differ much either in form or energy. The effect is described as one of 'resonance', a term due to Hund but applied to organic chemistry mainly by Pauling and his collaborators. Its bearing on structural chemistry was discussed by Sidgwick a few months ago in a presidential address to the Chemical Society.

---

* From the presidential address to the Royal Society, delivered on November 30.

When substances in which this 'resonance' is supposed to occur are examined by the X-rays, it is found that the actual centre to centre distance of two atoms connected by a link alternating between single and double is characteristic of neither of the two extremes. These last two are definite quantities, and the length of the varying link lies between them. An actual link is rarely a pure single or double or triple link. Pauling and Sidgwick both discuss a number of cases in which the centre to centre distances can be correlated with a probable or possible amount of resonance. An excellent example is furnished by oxalic acid, which was examined by Zachariasen in 1934, but has just been remeasured by Robertson, using the powerful Fourier method of analysing the observations. The distance between the carbon atoms is 1·43 A. The length of the single link of diamond is 1·54 A. The length of a double bond is very nearly 1·33 A. It might seem that in oxalic acid the link is actually more nearly double than single; but this is not so A small proportion of double linking seems to shorten the distance considerably. For example, each link in the hexagonal network of graphite must be two-thirds single and one-third double, yet its length is 1·41 A. In benzene, the half and half arrangement (following Kekulé) is correlated with a length of 1·39 A. or 1·40 A. Thus the actual length of a bond may prove to be a safe indication of its nature. Robertson points out that the oxalic acid molecule is always planar, which may be accounted for on the ground that rotation is restricted round a link which is even partially of a double character.

It has recently been shown by Bernal and Megaw (*Proc. Roy. Soc.*, A, 151, 384; 1935) that in all probability there are two types of bond linking oxygen atoms through intermediary hydrogens. One is the 'hydrogen bond'; it is found, for example, in acids, and it corresponds to a separation distance, oxygen to oxygen, of 2·55 A. The other is the hydroxyl bond; it is found in a number of hydroxides, and its length is about 2·8 A. By the use of this conception it has been found possible to locate the positions of the hydrogen atoms in several hydroxide structures, particularly in the clayey mineral hydrargillite. The oxalic structure of Robertson seems to supply a new and interesting example of the difference between the two kinds of bond. One of the oxygens at each end of the oxalic acid molecule is bound to a water molecule in the crystal by a link 2·87 A., the other by a link 2·52 A.

It has been pointed out (Fricke, *Koll. Z.*, 69, 312; 1934) that the linking up of hydroxyl bonds explains the properties of the gels that are formed by neutral hydroxides.

These few examples may serve to show how improvements in the technique of X-ray analysis are sharpening a tool which has already been of assistance to research in many directions and now seems to be acquiring a new usefulness.

The chemist has already shown that the properties of the molecule depend on the internal disposition of its atoms. The characteristics of the solid state depend also on spatial relations, and in a manner which is even more complicated, much more complicated than in the case of the independent molecule. Accurate measurement of the spatial arrangements lays a firm foundation for the study of the properties of a substance in relation to its structure and its composition. The problems to be solved are, of course, extremely complex, but it is surprising how much can be done towards the examination of intricate molecular associations when the spatial relations between the most commonly occurring atoms are known. This applies, for example, to the study of the proteins, which has already gone far; to the clays, and to the glasses and other extended structures. At one time it seemed hopeless to expect to learn much of the structure of bodies which were so irregular as to give no sign of crystallinity. But it is now possible to work from the regularity in occurrence of a few definite separation distances, even when regularity in orientation does not exist: and methods have been devised by which these distances can be determined by the X-ray methods.

It is clear that the stereometry which the chemist has developed so successfully is acquiring new powers which will have the widest applications.

Nature and Control of Potato Virus Diseases

By Prof. Paul A. Murphy

THE discussion on September 15 in Section M (Agriculture) of the British Association on "Scientific Aspects of Potato Growing" proved useful and timely. Inevitably the discussion was entirely pathological, ranging from virus diseases to potato sickness caused by the eelworm, *Heterodera Schachtii*, which may reduce the value of potato land from £2 to 10*s*. per acre. Most of it, however, concerned virus diseases and the raising of healthy seed potatoes. The magnitude of the question is shown by the fact that there are half a million acres of potatoes in England and Wales, and of these some 120,000 acres are planted with Scottish or Irish seed potatoes annually. The balance is planted with local seed, and it is a question to what extent this could be profitably replaced, for fresh seed is estimated to increase yields by one ton per acre. Much also could be done, as has been shown by Bryan at Ormskirk, to maintain the health of the imported seed so as to make it last longer.

The best way to improve the potato crop as a whole, however, is to increase the vigour of the imported seed stocks. It should now be possible to guarantee the entire absence of leaf roll, which is the principal cause of degeneration. This disease depends on the aphis, *Myzus persicæ*, for its spread, and Davies has shown that its prevalence depends on such simple physical factors as temperature, humidity, wind, and system of cropping. It hibernates on Brassicas and migrates to potatoes from May on, whenever the temperature rises above 55° F. (optimum 70°–80° F.); the humidity is 70 per cent or less, and the wind does not exceed 5–6 m.p.h. This knowledge enables one to avoid the indifferent districts, but not to turn them into good ones. It also explains why the best seed is to be found in exposed, wet and windy places, particularly near the sea, where farming is mainly pastoral and potato fields isolated. The connexion of good seed with islands is proverbial.

The potato mosaic question has been in danger of becoming a mystery, but the time has come at last when a clarification is possible. Some of the difficulties have been artificial ones. In the laboratory a single virus can be made to produce mottling, streaking, or no symptoms, by choice of the proper variety, but the general rule in Nature is that the virus is either carried or expresses itself as a mottle only. In other words, those varieties in which a virus causes streak, as virus X does in Arran Crest or virus A in British Queen, are free from that infection, for the virus either kills the plant and tubers, or kills itself while localized in the necrotic spots. Virus Y, which is the usual cause of streak, is sometimes an exception, but the general rule holds good: one virus, one disease. This is an enormous simplification.

It is probable that no virus is entirely harmless, although in some cases no natural spread or effect on yield has been demonstrated. Omitting such, it is found that the principal potato mosaics are caused by the four viruses X, F, Y and A, alone or in combination, and these form the types of three natural groups, viruses Y and A, though distinct, being at present placed together on account of the occurrence of intermediate forms. These groups are very shortly characterized as follows:

Group 1. X-type viruses. Mottle on *Datura* and tobacco; pass $L3$ filter; vector unknown (not *Myzus persicæ*); typical disease, simple mosaic.

Group 2. F-type viruses. Spots on *Solanum nodiflorum* and *Capsicum annuum*; carried by tobacco and *Datura*; held by $L3$ filter; vector, *Myzus persicæ* under certain conditions; typical disease, yellow or aucuba mosaic.

Group 3. Y-type viruses (including virus A and vein-banding virus). Vein-banding on tobacco; not inoculable to *Datura*; held by $L3$ filter; vector, *Myzus persicæ*; typical disease, veinal mosaic or leaf-drop streak.

The four viruses mentioned, together with their four combinations, produce eight diseases as follows, though complexes of more than two terms also occur:

1. $X =$ simple mosaic.
2. $F =$ yellow mosaic
3. $A =$ veinal mosaic.
4. $Y = \left\{\begin{array}{l}\text{veinal mosaic.}\\ \text{leaf-drop streak.}\end{array}\right.$
5. $X + F =$ interveinal mosaic.
6. $X + A =$ crinkle.
7. $X + Y = \left\{\begin{array}{l}\text{rugose mosaic.}\\ \text{leaf-drop streak.}\end{array}\right.$
8. $A + F =$ double virus aucuba

The first three diseases are normally passed over in the field, the eighth is not very common, and the remainder make up the mosaic of the practical man. These, as will be seen, are caused by a virus transmitted by *Myzus persicæ*, either alone or in combination with X. This, therefore, reduces the mosaic problem to two dimensions: the control of *Myzus persicæ*, which is only the leaf roll problem over again with the additional complication of carriers, and the control of virus X. The latter is still an enigma, for though it spreads so freely as to be almost ubiquitous, occurring for example throughout the variety Up-to-Date, and in all American commercial potatoes without exception, its vector is unknown. It infiltrates rapidly into virus-free stocks even when grown in isolation in the best districts, and is not entirely unknown in experimental glasshouses. As part of the basis of all the severe mosaics it is an active danger, but the question still awaits answer whether it is economically possible or necessary to control it as well as the aphis-borne viruses.

The viruses mentioned are not uniformly distributed throughout Great Britain and Ireland. In the best districts, leaf roll is absent, *Y* is rare, *A* is more common and *X* is nearly universal, while in the south-east leaf roll and virus *Y* become comparatively common. The useful life of a variety depends on its reaction to the local viruses, and the moderate reactors suffer most and last shortest, a good example being Arran Chief. The carriers and strong reactors escape best. Outstanding varieties, such as the famous Up-to-Date and British Queen, are intolerant of *A* and probably resist infection with it as well. Up-to-Date tolerates *X* and British Queen resists it. It appears to be the reaction to these two viruses which determines the survival of a variety in Great Britain. If it tolerates *Y* as well so much the better, but our best potatoes lack this quality, a fact which explains the failure of Up-to-Date in the interior of the United States and Canada, as probably also in Central Europe. The control of virus *Y* at home depends on the use of Scottish and Irish seed potatoes.

Dental Caries and Diet

IN spite of the facts that there are more dental clinics, that many more people brush their teeth and that more dental treatment is practised to-day than ever in the world before, dental disease seems to be as prevalent as it has ever been, especially among civilized peoples. The experimental work of Mrs. Mellanby has shown that there is an intimate relationship between the diet and the structure of the teeth in both animals and man, and that there is similarly a close relationship between structure and liability to caries in man. It remained to be proved that the incidence and progress of the disease could be influenced by alterations or additions to the diet.

The results obtained in the first stages of the investigations carried out with this object have already been referred to in these columns (NATURE, 129, 83; 1932: 133, 820; 1934). The final report* of the Committee for the Investigation of Dental Disease describes the influence of diet upon caries in children's teeth and shows that the teeth, like other organs of the body, are strongly influenced by nutritional factors brought to bear upon them, whether through their blood supply or the saliva. The dental decay that developed in the children receiving an addition of vitamin D to their diet was definitely less than in the control children not receiving extra vitamin, and its influence in inhibiting the initiation and spread of caries was especially impressive when the addition was made during the period of development and before full eruption of the teeth.

The investigations were made in three similar institutions in the neighbourhood of Birmingham, maintained on the Cottage Home System, under the Poor Law authority and later under the local education authority. It was at first hoped to divide the children in each institution into three groups, each receiving a different supplement, so as to avoid the possible influence of slightly differing conditions in the homes affecting the results, but administrative difficulties prevented this and all the children in one home were given the same addition. Analysis of the basal diets showed that they were fairly similar in the three institutions: the variations, described in the report, probably did not affect the general conclusions drawn from the results obtained. Three experiments were carried out. In the first, the three institutions had daily additions to the diet of treacle (28–42 gm.), olive oil (14–21 c.c.) and cod liver oil (14–21 c.c.; 50–100 units of vitamin D per c c.) respectively. In the second, carried out in one institution only, one group of children received the olive oil and the other vitamin D in olive oil (625 units per c.c.: 14–21 c.c.). In the third, the children were younger (2–5 years old) instead of 5–14 years old, and the additions were treacle, vitamin D in olive oil and cod liver oil in daily doses of 7 gm. or 7 c.c., in three different institutions. Although about 1,600 children were under observation for varying lengths of time, the number who received the special additions for the full period of three years was much less.

Six-monthly examinations were made of the mouth and of the general physical condition with

* Medical Research Council. Special Report Series, No. 211: The Influence of Diet on Caries in Children's Teeth (Final Report). By the Committee for the Investigation of Dental Disease (assisted by Alan Deverall and Mabel Reynolds). Pp. ii+137. (London: H.M. Stationery Office, 1936.) 2*s*. net.

special reference to the bones. The surface structure of the teeth, their arrangement in the jaws, the number of carious teeth and the extent of caries in each, as well as the condition of the gums and the general physical state were noted at the beginning of the investigation and at each subsequent examination. The differences between the findings at the first and final inspections in each diet group were then compared.

This investigation has shown again that there is a definite direct association between the structure of the teeth and the amount of caries present in a mouth: this relationship was found in the case of both the original and newly erupted permanent teeth in the olive oil group. Although no definite evidence was obtained that diet had an effect upon the structure of the permanent teeth, there were indications that the addition of vitamin D during the period of development tends to improve the structure of the first permanent molars. On the other hand, it was proved conclusively that a high vitamin D intake before the full eruption of the permanent teeth significantly diminishes the incidence of caries in such teeth after eruption: this protective effect was especially striking in the case of the premolars and second permanent molars, which erupt later than the first permanent molars. As regards the deciduous teeth, only in the case of the youngest children could any effect of the additions to the diet be expected; evidence was obtained that caries was less progressive in the vitamin groups than in that receiving treacle.

It is of interest to note that although the incidence of fresh caries in the permanent teeth present at the beginning of the investigation was the same in the two control groups, yet the spread and degree of softening were significantly greater in the olive oil group: in the case of the deciduous teeth, however, there was a greater increase in the percentage of carious teeth in the treacle than in the olive oil group.

Summing up the results of these extensive experiments, it may be concluded that a relatively high intake of vitamin D can do much to diminish the incidence of caries if the vitamin is given during the period of development of the teeth: that a beneficial effect may be obtained if it is given at a fairly late stage of development; and that even when it is given after the eruption of the teeth, the onset and spread of caries are delayed.

Problems of Plantation Economy

IN choosing the subject of "Plantation Economy" for his presidential address to Section F (Economics and Statistical Science) of the British Association, delivered at Blackpool on September 11, Dr. C. R. Fay rightly directed attention to a neglected corner of knowledge which has lessons of much interest to the sociologist as well as the economist, to the historian, the geographer and the administrator as well as the agriculturist. Dr. Fay was clearly inspired by a recent tour in the East, and dealt mainly with the tea plantations of India. He contented himself with a straightforward account of the industry, and refrained, perhaps wisely, from comment on the wider issues.

The Royal Commission on Labour in India (1931) pointed out the similarity between a plantation and a factory—both employing a considerable number of persons under the control of a manager. The chief difference is that the work in one case is essentially agricultural and is not concentrated in a large building. The analogy is important; until regulated by factory acts, 'exploitation' of labour too often characterized the growing manufacturing industry just as exploitation of labour—including slavery—characterized the early plantation industry. Tobacco in the south-eastern United States, and sugar in the West Indies a hundred or more years ago, ought to be thought of in comparison with the Lancashire cotton mills of the same period. It is scarcely possible to contemplate the modern world without a factory system, yet the corresponding plantation system is not only less important than formerly, but also may be described as 'suspect'. To-day, India, Further India and the East Indies are the home of the greatest plantation industries, tea and rubber, and this is considered by Dr. Fay to be due in considerable measure to Government opposition to the system in Africa. Dr. Fay quotes figures in his opening paragraph to show that, despite a relatively small area, plantation products (mainly tea) account for nearly a fifth by value of the agricultural exports of India. This statement has little meaning—what one would like to know is the relative productivity of a given area of land under plantation organization and under unregulated native cultivation, and the relative cost per unit of production, having due regard to quality.

Since the bulk of the world's tea is produced in plantations, it will be of interest to detect the reasons for the persistence of plantation economy in the case of this commodity. In the first place, tea is in large demand among the white races, yet is the product of a tropical or sub-tropical shrub growing under conditions unsuited to white manual labour. Here is the essential basis for the old plantation industry in sugar, cotton, tobacco and indigo, and the modern industry in rubber. In the second place, rigid adherence to a daily time-table is essential—tea leaves must be plucked exactly when they are ready; the 'flush' must be dealt with immediately at the factory, withering must go on until almost exactly 42 per cent of the moisture is lost—after about eighteen hours. This all means adequate organization and supervision, or the quality of the resulting tea will suffer. There would be no market for the output of a factory which did not maintain an even standard. So much so is this the case that most factories consider it unwise to use supplies from other than their own plantations. Herein lies an important difference from other plantation industries—cotton can be bought according to quality from the small-holder; sugar cane can be brought to the sugar 'central' and does not deteriorate so rapidly. With tea the deterioration after plucking is so marked that 'lorry tea' (that is, brought in by the quickest method of transport) is regarded as superior.

Dr. Fay points out that, in the early European settlement of the New World, 'plantation' and 'colony' were virtually synonymous; the plantation was the economic instrument whereby colonies were established. Conditions of life were difficult for employee and manager alike. To be sent to the plantations was equivalent to disciplinary banishment for the turbulent younger sons. The negro States and the West Indies owe their population—and many of their present-day problems—to the system. It is curious that the present home of the plantation—the East—was, with its existing large population, at this earlier date recognized as a field for trade rather than colonization. Thus India and the East Indies had trading posts and forts to guard them, but not plantations. Since tea and rubber planting began there much later, its history has been happier. The tea-gardens of Assam attracted to that pleasant province labourers from overcrowded Bihar who, after their term of work was finished, settled down to work the land under conditions far superior to those in their home areas. Four fifths of the people of Assam are 'foreigners' by birth or origin—the tea-gardens have enabled this important migration to take place and have done much to relieve one of the pressing population problems of India. To a less degree the rubber plantations of Malaya have had the same effect, with the difference that the Indian coolies have not been encouraged to settle. But rubber has given Malaya and the Dutch East Indies fine roads and railways and a vastly improved standard of living for the people.

The plantation system, under modern humane supervision, may thus confer great benefits on a world the agriculture of which is in a state of chaos. Not only may it provide diverse parts of the earth with commodities otherwise unobtainable—a good example is the highly organized banana industry—but it may also prove the way to development and settlement of tracts to which the individual settler without capital neither could nor would be attracted. Our economists and sociologists would be doing a great service by studying dispassionately the application of a modern plantation economy in Africa, Australia and other sparsely populated parts of the world.

L. DUDLEY STAMP.

The Hexlet*

HOWEVER ill-assorted in girth three spheres may be
Each one can kiss the other two and simultaneously
A ring of six about them all kissing serially.

Though any necklet of graded beads
May fit in general the she-sex,
This Hexlet of mine of novel design
Caresses not one but three necks.
However it's worn it alters its grade
To suit its tri-spherical prison,
Plays kiss-in-the-ring and merry-go-round
Whilst hugging three necks with precision.
Like bubbles that blow and dwindle and go
It holds up to light-hearted derision
The terrible muddle mathematical fuddle
Makes of the pure circumflex
And its pet aversion is the mental inversion
That will have 'It's $1/x$'.

All saints and sages throughout the ages
From one doxy never have swerved,
To hold fast unto what in change changes not
And ferret out what is conserved.
Now these beads without flaw obey this first law
For the aggregate sum of their bends.
As each in the tunnel slims through the funnel
Its *vis-à-vis* grossly distends.
But the mean of the bends of each opposite pair
Is the sum of the three of the thoroughfare.

FREDERICK SODDY.

Obituary

Prof. W. J. Sollas, F.R.S.

IN the death on October 26, at the age of eighty-seven years, of William Johnson Sollas, the University of Oxford and the science of geology have lost an outstanding personality. To a liberal culture, especially on the scientific side, he added a wide and ever-increasing knowledge of his own subject, a genius for research which extended to all its chief branches, and a philosophical point of view which always penetrated to the deeper and more theoretical bearing of the subjects with which he dealt.

Born at Birmingham in 1849, Sollas was educated at the City of London School, where chemistry was the chief subject of his interest, and at the College of Chemistry in Oxford Street, London, where he worked in Frankland's laboratory. He passed with a scholarship to the Royal School of Mines, obtained the A.R.S.M., and finally, with two of his brilliant contemporaries, Liversidge and Garnett, obtained a scholarship at Cambridge, he and Garnett being admitted to St. John's College. Here T. G. Bonney was not only his tutor, but was also acting as deputy professor of geology in Sedgwick's declining days. His influence turned Sollas towards geology as his principal subject, and he graduated with first class honours in the Natural Sciences Tripos in 1873. He was a fellow of his college in 1882–84.

Sollas's first appointment was on the University Extension, where his lectures were most successful and bore traces of the influence of Huxley and Tyndall in their clarity and attractiveness, and of Ramsay in their imagination and enthusiasm. In 1879 he was appointed professor of geology and zoology at University College, Bristol, a post he held until 1883, when he passed to Trinity College, Dublin, as professor of geology and mineralogy. Finally, in 1897, he became professor of geology and palæontology at Oxford, a chair he occupied until the end of his life, thirty-nine years, having been also elected a fellow of University College in 1901.

The anomalous "Cambridge Greensand", which inspired the early work of so many students of the Cambridge school, had its influence on Sollas, in the direction taken by his work on fossil sponges, on which he published more than thirty papers before 1890. This stage culminated in a new classification of the Spongida, articles in Cassel's "Natural History" and the "Encyclopædia Britannica", and a monograph on the Tetractinellidæ collected by H.M.S. *Challenger*. In his work he was interested not only in the systematic and anatomical results, but also in the physical principles involved in the development of the skeleton, and in the chemical interchanges of silica and carbonate of lime in their formation. The latter led him directly to study the origin of flint and chert, on which he evolved a theory that has stood the test of time. To help his work on minute organisms he devised a new use for heavy liquids, arranging them in a 'diffusion column', in which the specific gravity of such bodies could be determined by the depth to which they sank. This method he later applied to minerals and rocks, and to such fluids as blood.

Sollas's palæontological work was extended to brachiopods, echinoderms, Foraminifera, and to *Oldhamia* and its allies; he also described a new species of *Plesiosaurus* and worked out the geographical range of this genus. But perhaps his most outstanding work on organisms other than sponges was his application of the method of serial sections to the study of fossils. The ordinary zoological method was impracticable because of the intervals lost in grinding down successive slices. Sollas, therefore, worked out a mechanism and technique for grinding down specimens by stages, and, at intervals of a fraction of a millimetre, photographing and drawing in reflected light the surfaces thus obtained. Models of each section in gelatine or other medium could then be made and the organism built up at any desired magnification on successive contours, yielding a restoration of all the detail that it had preserved. A remarkable early success was obtained with *Monograptus*, and this was followed by work on a Silurian brittle-star, a Devonian fish, the skull of *Ichthyosaurus*, and, with the co-operation of his daughter Miss Igerna Sollas, a dicynodont skull. It may fairly be said that nothing has done more to advance knowledge as to the intimate anatomy, and even physiology, of extinct animals than this technique in the hands of its inventor and his successors.

When he had rounded off his sponge work, Sollas turned eagerly to petrology, and his researches on the Wicklow granite and the Carlingford complex were the most elaborate investigations undertaken up to their date. In one case he saw that the pleochroic haloes must be attributed to a new element, since identified by Joly as radium, and in the other he did much on the mixture, hybridism and metamorphism of rocks. Acting for a few years as petrographer to the Geological Survey of Ireland, he put out other work on rocks, and also assembled the evidence collected by the Survey for the issue of a map of the glacial esker system of the country. Work upon minerals was confined to a couple of papers on zinnwaldite and riebeckite, but he made a strenuous endeavour to discover the molecular structure of crystals, a subject which had awakened his interest when he first learnt at the School of Mines of Haüy's contributions to crystallography, and when Garnett advised him to test his early speculations by the atomic volumes. The data at his disposal were inadequate to carry him so far as X-ray investigation has taken Laue and the Braggs and their successors, but a series of papers published by the Royal Society indicates that he was on the right track.

The chief researches conducted by Sollas in later years were concerned with early man. He definitely assigned the Gibraltar skull to Neanderthal man, explored the Paviland Cave with its relics of Cro-Magnon man, dealt with *Pithecanthropus* and *Eoanthropus*, and applied the use of sagittal sections of the skull to a critical study of most of the Palæolithic skulls that have attracted recent attention.

Wide as is the range of work thus briefly outlined, Sollas's many activities included others of which only the barest mention is possible. Such are his application of the idea of evolution in place of uniformitarianism to geological history, his study of the geology of Bristol, Dublin, Oxford, and the Silurian Inlier of Rhymney near Cardiff, his ingenious method of studying tidal movements and their effect on the estuarine sediments of the Severn, his philosophical explanation of the origin of freshwater faunas, his study of a bog-flow in Kerry, his attempt to bore through a coral reef in the Ellice Islands, afterwards carried to success by Edgeworth David and his colleagues, his addresses and books on the age of the earth and on ancient hunters in comparison with those of to-day, and the fostering care with which he watched the translation by Miss Hertha Sollas of Suess's great work "Das Antlitz der Erde", a remarkable service to British geology for which we are deeply indebted to both father and daughter.

Sollas was awarded the Bigsby Medal and the Wollaston Medal by the Geological Society, of which he became president in 1908, a Royal Medal by the Royal Society, and the Huxley Medal by the Royal Anthropological Institute. He was made an honorary fellow of the Imperial College, and received honorary doctorates from the Universities of Bristol, Dublin, Christiania and Adelaide. His death leaves, with his associates, pupils and successors, the memory of a lovable and constant friend, a gallant and doughty foe, a sprightly debater and formidable controversialist, a daring climber and diver, an omnivorous reader, a writer of clarity, vigour and humour, an investigator of untiring energy and unimpeachable accuracy, and, whether as host or guest, a genial and most courteous gentleman.

W. W. WATTS.

An anthropological correspondent writes as follows :

Although Sollas entered upon active study of the problems of early man late in life, he rapidly became an outstanding authority. His training and experience as geologist and palæontologist inspired confidence in his balanced judgment in the discussion of chronological and morphological problems relating to early man; while his originality and constructively critical attitude of mind, which refused to be dominated by traditional methods or accepted opinion, found ample opportunity for exercise in his studies of the various types of fossil man, in which his development of the method of craniological investigation by sagittal sections showed a remarkable grasp of the morphological and metrical problems involved in comparative study.

One of Sollas's earliest archæological investigations to attract widespread interest was his exploration of the Aurignacian site in the Paviland cave of the Peninsula of Gower, South Wales, in which a prehistoric skeleton, known as the "Lady of Paviland", was found. Here Sollas discovered painting in red on the wall, which, notwithstanding counter-argument —to be anticipated in the circumstances—that it was the recent work of a fisherman, remains the only example of cave-painting in Great Britain for which the claim of palæolithic age makes any showing.

Sollas published in scientific periodicals a number of papers on early man, which are of permanent value; but his most considerable contribution to the literature of the subject is—and will continue to be notwithstanding later discovery and development in method and classification—his "Ancient Hunters" (third edition, 1924). Sollas had been much impressed by the Bushman tribes he had seen in the Kalahari, when the British Association visited South Africa in 1905. The influence of that experience is to be seen in the degree to which he made use of the cultural complexes of modern hunting peoples in the interpretation of the archæological evidence bearing upon the cultures of the hunting peoples of the Old Stone Age. As a general principle the method was not new to archæology, but Sollas gave it scientific precision. His references to Bushman art and associated custom and belief in certain respects anticipated later studies and discovery; while in his comparisons of Magdalenian culture with that of the Eskimo he directed attention once more to matters from which interest had been diverted. It was in this connexion that he entered into one of the most strenuous controversies of his later life when he produced his study of the late Palæolithic Chancelade skull and affirmed its affinities to that of the modern Eskimo.

We regret to announce the following deaths :

Prof. J. T. Cash, F.R.S., emeritus regius professor of materia medica in the University of Aberdeen, on November 30, aged eighty-two years.

Sir Edwin Deller, principal of the University of London since 1929, as the result of an accident, on November 30, aged fifty-three years.

Prof. E. H. Kettle, F.R.S., professor of pathology, British Postgraduate Medical School, University of London, and consulting pathologist to St. Bartholomew's Hospital, on December 1, aged fifty-four years.

Mr. W. H. Macaulay, fellow of King's College, Cambridge, author of "The Laws of Thermodynamics" and "Solid Geometry", on November 28, aged eighty-three years.

Lady Ramsay, widow of Sir William Ramsay and affectionately associated with many friends at University College, London, and other scientific circles, on November 26, aged eighty-two years.

Prof. Wilhelm Schmidt, professor of physiography in the University, and director of the Central Institute for Meteorology, Vienna, on November 27, aged fifty-four years.

Dr. Lilian Veley, an original woman fellow of the Linnean Society of London, known for her work in entomology and microscopy, on November 27, aged seventy-five years.

News and Views

An Institute of Chemotherapy

THE malaria epidemic in Ceylon in 1934–35 directed attention anew to the importance of chemotherapy, particularly in relation to malaria, and the subject received full discussion at a joint meeting of Sections B (Chemistry) and E (Geography) of the British Association at the Norwich meeting. Last July, the Royal Society decided upon a scheme for research on malaria, and, as part of it, Lieut.-Colonel J. A. Sinton was appointed for a period of five years to work at the Malariatherapy Centre at Horton, where he would be able to include chemo-therapeutic testing and experimentation in his investigations. Hitherto, little work has been done in Great Britain on this subject, in spite of the fact that the British Empire includes vast malarious areas in Africa, India and the Far East. In the British Association discussion referred to above, Colonel S. P. James stated that of the 3½ million deaths annually from malaria, the great majority occur in the British Empire, and that the Empire spends £450,000 annually on quinine for combating malaria. It is now announced that Great Britain is to have an institute of chemotherapy, and at the annual dinner of the Royal Society, Mr. Neville Chamberlain stated that, as Chancellor of the Exchequer, he had just consented to give a grant of £30,000 a year towards the establishment of such an institute. It is difficult to foresee, he said, all the possibilities of the new institute, but the fact that the grant has been made is evidence that the Government is not indifferent to the duty of one generation to carry on investigations which may benefit only the generations to come.

Royal Society Research Funds

ACCORDING to the annual report for 1936 of the Council of the Royal Society, Mr. H. B. Gordon Warren, who died in 1932, directed that the income of his residuary estate should be used for the promotion of scientific and industrial research, and in particular to advance knowledge in metallurgy, engineering, physics and chemistry. The trustee of the estate, Williams Deacon's Bank, Ltd., has agreed that the trust shall be administered by a committee consisting of two members appointed by the Bank and eight others appointed by the Royal Society. It is understood that the fund will be slightly in excess of £200,000. The Society has also received the residuary estate of the late Sir Joseph Petavel, which amounts to about £40,000. During the past year, the Society applied to H.M. Treasury for an increase of £1,000 annually for the grant-in-aid for scientific investigations, and an increase of £500 annually for international research associations and scientific congresses. These applications have been approved by Parliament, so that the annual grants for 1936–37 for scientific investigations and for international and other congresses will be £7,000 and £2,500 respectively. From the Parliamentary grants-in-aid, a sum of £6,000 has been allotted to scientific investigations, and a sum of £1,775 to scientific publications of institutions other than the Royal Society. The Council has also decided unanimously to propose to the Society that the number of annual elections to fellowships should be increased from seventeen to twenty.

Charles Frederick Chandler, 1836–1925

ON December 6, the centenary occurs of the birth of the distinguished American chemist, Charles Frederick Chandler, who in 1899–1900 served as president of the Society of Chemical Industry. He was brought up in New Bedford, Mass., being the son of a draper. As a schoolboy he contracted with his father to sweep out and open his shop every morning for a dollar a week, in order to buy chemicals and apparatus. From school he passed to Harvard and the Lawrence Scientific School, afterwards studying chemistry under Wöhler at Gottingen. On returning home, he obtained a post as janitor under Prof. Joy at Schenectady, becoming successively instructor first in mineralogy, then in geology and eventually professor of chemistry. It was at Schenectady that he began his lifelong efforts to bring chemistry into daily life and into industry. In 1864, when the School of Mines was organized as part of Columbia College, he was invited to occupy the chair of chemistry, and thus began his great career as a teacher in New York. He was a founder and sometime president of the New York College of Pharmacy, served as president of the American Chemical Society and president of the Metropolitan Board of Health. For many years he edited *The Chemical News*. He died on August 25, 1925, at the age of eighty-eight years.

Destruction of the Crystal Palace

THE destruction by fire of the greater part of the Crystal Palace on the night of November 30–December 1 will be widely regretted, for, although its general form and architecture have often made it the subject of good-humoured ridicule, sometimes of derision, it held a unique position and was one of the most famous landmarks of London. As is well-known, it originated from the Great Exhibition of 1851 in Hyde Park, where the Crystal Palace was constructed by Sir Joseph Paxton. When the Exhibition was closed, this "blazing arch of lucid glass" was removed to Sydenham. There it was extended, and finally opened by Queen Victoria and the Prince Consort in 1854. Through public subscription, the grounds became public property in 1913. Though fantastic in appearance, the Palace has for many years been symbolic, and apart from this sentimental loss, its destruction is to be regretted since it had become a centre for music, chiefly choral and orchestral, and for various types of exhibitions. The fire affected the Research Laboratories of Baird Television, Ltd., situated at the Palace, but the part of the building leased by the Baird Company for the production of receiver sets and their testing fortunately was sufficiently remote from the main building not to be damaged in any way. While, therefore, a great amount of research apparatus was destroyed, the delivery of Baird receiving sets will not be seriously affected. Immediate measures are being taken to find alternative accommodation for the Baird Company's large number of research workers and for the re-equipment of the laboratories, and it is not considered that the research programme of the Company will be seriously prejudiced. The fire at the Crystal Palace does not affect the B.B.C. television programmes being broadcast from the Alexandra Palace by the Baird system and by the Marconi E.M.I. system.

Television in the London Area

THE issue of *Television and Short Wave World* of December makes some critical comments on the programmes that have been transmitted from the Alexandra Palace. Complaints are made that intervals, sometimes totalling more than fifteen minutes, occur in a programme of an hour. These intervals are usually filled up by gramophone records, but the owner of the set feels that it is extravagant to run about twenty valves together with a cathode ray tube merely to hear these records. It is unfair to be too critical in the early stages of development, but it looks as if more should be spent on the programmes. Television receivers are being advertised for immediate delivery at prices ranging from 85 to 135 guineas, the picture size being about 12 in. by 9 in. Free demonstrations are given by various manufacturers in London. The Science Museum is still giving demonstrations, and the Southern Railway is giving demonstrations at Waterloo Station to railway ticket holders. Carrington House, a large block of flats in Mayfair, has been equipped for 'bulk reception' of television signals and of ordinary broadcast programmes. The building contains seventy-three flats each of which is fitted with plug points for both kinds of services. The residents of any of these flats can purchase a television or a radio set or both with confidence that the programmes will be produced without interference. It is possible that the actual Coronation ceremony in Westminster Abbey may be televized. The two great difficulties are relaying the signals to the Alexandra Palace and the provision of the necessary bright light.

Derbyshire Caves Exhibition

ON behalf of the Derbyshire Caves Exploration Committee appointed by the British Association, Mr. Leslie Armstrong has excavated Pin Hole, a cave in Creswell Crags inhabited in Upper Palæolithic times and exceptionally rich in prehistoric remains. A preliminary report was published in the *Transactions of the Hunter Archaeological Society*, **4**, part 2, with a diagram showing the brick-earth, red above and yellow below, which underlay the present stalagmitic floor, with layers of slabs fallen from the roof marking periods of exceptional cold. The palæolithic cultures represented are Le Moustier and Aurignac, the latter persisting through the glaciation associated elsewhere with La Madeleine; and the fauna shows severe and temperate conditions alternating. There are chipped pebbles of quartzite, and flint implements of excellent workmanship, nearly all with white patina; also slight engravings on bone, a bone blade regarded as a bull-roarer, as well as a cowrie shell and piece of mother-of-pearl. Mr. Armstrong has also excavated Mother Grundy's Parlour in the same valley, and published an account in the *Journal of the Royal Anthropological Institute*, **55**, Jan.–June 1925, with eight pages of careful drawings of the stone implements mostly of Aurignac types, but with a microlithic industry in the uppermost layer, and chipped quartzite at the base. The cave-earth of the Parlour has large stones from the roof incorporated throughout, not at intervals, and shows the same difference in colour as Pin Hole. Engravings of animals on bone in the Aurignac style and the best of the finds from both sites are now exhibited in the Department of British and Mediaeval Antiquities at the British Museum, near the top of the main staircase, and will, by the kindness of Mr. Armstrong, remain there for the rest of the year.

Romano-British Pottery Kiln from Berkshire

A ROMANO-BRITISH pottery kiln removed intact to the Science Museum, South Kensington, from its original site in Berkshire was exhibited to the public for the first time on December 1. The kiln, now shown with a reproduction of its original surroundings painted by Mr. E. M. Dinkel as a background, is one of two discovered through the introduction of the tractor-drawn plough in the cultivation of a field overlooking the dried-up bed of the River Pang on Woodrows Farm, Compton, near Aldworth, Berks. The deeper ploughing in soil only a few inches deep on chalk turned up a darker earth mixed with potsherds, which on investigation by General W. K. Hardy proved to be due to the presence of two pottery kilns. Of these, one was found to be intact, while the other had been broken up by the ancient potter. The kilns had been constructed by digging an oval hole in the chalk about four feet deep. One half of this was taken up by a rough oven of clay with a front wall of clay and stones, in which was a stoke-hole. A floor of clay, supported by a wall from centre to back, an inch or two below the level of the chalk, served as the stand on which were placed the 'green' pots for firing, heat from the fire passing through holes in the floor. Over the pots had been a dome-shaped cover of clay, which had to be broken at each firing, but of which fragments were found nearby. Pots reconstructed from the numerous sherds collected, as well as coins associated with the find, give a date not later than the beginning of the fourth century A.D. The removal intact of the undamaged kiln entailed not a little skill and ingenuity, as with reinforcement it weighed nearly five tons. Recent archæological discovery, notably in Yorkshire, at Colchester and most recently at Lincoln, have made familiar the kiln and mode of firing employed by the Romano-British potter; but as a rule the conditions of discovery have precluded preservation for general inspection. The kiln now on view at the Science Museum is the only example of the period exhibited in Great Britain.

Exhibition of Kinematography

THE fourth Exhibition of Kinematography, arranged by the Royal Photographic Society, was opened at the Society's premises, 35 Russell Square, London, on November 28 and will remain open until December 19. A large selection of still pictures illustrates the ever-widening scope of kinematography, and includes examples of the work of many producing companies and amateur societies, and of films—scientific, instructional and for purposes of entertainment and publicity. Much recent apparatus, standard and substandard, is on view, this section including exhibits by most of the leading manufacturers. A Vinten gyroscopic tripod for 16-mm. work is particularly worthy of note. Stock manufacturers are also to the fore. Kodachrome is being exhibited in 16-mm. and 8-mm. sizes, the smaller size being not yet on the market in Great Britain. On this stand, too, Messrs. Kodak show samples of 16-mm. work with Pola screens. Messrs. Ilford have staged an exhibit with photographs illustrating the manufacture and testing of Cine products. Examples of their various products, including Dufaycolor, are on view. A comprehensive programme of lectures has been arranged on subjects varying from sound recording to the making of cartoon films. No charge is made for admission to the Exhibition, to the meetings, or for reserving seats.

Dr. E. Bausch and the Optical Industry of America

THE American Society of Mechanical Engineers made its annual awards for distinguished service in engineering and science, and "for great and unique acts of an engineering nature that have accomplished a great and timely benefit to the public" on December 1 to Dr. Edward Bausch and Mr. Henry Ford, when Dr. Bausch received the A.S.M.E. Medal and Mr. Ford the Holley Medal, the former established in 1920 and the latter in 1923. The A.S.M.E. Medal is awarded once a year, "and that only for inventions and improvements of great merit in the technical and public sense". Among the previous recipients have been H. G. Carlson, Dr. Robert A. Millikan, Dr. Ambrose Swasey, and other distinguished contributors to the progress of engineering. In his long and notable career, which began with the construction of his first microscope in 1872, Dr. Bausch has been a constant contributor to engineering progress. At eighty-three years of age, he is still at work, and recently, with other members of the Bausch and Lomb Optical Co., has designed the contour measuring projector. This new instrument is proving itself a valuable inspection device in many types of industry. It is both a microscope and a projection apparatus of the highest quality and great accuracy with which a highly magnified profile of such parts as screw threads, gears, dies, gauges and shapers may be thrown upon a screen or chart for study and comparison.

DR. BAUSCH entered his company's service sixty-two years ago, immediately upon leaving Cornell University. As assistant to his father, John J. Bausch, he is credited with the great expansion of the industry in the United States through the introduction of new technical methods and machine processes to compete with the cheaper hand labour of Europe. Dr. Bausch has for many years been a fellow of the Royal Microscopical Society, and has a wide acquaintance with workers in this field both in Europe and the United States. Not content with his own efforts in building up the optical industry, Dr. Bausch has been conscious of the necessity of educational work to perpetuate his labours. This explains his interest in the establishment of the Institute of Optics, as a part of the Physics Department of the University of Rochester, and the construction of the Bausch and Lomb Physics Building at the University in honour of his father and Captain Henry Lomb, founders of the Bausch and Lomb Optical Co.

Research on Atmospheric Pollution

THIRTY-THREE representatives of local authorities and other organizations co-operating with the Department of Scientific and Industrial Research met at the Fuel Research Station of the Department at East Greenwich on November 30 to discuss the investigation of atmospheric pollution. Dr. G. M. B. Dobson, chairman of the Atmospheric Pollution Research Committee, presented a report on the progress of the investigations carried out under the auspices of the Committee. The Conference noted especially that arrangements are well in hand for the intensive survey of pollution in and around Leicester. After the meeting, the representatives were shown the work of interest to them which is in progress at the Fuel Research Station. Broadly speaking, there are two fundamental and closely related factors involved in the reduction of atmospheric pollution by coal burning—the nature of the fuel and the appliance in which it is burned. The former of these leads to the selection from the varieties available of fuel most suitable for a given purpose. The preparation of coal for the market, by cleaning and grading, assists materially in the reduction of pollution; the cleaning yields a coal of lower ash content, thus decreasing the potential emission of ash in the form of grit, while grading the coal according to size reduces the content of small particles which may be blown from the fuel bed by the draught. The aim in coal-burning appliances is towards greater control over the combustion. This is obtained by uniform air distribution to the fuel and the regulation of air supply, thereby promoting efficient combustion and a reduction of the unburned products passing into the atmosphere. In the domestic field attention has been devoted mainly to the production from coal of a free-burning smokeless fuel, by removing the greater part of the volatile matter which is responsible for most of the smoke nuisance. Appliances have been designed for the burning of such smokeless fuel. Efforts are also being made to test and modify domestic appliances so that raw coal may be burned more efficiently and with a substantial reduction of pollution.

Domestic Cokes

THE Institute of Fuel and the Manchester Association of Gas Engineers held a symposium on domestic cokes in Manchester on November 18. Arnold Marsh examined the question from the point of view of smoke reduction and, discussing the scope of the different smokeless fuels, concluded that all forms of coke would be required. E. C. Evans, on the other hand, fears that an increase in the use of oven coke for domestic purposes would be disadvantageous to the economic production of pig iron. Even now there is a shortage of suitable blast furnace coke. H. J. Hodsman, discussing the relation between the properties of a coke and its behaviour in the grate, emphasized that shallow modern grates cannot be justified on the ground of efficiency on consuming any fuel—whether raw coal or coke. The deeper fuel bed is more rational and this is being recognized by the consumer, for E. W. L. Nicol pointed out that 70,000 such grates convenient for burning coke are sold annually. A. Blackie described two suitable designs of grate which have proved satisfactory. Emphasis was laid on the possibility of activating high-temperature cokes with soda. Prof. J. W. Cobb described how in 1925 it was observed that the reactivity of coke to carbon dioxide is enormously increased by treatment with soda. The chance of industrial use of this has been increased by P. J. Askey's observations that in presence of lime, the addition of even so little as 0·5 per cent sodium carbonate to a coke may produce an adequate increase in the reactivity. R. A. Mott described experiments made with H. H. Thomas in Liverpool Gas Works on alkali activation made under coke oven conditions. These leave little doubt that high-temperature cokes can be made to burn more actively as a result of alkali treatment; but the economic future of the process will depend on other factors. Many existing gas works would find it difficult to introduce a process of pretreating coal into their routine.

Acquisitions at the British Museum (Natural History)

MR. W. FALCONER has recently presented to the Department of Zoology males and females of eighty-four British species of spiders all new to the collection. This valuable gift makes the collection of British spiders in the Museum almost complete. Another interesting accession comprises nine spiders' webs mounted between sheets of glass, the webs being made visible by a black background and the judicious application of baby powder. Prof. G. H. F. Nuttall has presented to the Department of Entomology the whole of the material upon which he based his well-known studies on the human louse. His results, published in *Parasitology* (1917–30), include a very full summary of its relation to typhus, relapsing and trench fever, and other diseases which it carries, and a detailed account of methods of combating lousiness. Among other things Prof. Nuttall demonstrated that the head louse and body louse are not distinct species, but only varieties, possibly showing slight biological differences, of a single species. Recent accessions to the Department of Geology include an extensive series of petrified cones and wood of Araucarian conifers from Patagonia, collected and presented by Dr. F. Mansfield. Many of the specimens have been cut and polished, and the preservation, in chalcedony of various colours, is very good. These fossils were found in the Cerro Alto and Cerro Cuadrado region of Santa Cruz, which has been described as one of the world's most marvellous petrified forests; the material has not yet been fully studied, and the geological age is still uncertain, though it is probably at least as old as early Tertiary. Several hundred invertebrates, mainly corals, from the Palæozoic of Germany and Bohemia, have been collected and presented by Dr. Stanley Smith. The Mineral Department has received by exchange with the Mineralogical Museum, Moscow, an interesting series of specimens from Kola Peninsula and various localities in Central Asia. Lord Ilchester has given a series of pebbles from carefully defined points on the Chesil Beach, which is probably the most remarkable bank of shingle in the world.

Exhibit of the Biology of Water-Supply

A NEW exhibit which has been installed in the Central Hall of the British Museum (Natural History) illustrating the biology of water-supply shows, more fully than its predecessor, the influence of plants and animals on the purification of water for human use. It shows how river-water is purified by storage in reservoirs, followed by filtration through sand. Some of the organisms living in the water of a river find the conditions in waterworks more favourable, and multiply greatly. Thus great swarms of minute plants, and the animals that feed on them, arise in reservoirs. This is sometimes to the advantage of the water engineer, and sometimes greatly to his disadvantage. The beneficial effects include oxygenation of the water by the plants, and the formation of a natural filtering film, more efficient than any artificial film, in stopping the passage of bacteria. This living film, which consists chiefly of microscopic plants, forms on the surface of the sand and gravel of the filter-bed. Trouble arises if the living things in the reservoirs become so numerous as to choke the filters, or are of such a kind as to give an unpleasant flavour to the water. These points are illustrated by specimens, photographs and diagrams. History has shown that, without sand-filtration, mains and supply-pipes are apt to become seriously blocked with animal growths. This is illustrated in the exhibit, which also shows how the excessive growth of microscopic plants can be checked, how wells and springs come to give good or bad water, how sudden and severe outbreaks of iron-bacteria have been known to occur, and the importance of taking drinking water direct from the main, and of keeping household cisterns covered. The Museum is indebted to the staff of the Water Examination Department of the Metropolitan Water Board for help in the preparation of this exhibit.

The Aquarium of the New York Zoological Society

THE fortieth annual report of the New York Zoological Society (June 1936) contains a report on the aquarium, written by the assistant director, Mr. Charles M. Breder, jun. There has been much activity both in improving equipment and collecting fishes and invertebrates for the aquarium. Besides this, many fishes have been hatched, including whitefish, Chinook salmon, rainbow trout and muskallunge, and the young handed over to the New York City Water Department for distribution in public waters. Studies on the nature of electrical energy discharged by such fishes as the electric eel were continued by Mr. Coates. After many experiments, it was found that the electricity discharged by an eel could be made to light a neon tube, and this led to a daily demonstration for the benefit of the public. Mr. Breder himself is studying details of reproductive habits of fishes, including five species of sunfish, the stickleback, *Apeltes quadracus*, and the catfish, *Villarius catus*, and has published several papers on this subject. Besides work by the staff, a number of visitors have made use of the aquarium facilities during the year.

The Parliamentary Science Committee

THE annual general meeting of the Parliamentary Science Committee was held at the House of Commons on November 26, the Earl of Dudley presiding. The officers elected for the ensuing year were : *President*, The Earl of Dudley ; *Chairman*, Sir Arnold Wilson ; *Vice-Chairman*, Prof. B. W. Holman ; and *Hon. Secretary* and *Treasurer*, Mr. H. W. J. Stone. According to the annual report, four more institutions were affiliated to the Committee during 1936, and others have the subject under consideration. The total aggregate membership of the affiliated institutions now exceeds 100,000. During the last session, the Committee was active in approaching Government departments, and in promoting questions in Parliament on a variety of topics. The outstanding feature of the year's work has been the consideration of a memorandum how best to finance and develop scientific and industrial research. The investigations into this subject have not yet been completed. During the past year the following members of parliament have joined the Committee: Lord Melchett, Prof. J. Graham Kerr, Mr. Andrew MacLaren and Sir Philip Dawson.

Bright Fireball of November 14

AT about 8.45 p.m. on November 14, a very bright fireball was seen by a number of people in different parts of Ireland. All the accounts agree in describing it as extremely brilliant, showing lights of various colours—white, blue, and red—and moving fairly slowly earthwards. Some of those who saw it allege that it lighted up the country, a road being visible for half a mile ahead, or the earth being as bright as day. Many people were terrified by the apparition, and one girl collapsed with fright. Most of the accounts come from Dublin and Wicklow, but it was also seen in Co. Tipperary, and a correspondent there describes it in terms almost similar to those used by others in eastern Ireland, namely, "it seemed very close at hand and lighted the whole place up". A report from Co. Armagh, Northern Ireland, asserts that three minutes after its disappearance a dull rumbling noise like distant thunder was heard. No one has given its position at beginning or ending with reference to the stars ; indeed it does not appear that any stars were visible, at least for the observers in eastern Ireland. For this reason it is quite impossible to compute its path. Judging by the vague descriptions of its direction, it was probably falling nearly vertically somewhere about the middle of Ireland, probably a little towards the west.

Three Large Sunspots

A CONSPICUOUS feature of present solar activity is the appearance on the disk at the same time of three large sunspots, each being visible to the naked eye. Foggy weather in London and elsewhere on November 28 provided almost ideal conditions for direct observation without a telescope, and a number of people, who were previously quite unaware of the existence of the spots, discovered them independently for themselves. From a photograph obtained at the Royal Observatory, Greenwich, on November 27, the following data are derived :

Date on Disk	Central Meridian Passage	Latitude	Area
Nov. 23–Dec. 5	Nov. 29·3	17° N.	1400
Nov. 23–Dec. 5	Nov. 29·4	11° S.	1000
Nov. 25–Dec. 8	Dec. 2·2	14° S.	1400

Areas are corrected for foreshortening and are given in millionths of the sun's visible hemisphere.

Under favourable conditions, a single spot of area 500 millionths may be detected without a telescope. Including the three present spots, nineteen naked-eye spots have already been recorded this year. Since the frequency curve of these large spots approximates closely to the more representative curve given by all spots or by their mean daily area, an even greater number of large spots may be expected in 1937–38, the epoch of the anticipated maximum of the present 11-year cycle.

The Night Sky in December

ON December 22^{d} 0^{h} the sun enters, at the winter solstice, the sign Capricornus ; in the latitude of London the nights are then 16¼ hours in duration. The moon is new on December 13 at $23\frac{1}{2}^{\mathrm{h}}$ and full on December 28^{d} 4^{h} U.T. At new moon an annular eclipse of the sun is visible in the antipodes (local time December 14)—the central line, along which the duration of annularity is 5½–7½ min., crossing

Australia and the North Island of New Zealand. Among the seven lunar occultations visible at Greenwich, the disappearance of *A* Tauri (mag. 4·5) may be noted on December 25 at $20^h\ 0{\cdot}9^m$ at 120° from the north point of the moon's disk. Of the planets visible, Venus is a conspicuous object (mag. $-3{\cdot}6$ to $-3{\cdot}7$) setting about $19^h\ 0^m$ in mid-December. On December $17^d\ 17^h$ the planet is in conjunction with the moon, below which it will be situated 6°. Mercury is not very accessible to observation, but may be seen during the last week of the year near the south-west horizon at 17^h. Mars rising after midnight is in Virgo; on December 21 it passes 3° north of the bright star, Spica. Saturn, in Aquarius, sets about 23^h in mid-December; on Dec. $20^d\ 19^h$ the planet is in conjunction with the moon, and on December 28 the sun will be in the plane of the rings, the minor axis of which is now about 2″. In addition to the planets, the skies offer at any time during a fine night in December an attractive field for observation. At 22^h in the middle of the month, the constellations of Cassiopeia, Perseus, Andromeda, Taurus and Aries are near the meridian, whilst the stars of Orion, Sirius, Procyon, Castor and Pollux are south-east and eastwards. The Geminid meteor shower should be looked for on or about December 11, the radiant point being at R.A. $7^h\ 12^m$: Dec. 33° N. The light variations of Algol may be observed at about December $1^d\ 0^h$: $3^d\ 21^h$: $6^d\ 18^h$: $18^d\ 5^h$: $21^d\ 2^h$: $23^d\ 23^h$: $26^d\ 20^h$ and $29^d\ 17^h$.

Announcements

THE Buchan Prize of the Royal Meteorological Society for 1937 has been awarded to Mr. C. S. Durst, for papers contributed to the *Quarterly Journal* of the Society during the years 1931–35.

THE Mozelle Sassoon High Voltage X-Ray Therapy Department of St. Bartholomew's Hospital, London, will be opened by Mrs. Meyer Sassoon on December 10 at 2.30 p.m., when Lord Rutherford and Lord Horder will speak. A memorial plaque to Dr. R. G. Canti, late clinical pathologist to the Hospital, will be unveiled by Dr. Malcolm Donaldson, director of the Cancer Department.

MESSRS. W. WATSON & SONS, LTD., of 313 High Holborn, London, W.C., are holding their fourth Annual Exhibition of Microscopes in the Central Hall, Westminster, on December 7–11. In connexion with the Exhibition, several cinematograph films will be shown, and the following lectures will be given: "Science and Vinegar Brewing" (Mr. Sarson); "The Romance of Shell Life" (Mr. F. Martin Duncan); "Old Instrument-makers" (Mr. R. S. Whipple).

DR. FRICK, the German Home Office Minister, has ordered that specimens of blood should be examined for the presence of alcohol according to Widmark's method in the case of persons apparently under the influence of drink when involved in motor accidents.

ACCORDING to the Soviet Union Year Book Press Service, the large Soviet Medical Encyclopædia has now been completed. It consists of 35 volumes, containing 6,396 articles and 80,000 terms used in medicine and allied sciences; 20 academicians, 692 professors and 1,006 other scientific workers have taken part in the production of the Encyclopædia under the editorship of Prof. N. A. Semashko.

THE Leningrad branch of the All-Union Institute of Experimental Medicine is collecting documents relating to the life and work of the late Prof. I. P. Pavlov. The documents are to be added to the collection already in existence at the Pavlov Museum founded by the Leningrad branch. A commission is approaching men of science and scientific institutions abroad for gifts of any material they may have in their possession relating to Pavlov.

WE are informed that the price of Osborn's "Monograph of the Proboscidea" is 20 dollars (NATURE, Oct. 31, Supp. p. viii, and Nov. 21, p. 860).

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Lecturer in mechanical engineering in the St. Helens Municipal Technical School—The Director of Education, Education Office, St. Helens (December 8).

Lecturer in mechanical engineering and lecturer in electrical engineering in the Norwich Technical College—The Principal (December 9).

Lecturer in mechanical engineering in the West Hartlepool Technical College—The Secretary for Education, Education Offices, West Hartlepool (December 9).

Temporary assistant engineers, engineering assistants and junior engineering assistants to the Ministry of Transport—The Establishment Officer, Ministry of Transport, Whitehall Gardens, S.W.1 (December 11).

Junior research chemist for work on fuel problems at the Bone Research and Development Association, Ltd.—Prof. W. A. Bone, Imperial College of Science, S.W.7 (December 11).

Research physicist to the Printing and Allied Trades Research Association—The Director of Research, 10 Robin Hood Court, Shoe Lane, London, E.C.4 (December 21).

Chief mining engineer to the Safety in Mines Research Board—The Establishment Officer, Mines Department, Dean Stanley Street, S.W.1 (December 31).

Imperial economic botanist at the Imperial Agricultural Research Institute, New Delhi—The High Commissioner for India, General Department, India House, Aldwych, W.C.2 (January 2).

Professor of animal pathology in the University of Cambridge—The Vice-Chancellor (January 12).

Research physicist to the British Cotton Industry Research Association—The Director of Research, Shirley Institute, Didsbury, Manchester.

Principal of the Kadoorie Agricultural School, Mount Tabor, Palestine—The Chief Secretary to the Government of Palestine, Jerusalem.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 976.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Mechanism of Thermal Change in Gaseous Organic Compounds

INVESTIGATIONS in this laboratory have shown that thermal change in gaseous organic compounds commonly leads to the formation of paired products through a single chemical process, so that, although the rate of change in the reactant is determined solely by initial concentration and temperature, the relative rates of formation of the products may be determined by other conditions. In such cases the initial rates of reaction show acceleration, the $x - t$ graphs being linear, or curved towards the x-axis; but after a relatively short period the slopes of the graphs suddenly diminish. Further, the main process seems generally to be associated with a primary or *background process*, represented by,

$$A \rightleftharpoons B\ (+C),$$

leading to equilibrium in the system A, B, (C).

The main process seems to be initiated by binary collisions AB, collisions AA, and generally also BB, leading only to change in the equilibrium system. The main process may be represented by,

$$\begin{array}{ccccc} a & b & c & d & e \\ A + B \rightarrow & A'B' \rightarrow & A'B' \rightarrow & A'B' & \begin{smallmatrix} \nearrow C \\ \searrow D \end{smallmatrix} \\ \text{Molecules} & \text{activated complex state} & & \text{unstable intermediate} & \text{paired products} \end{array}$$

The change $c \rightarrow d$ is such that the probability of reversal is very small, and it is the rate of this process which we generally measure. Since the products which are formed simultaneously may be, on one hand, products of condensation, and on the other, products of disruption of the reacting molecules, it is suggested that these survive as entities to the *unstable intermediate* stage, and that free radicals are not accountable for the processes involved.

Re-investigation of the data obtained by Dr. Hockin, Dr. Pearce and myself from the study of the thermal decomposition (550°–630°) of ethane, and of ethane – ethylene – hydrogen equilibrium mixtures, has thrown some light on the whole problem of the thermal changes in simple organic compounds. In both cases methane and condensation products are formed, but in the background of the processes which give rise to these products is the equilibrium reaction represented by,

$$C_2H_6 \rightleftharpoons C_2H_4 + H_2.$$

However, in this case the background reaction can be studied independently, and a great deal is known about it. Also, by working with ethane – ethylene – hydrogen equilibrium mixtures, we can virtually eliminate the disturbing effect introduced by the operation of the background reaction when working with pure ethane. It is possible to make up an unlimited number of mixtures in which the ratio $(C_2H_4)(H_2)/(C_2H_6)$ corresponds to equilibrium conditions at the temperature of the experiment, and using the computative method described in one of our papers[1], I have found that the rate of formation of the products, expressed in terms of the rate of disappearance of 2-carbon hydrocarbon, conforms to the expression,

$$d(CH_4 + R)/dt = K(C_2H_6)(C_2H_4),$$

with reasonable exactitude in the case of about a hundred experiments.

Starting with pure ethane, it is found that the initial rate of reaction is accelerated. This may be accounted for qualitatively by the fact that the ethylene concentration is increasing from the commencement. However, the acceleration is greater than can be accounted for in this way, and the fact that the break does not occur in the $x - t$ graph until some little time after the ethylene concentration has reached a maximum suggests that the acceleration may be partially due to some chain mechanism arising from the background reaction. After the break, the rate of reaction seems to conform to the bimolecular equation. The ratio $(CH_4)/(CH_4 + R)$ seems to vary between limits 0·5 and unity with the hydrogen concentration, but no quantitative relationship has been worked out. The bimolecular reaction involving ethane alone results only in the formation of ethylene and hydrogen, and the bimolecular condensation of ethylene, as studied by Pearce, seems to be a heterogeneous process.

The work carried out by Dr. Seddon and myself on acetaldehyde was that in which it was shown originally that the *paired products* may result from a single chemical process. They are methane and carbon monoxide, which constitute the main product when the reaction is conducted in an empty tube, and propylene, carbon monoxide, and water, which may constitute the main product when the tube is packed. The thermal decomposition process is accelerated initially; and, from analogy with the case just considered, it seems fair to associate this process with the development of a system represented by,

$$CH_3.CHO \rightleftharpoons CH_2{:}CHOH,$$

in the background. The constituents of the system are known, though nothing is known about their equilibrium relations.

The thermal decomposition of methyl nitrite has been studied by Mr. A. G. Carter and myself. Contrary to the conclusion of Steacie and Shaw, we find that the decomposition process shows strong initial acceleration, and that paired products result, the processes being represented by,

$$\begin{aligned} 2\,CH_3NO_2 &= 2\,NO + CH_2O + CH_4O, \text{ or} \\ &\ N_2O + 2\,CH_2O + H_2O. \end{aligned}$$

There is evidence here that the process must be bimolecular. However, though there is plenty of evidence to show that methyl nitrite does not behave like a normal ester, there is no evidence as to the nature of a background process, should such exist. The thermal decomposition of methylamine has been studied by Messrs. Bosanquet, Carter, Wilshire and myself, in continuation of the work of Emeléus and Jolley. Their work suggested that the two methods of decomposition represented by,

$$CH_3NH_2 = HCN + 2\,H_2, \quad \text{and}$$
$$CH_3NH_2 + H_2 = CH_4 + NH_3,$$

are related. We find further evidence in support of this view, and also that the processes are initially accelerated. The process represented by the first equation is definitely reversible, and it can be supposed that a background reaction operates in this case, though its nature is again unknown.

A similar mechanism must operate in the case of other gaseous reactions to which I have made reference in recent letters to NATURE.

We have also studied the thermal decomposition of certain 3-carbon compounds, but detailed analysis shows that the processes are extremely complex. One can, in such cases, express the rates of decomposition, if measured by observing increase in pressure at constant volume, by means of an equation analogous to that representing unimolecular change. Taking the two sets of results together, however, it seems to me that such procedure is likely to be much more misleading than helpful.

M. W. TRAVERS.

Action of Co-zymase as the Specific Co-enzyme of Lactic Dehydrogenase from Heart Muscle

EARLIER work on the mechanism of enzymatic dehydrogenation has shown that, in presence of a thermolabile apo-dehydrogenase of protein character, co-zymase takes up hydrogen from a substrate and is thereby reduced to a dihydro-form[1]; the dehydrogenation of alcohol may be represented by the equation

$$\text{alcohol} + D^A\text{-}Co^{I} \rightleftharpoons \text{aldehyde} + D^A\text{-}Co_{I}H_2 \qquad (1)$$

where D^A is the specific alcohol apo-dehydrogenase and Co^I co-zymase. The apo-dehydrogenases are specific with respect to substrates and to one or other of the two known co-dehydrogenases, co-zymase (Co^I) or Warburg's co-ferment (Co^{II})[2]. Recently, we showed that lactic apo-dehydrogenase from heart muscle and alcohol apo-dehydrogenase from yeast are not identical, but both form active holo-dehydrogenases only with Co^I and not with Co^{II}[3].

Green and Brosteaux[4] have just confirmed our result that lactic dehydrogenase is not activated by Co^{II}, but have not decided whether the necessary co-dehydrogenase is identical with Co^I. Our earlier proof of the identity of lactic co-dehydrogenase with co-zymase, based on parallelism between fermentative and co-dehydrogenase activity, is confirmed conclusively by the following experiments, which show that alcohol co-dehydrogenase and lactic co-dehydrogenase are completely interchangeable. The identity of the former with co-zymase is quite certain.

(1) 2·0 ml. $M/2$ sodium lactate, 1·4 ml. $M/2$ disodium hydrogen phosphate and 0·1 ml. lactic dehydrogenase (D^L) from heart muscle (clear solution) were mixed in an absorption cell and the extinction (ε) at $\lambda = 334$ mμ was measured photo-electrically. After addition of 0·4 mgm. co-zymase, the extinction increased rapidly, corresponding with the formation of reduced co-enzyme (Fig. 1). Equilibrium was reached after 10 minutes. After a further 15 minutes, 0·1 ml. $M/10$ sodium pyruvate was added (*a*) which caused the extinction to fall rapidly to a value representing the absorption of the excess of pyruvic acid. This experiment indicates the reversibility of the process

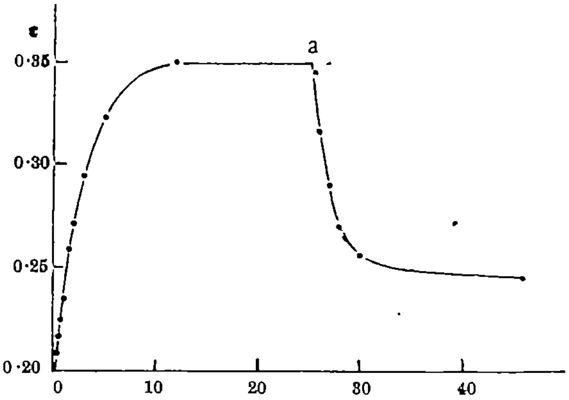

FIG. 1.

$$CH_3.CHOH.COOH + D^L\text{-}Co \rightleftharpoons CH_3.CO.COOH + D^L\text{-}CoH_2 \quad . \ . \ . \ . \quad (2)$$

The effect of pH and temperature on this equilibrium is being further investigated.

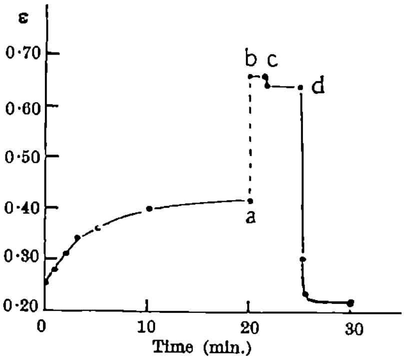

FIG. 2.

(2) In a similar experiment (Fig. 2), after production of the reduced co-enzyme, the mixture was heated (*a*) for 5 minutes at 75°, thus destroying the lactic apo-dehydrogenase. After filtration, the extinction of the clear filtrate was again measured (*b*). The increase is due to a displacement of the equilibrium by rise of temperature in favour of the reduced co-enzyme prior to destruction of the enzyme. No reaction occurred on addition of 0·1 ml. $M/100$ acetaldehyde (*c*), but on subsequent addition of 0·1 ml. alcohol apo-dehydrogenase from yeast (*d*),

the extinction fell immediately to the initial value. This action of acetaldehyde in presence of alcohol apo-dehydrogenase indicates that the reduced co-enzyme was identical with dihydro-co-zymase.

(3) In a mixture of 0·2 mgm. co-zymase, 0·3 ml. $M/2$ phosphate buffer $pH=7\cdot6$, 0·1 ml. alcohol apo-dehydrogenase, 0·2 ml. absolute alcohol and 3·5 ml. water, dihydro-co-zymase was produced and recognized by its characteristic absorption at 334 mμ (Fig. 3). After attainment of equilibrium, the apo-dehydrogenase was destroyed by heating (*a*); the extinction rose to (*b*) owing to a slight turbidity. Addition of 0·1 ml. $M/10$ pyruvate caused an immediate increase to (*c*), due to the pyruvate itself, but on further addition of 0·1 ml. lactic apo-dehydrogenase (*d*), the extinction fell by an amount representing the reoxidation of the dihydro-co-zymase. It follows that dihydro-co-zymase can act as the prosthetic group of lactic dehydrogenase in the reduction of pyruvic acid to lactic acid.

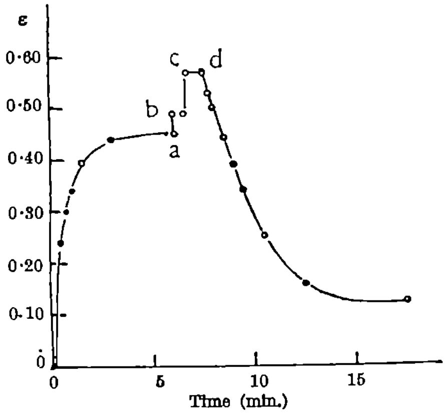

FIG. 3.

These three experiments show that the co-enzyme of lactic dehydrogenase is identical with that of alcohol dehydrogenase and therefore with co-zymase. The reduction of pyruvic acid to lactic acid in muscle glycolysis probably involves dihydro-co-zymase. Further details will be given elsewhere.

The Sterckfontein Ape

IN NATURE of September 19, Dr. R. Broom, of Pretoria, has given an account of the important discovery of a Pleistocene anthropoid skull at Sterckfontein, near Johannesburg, Transvaal, and has supplemented it simultaneously by a series of excellent photographs both of the site and specimen which have appeared in the *Illustrated London News*. In NATURE of October 24, p. 719, he has given a figure and description of the teeth. He maintains that the Sterckfontein specimen belongs to the same genus *Australopithecus*, although to another species, as the Taungs ape, and that both are hominoid, and not nearly related to any of the existing species of anthropoids.

In examining the cast of the Taungs specimen in the British Museum, and the photographs of the teeth published by various authors, notably by W. Abel[1], the conclusion could not be avoided that these teeth are not human at all but are more like those of the gorilla. As regards the skull of the baby specimen from Taungs, it shows features which are decidedly gorilloid. The concave profile of the face (taken to be chimpanzoid by Dart) can easily be explained by deformation, proof of which is the crack at the root of the nasals. The nasals themselves are fairly big, but appear smaller than they really are, because the lower end is broken off, and the nasal aperture therefore distorted. Other features which the skull has in common with the gorilla are the length of the brain case, and the fact that the suture between the maxillary and the zygomatic runs medially to the masseteric knob, whereas in the chimpanzee, for example, it runs laterally. The size of the Taungs ape is smaller than that of any recent gorilla of corresponding age. The Sterckfontein skull is that of an adult animal. Its size again is smaller than that of the existing gorilla. But this reduction in size is on about the same level as in the Taungs ape. The teeth figured by Dr. Broom are quite unlike those of man or of the chimpanzee. In both of these they are roundish in outline, and the heel of the last molar is shortened and the individual cusps more or less fused into a ridge. In the Sterckfontein skull, and in the gorilla, the cheek teeth are more rectangular in cross-section, and the last molar has a well-developed heel with two distinct cusps (and a postero-external style). The structure of this tooth in Dr. Broom's specimen can be matched by that found in a female gorilla from the Okuni district, South Nigeria (Brit. Mus. No. 7.1.8.4).

Dr. Broom has maintained that one of the most important features proving the affinity of *Australopithecus* and man was the fact that the lateral incisors of the upper jaw and the canines meet, a feature which he thinks does not occur in apes. This may be true in normal chimpanzees and gorillas. But it is not quite true in the pigmy chimpanzee (*Pan satyrus paniscus*) found south of the Congo, where the space between these two teeth has become very small indeed. This animal, as has been pointed out before, presents a case homologous to *Australopithecus*[2]. The small size, the dome-shaped forehead, the shortness of the face which is responsible for the crowding together of the teeth, are the same in both. It is, therefore, very probable that *Australopithecus* was a pigmy gorilla. From the relative size of the two specimens known and the smallness of the canine teeth, it appears that both were females.

The fact that Dr. Broom's specimen does not represent an ancestral form of the hominoid line does not detract from the extreme value of the discovery. It is to be hoped that he will be able to continue his researches, and to elucidate the history of anthropoids in Africa, an undertaking quite as important and interesting as that of the ancestors of man himself.

Enamel Protein

HUMAN dental enamel contains about one per cent organic matter[1], and it is well established on histological evidence that the structure of enamel consists of a mesh-work of organic matter in which inorganic salts (mainly calcium phosphate) are deposited in an orderly arrangement, resembling prisms. It is to be noted that newly formed enamel is covered with a layer of organic matter (Nasmyth's membrane), and also[2] that there is more organic matter in enamel near the junction with the underlying tissue, the dentine, than in that portion equidistant from the dentine and the surface of the tooth.

Fifty years ago Thompson[3], in describing human dental enamel, referred to "an organic matrix of horny matter, keratine", and it may be said that the organic matter associated with enamel has always been regarded as keratin. Most authorities agree in referring to keratins as proteins with a high sulphur content, although Block and Vickery[4] do not regard "a high proportion of cystine as necessarily characteristic of keratins". It has been stated that "the linkages binding sulphur into the protein molecule are uncertain"[5]; this uncertainty may be said to extend to organic substances containing sulphur, of which two new examples have recently been described by Mueller[6] and Baernstein[7]. It will be seen below that the presence of sulphur can readily be demonstrated in some keratins, but it may be said that the demonstration is incomplete so far as enamel protein is concerned. Rosebury[8], who recently published a detailed study of enamel protein, described it as "showing the chemical characteristics of keratin". In this work he used the lead test for labile sulphur, which, he says, "at best is not a delicate reaction".

In separating the organic material in enamel from the inorganic part, one of the difficulties with which I met was the scarcity of suitable human material. It was considered that biochemical methods of examination into the nature of this protein offered advantages over methods involving the use of stains and microscopy. One method of separation of the inorganic matter from the organic consists of reducing whole teeth to powder, then suspending the mass in a liquid of which the relative density is midway between that of the inorganic and the organic portions. This method was not continued as it was found that the density of the organic matter in dentine was too near that of the organic matter in enamel.

I took advantage of the fact that the inorganic salts of enamel are soluble in acetic acid, while the organic part appears to be insoluble. While this means of separating organic matter from inorganic has been found convenient, it is realized that the acid may have some action on the protein. For the purposes of the present work, it has been assumed that acetic acid does not dissolve organic matter from the dentine. This assumption is supported by histological evidence.

In an attempt to elucidate the nature of enamel protein, the following method was used: sound (non-carious) human teeth were scraped clean, dipped in 20 per cent nitric acid for a few seconds to remove surface contamination, and washed in distilled water. The roots were cut off and discarded, and any remaining pulp-tissue removed. The crowns were next exposed to the action of 10 per cent acetic acid as a decalcifying agent and agitated mechanically for twelve days. In this way the greater part of the enamel was removed from the dentine and appeared in the acid as a white powder, separation being aided by shaking with glass beads. The pieces of dentine were removed, and the white powder allowed to settle for 24 hours, when the bulk of the fluid was poured off and tested for protein with picric acid and with sulpho-salicylic acid, both with negative results. The powdery mass was next shaken up with distilled water and a few drops of nitric acid added. The enamel protein was thrown out by centrifuging, then washed and centrifuged several times until the washings appeared neutral to B.D.H. universal indicator.

The application of this method resulted in the separation of the protein as a flocculent, yellowish-brown mass, with a density near that of water. Nitrogen determination gave a positive result, but the percentage figure arrived at (9·2) is of doubtful value on account of uncertainty as to the freedom from contamination of the protein. Heated on platinum foil to redness, the protein disappeared leaving only the faintest of marks. It appeared unchanged after exposure for one hour to boiling strong potassium hydroxide. With Millon's reagent the protein gave a marked red colour. Negative results were seen when the sodium nitro-prusside test for sulphur as given by Cole[9] was applied. The procedure was varied by exposing the protein to 1 per cent potassium hydroxide at 37° C. for twenty-four hours, and also by boiling it with 25 per cent potassium hydroxide for one hour. The sodium nitroprusside test gave a negative result after both these forms of treatment. As controls, fragments of human nail, sheep's wool and horse hoof were exposed to acetic acid for ten days and then tested for sulphur by the nitro-prusside method, with a positive result in each case. Other reducing agents were used in attempts to reduce any cystine present to cysteine: tin exposed to hydrochloric acid, also zinc exposed to cadmium chloride then to hydrochloric acid. Both these reducing agents were used in place of potassium cyanide, but gave negative results. It was noticed, however, that when potassium cyanide was used as a reducing agent, the protein went into solution.

It is thought that it should be possible to get the protein in a pure form by the use of potassium cyanide followed by the use of dialysis. The observation that the action of potassium cyanide is to dissolve this protein may be contrasted with the negative results observed with the nitro-prusside method. It is thought that neither the acetic acid used to decalcify the teeth, nor the presence of calcium salts from the enamel or the dentine affected the result. Preliminary examination of the protein by Mr. W. T. Astbury using X-ray spectrography has suggested that the X-ray picture differs from that given by some keratins.

The organic material appears to be a protein containing tyrosin and resembling reticulin, and further work to determine its nature is in progress.

The work was carried out with the aid of a grant from the Medical Research Council, for which grateful acknowledgement is made.

Thermal Stratification in Lakes

EARLY in this century, Thienemann[1] and Naumann[2] described the physical conditions in deep freshwater lakes in the temperate zone. They found a yearly cycle of events which depended on the thermal stratification of the water. Their findings, and the conclusions they drew from them, can be summarized briefly, as follows. In winter and early spring, the temperature and density of the water mass is almost uniform from the surface of the lake to the bottom, so that the viscosity of the water is the only hindrance to mixing by wind. In late spring and early summer this state of affairs changes because the surface layers become warmed up by increased radiation from the sun and conduction from a warmer atmosphere, and by the inflow of warmer rivers. The result of this warming is that, in summer, a warm upper layer of less dense water, the epilimnion, comes to lie over a cold deeper water mass, the hypolimnion. The two are separated by a region of very steep vertical temperature gradient, the thermocline, with the result that mixing by wind is impossible.

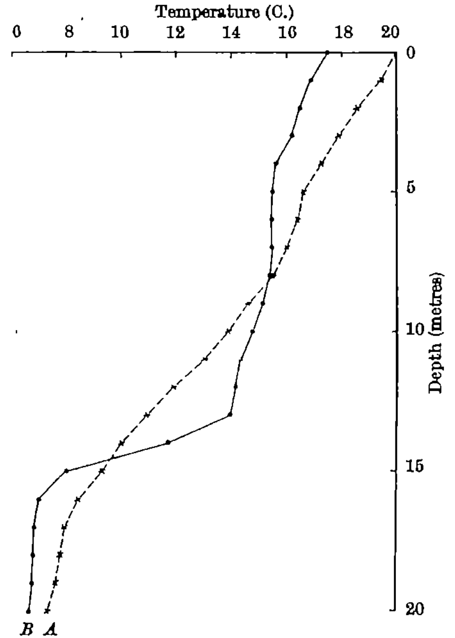

FIG. 1.

Since photosynthesis can only take place in the upper layers of the water, that is to say in the epilimnion, the available supply of salts for the planktonic algæ must be that which is dissolved in the water above the thermocline. Thus the continuous existence of the thermocline, with the consequent separation of the epilimnion from the hypolimnion, has important biological consequences, namely, the restriction of algal growth by limiting the salt supply. Thienemann and Naumann suppose that this state of separation exists continuously for the whole summer and well into the autumn, in fact throughout the period of maximal solar radiation. Consequently, the salt supply of the upper layers of water can first be renewed in late autumn, when the thermocline breaks down owing to the cooling of the epilimnion. Then free circulation is again possible, and water richer in salts from greater depths can reach the surface.

We have taken regular temperature observations in the north basin of Windermere extending over several months during the spring and summer of 1936. Our findings do not agree with those of the Continental workers, for the thermocline in Windermere, in this year at any rate, can be very unstable. It can appear and disappear in the course of a few days. Sometimes the state of affairs postulated as permanent by Thienemann and Naumann was found, but at other times there was a uniform temperature gradient from the surface to a depth of 20 metres without any trace of a thermocline. The presence or absence of a thermocline can be correlated with the weather. When it is calm there is no thermocline at all, but windy weather is always followed by the appearance of a region of sharp temperature gradient. The depth at which the thermocline appears depends on the strength of the wind; the stronger the wind the greater the depth. It can occur at any depth in Windermere from just below the surface down to 15 metres. After a thermocline has been formed during a period of active mixing by wind, it disappears again within two days if the weather becomes quiet.

In Fig. 1 the curve *A* represents the state of affairs during the period August 25–29, 1936, when the weather was uniformly fine and windless. Curve *B* obtained on August 31, 1936, at the same place, shows that a thermocline had been formed at a depth of 13–15 metres by a strong wind blowing on the intervening day, August 30.

Some of the factors which lead to the formation of the thermocline are not yet clear, and nearly all those concerned with its disappearance are still obscure. But the biologically important fact remains, that the thermocline is not a continuous feature of the summer conditions in temperate lakes. Sometimes it is not there at all, and when it appears the depth at which it occurs varies greatly. This must lead inevitably to a re-orientation of ideas about the biological productivity and the heat budgets of temperate lakes.

The Half-Drill Strip System Agricultural Experiments

PROF. R. A. FISHER and Dr. Barbacki have recently published a paper in the *Annals of Eugenics* entitled "A Test of the Supposed Precision of Systematic Arrangements"[1]. There is a good deal in the paper with which I am not in agreement and with which I hope to deal elsewhere, but a letter from a friend of mine in Australia, who had heard at second-hand that Fisher's "results showed not only that the half-drill strip failed to give a valid estimate of error but was less accurate", shows that it would be better not to let such rumours get a start, for they are quite unfounded.

In the paper, the crop on a uniformly treated field was assigned to two imagined treatments *A* and *B* on a systematic plan in which eight strips of the width of a half-drill were assigned to *A*, and eight to *B*, in the usual arrangement of an eight comparison half-drill strip experiment. Apart from the fact that one should have at least ten comparisons—in Beaven's original paper[2] there were 26—the representation is a fair one.

The authors, for the purpose of ascertaining the degree of precision which is obtainable from the systematic arrangement in question, have taken the weights of grain, not from the total area of each of the 16 strips, but from 12 sections of each strip, and have treated these 192 sections as if they were independent half-drill strips—in fact they have called them half-drill strips—and from the 96 comparisons they have calculated a standard error to represent the precision which they suppose an advocate of systematic arrangements would attribute to the method. But, of course, the sections of a half-drill strip are not in fact independent, and in this case are markedly correlated, so that the figure which they obtain is much too small to account for the observed difference between the *A*'s and the *B*'s—and they draw conclusions adverse to the systematic arrangement and not to their own method of calculation.

The procedure adopted, of dividing up the long strips, is that which Dr. Beaven[2] originally proposed in 1922, namely, weighing the sheaves off equal segments of his half-drill strips and calculating the error from these weights; but so early as 1923, I pointed out[3] that this method would probably give a fallaciously small value, and since then it has been customary to regard the whole length of the strip as the unit in the calculation.

Had Prof. Fisher and Dr. Barbacki calculated the error on that basis[4,5], they would have found a standard error of 2·37 per cent of the average yield, while the actual difference between the *A*'s and *B*'s amounts to 1·75 per cent; that is, the difference between two things which should be the same within the error of random sampling is in fact no more than 0·75 times the standard error.

The authors' practical demonstration of the correctness of my *a priori* reasoning is, of course, very gratifying to me, but I must nevertheless insist that their paper has no bearing whatever on the error of present-day half-drill strip experiments.

Genetics in the Universities

THERE are two technically distinct branches of experimental biology: physiology and genetics. The first is concerned with the processes by which life is maintained and developed, the second with the determinants of these processes which are identifiable in heredity. The distinction between the two methods of analysis is convenient, but not of course rigorous; experimental embryology attempts to connect them. Across this subdivision cuts the much older one between botany and zoology. However difficult it may be to draw the line between plants and animals, in descriptive work it is clearly necessary to draw a line somewhere. But in experimental analysis it is not merely unnecessary; it is often destructive. This is perhaps not so true in physiology as in genetics, since there is a bifurcation in the method of development of plants and animals and even in the molecular structures used in their development. But this bifurcation begins outside the cell nucleus. Within the nucleus the distinction between plants and animals in structures both molecular and super-molecular to a great extent breaks down. Nuclear division and sexual heredity are the same in principle in the fly and the flowering plant.

This view of the unity of living things in their genetical aspects is so clear and important that it has been recognized by the British Association through the appointment of a committee to co-ordinate genetics and cytology in the different sections, and it is to be hoped that the confusion of the past will be remedied in this way. But it is in teaching that failure to recognize the unity of biology leads to the most serious confusion and failure of adjustment to modern changes. The universities present a surprising spectacle of variation in their methods of teaching genetics and cytology. In a few, the processes of heredity and their underlying mechanism are described as one integrated whole; they are described together to the botany and zoology students; the syllabus is revised to bring it into line with recent research; and questions are regularly asked on the subject in examination papers. In other universities, any or all of these conditions may be omitted. In one, a student may hear four descriptions of chromosome behaviour, in morphological, genetical, physiological, agricultural or medical courses; and these descriptions may or may not be required by his syllabus or by his examiners. In another, a student may hear a morphological account of the cell which he has to relate as best he can with an entirely unco-ordinated account of heredity, if indeed he has received any account of it at all.

In our opinion, whatever the object of training in botany or zoology, such a method defeats that object. The physiologist who does not understand what part genetic differences may play in his experimental material, the taxonomist who can distinguish his species but does not know what different mechanisms of heredity perpetuate them or what sterility barriers separate them, alike seem to be in danger of wasting their time. The teacher who describes the types of organism (sometimes very numerous types) and does not show how each varies, or who explains the structure of everything and the mechanism of nothing, seems to be in danger of wasting his students' time. Above all, he is likely to deter the most intelligent students from continuing their studies in what may appear to be a purely scholastic inquiry.

Teaching how meiosis works without ever arriving at its results in crossing-over and segregation, teaching *Drosophila* genetics without mentioning how the spores of fungi show the properties inferred in the sperm of *Drosophila*: throwing away, in a word, the glorious opportunity that genetics now offers us of uniting the sciences, seems to be the consequence merely of lack of co-ordination. Departmental independence in the universities should be accompanied by departmental co-operation. Uniformity between the universities is the last thing we want, but the student surely has a right to expect internal consistency. Is it too much to hope that the Boards of Studies which all over Great Britain will soon be considering their university courses should ask themselves, first whether their syllabuses represent the fundamentals that recent research can offer to the intelligent student; secondly, whether the teaching of genetics and cytology is satisfactorily co-ordinated between the botanical and zoological sides; and thirdly, whether the questions set in examinations adequately cover the newer parts of the syllabus.

Vernalization of Winter Rye during Ripening

VERNALIZATION of winter rye by chilling, which normally is carried out during the germination of ripe grain, has been successfully applied during ripening while the ears remained attached to the parent plant. To this end each ear was placed in a boiling tube inserted in the neck of a vacuum flask containing ice. Thus the ear was not in direct contact with the ice and a fairly even temperature of 1°–1·5° C. was maintained within the tube. The ears were selected for treatment at various times after anthesis, and, after being kept for twenty-four days at a low temperature, allowed to finish ripening normally. Ears which were selected from the middle period of ripening alone produced grain which on spring planting proved to be vernalized. The control grain came from ears kept for a similar period in vacuum flasks without ice.

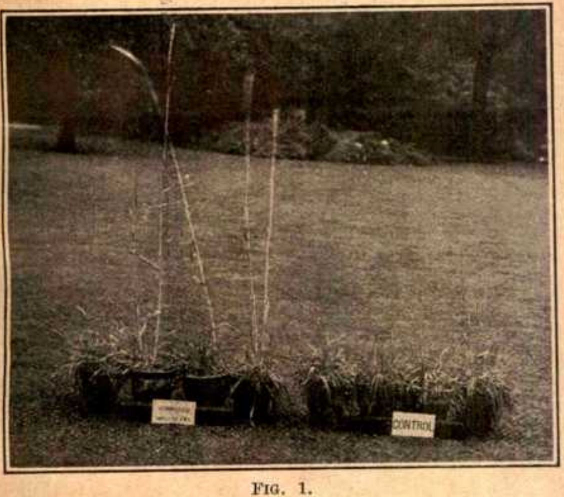

FIG. 1.

Ripening ears with stems and green leaves were also successfully vernalized after being detached from the plant. They were placed in water, and chilling carried out in a refrigerator at 1° C. for a period of six weeks. Control ears were ripened in a dark room at 17°–18° C. A photograph of plants grown from grain of chilled and unchilled ears is shown (Fig. 1).

Experiments are now in progress to find at which stage in the development of the embryo the application of cold is most effective.

Sparking Potential of Mercury Vapour

THE sparking potential of mercury vapour between parallel electrodes previously degassed at about 750° C. has recently been measured in this laboratory throughout a large range of vapour densities, and the influence of the material of the cathode on the sparking potential has also been examined.

When the density of the vapour is expressed in terms of the corresponding pressure, p mm. of mercury, of a permanent gas at 17° C., and d is the distance in cm. between the electrodes, the sparking potential was found to be almost a linear function of the spark parameter pd from about 500 to 5,000 volts. The value of pd at the minimum sparking potential was 1, while at the highest vapour density used pd was 85 and the sparking potential was 5,000 volts.

The minimum sparking potential V_m was measured for a number of different cathode surfaces, and the values obtained are given in the accompanying table, where φ is, approximately, the work function of the cathode.

Cathode.	φ	V_m in volts.
Clean nickel	5	400
Clean 'Staybrite' steel	4·7	380
Nickel coated with a mercury film	4·4	305
Steel " " " "	4·4	305

It is seen that large changes in the value of V_m were produced by small changes in the work function of the cathode surface.

A corresponding variation of the normal cathode fall with the work function of the cathode material has previously been noted[1]. With the highest values of pd, however, the sparking potential was practically independent of the nature of the cathode surface, and this result is in accordance with the general theory of the spark discharge[2]. At these high vapour densities, also, the spark time lag was very pronounced.

The large variation of V_m with the nature of the cathode surface affords strong evidence in support of the view that the cathode plays an important part as a source of electrons under the impact of positive ions; and that in mercury vapour this mechanism is of predominating importance in the production of the spark and in the maintenance of the discharge. In this respect mercury vapour differs from a typical diatomic gas like hydrogen[3]. However, this result does not necessarily exclude the possibility of the existence of the process of ionization by positive ions in collision with the molecules of mercury vapour which in fact has been detected[4] with ions of energies of about 700 electron volts, but it would appear that this process does not predominate over the electrode effect, especially at those densities which correspond to the minimum sparking potential.

Auroral Phenomena and the Behaviour of the Ionosphere during a Total Solar Eclipse

FROM the appearance of very long auroral rays in the middle of the night, as described for the auroral display at Oslo of October 16 [see NATURE, Nov. 28, p. 930], it follows that the density of matter also during the night may decrease very slowly upwards.

This state is essentially due to the large number of free electrons present. On account of the high mobility of the electrons, the coronal structure of the upper atmosphere[1] produced on the day side will spread (diffuse) into the night region. This spreading process will counteract the night contraction and support the maintenance of 'a coronal distribution' on the night side of the earth.

In this way we may also account for the fact, shown by radio-echo measurements, that the reflecting layers maintain their conductivity and reflecting power during a total solar eclipse[2].

Thus the distribution of matter and the corresponding electrical state on the night side of the upper atmosphere which is revealed by auroral investigations enable us to understand certain essential features regarding the behaviour of the ionosphere during a total solar eclipse.

The spreading or diffusion process essentially effected by free electrons has also to be taken into account in any estimate of the rate of recombination from changes of ion concentration derived from radio-echo measurements.

Demonstration of Phosphorescence

THIS letter describes an interesting lecture experiment in connexion with phosphorescence. It provides a striking demonstration with apparatus of a simple character, and makes available a 'permanent' source of 'cold' light.

It is well known that most, if not all, materials that phosphoresce as a result of exposure to light are also fluorescent. This fact, coupled with the initial rapid decay of phosphorescence characteristic of phosphors, renders it difficult to appreciate visually the extent to which phosphorescence may be excited. Luminescent powders are commercially available which exhibit marked phosphorescence when illuminated by wave-lengths of three thousand to four thousand Ångström units, and the modern electric discharge lamp, in which a discharge passes through mercury vapour at approximately atmospheric pressure, provides a convenient source of these wave-lengths.

Phosphorescence resulting from irradiating the selected powder can be observed at a constant value, if it is continually re-excited and viewed for a short period while the radiation is discontinued. If it is observed immediately after irradiation, then the phosphorescence will have suffered little decay and will be near a maximum.

This effect can be secured very conveniently by rotating an opaque cylinder coated with phosphorescent material in front of a lamp radiating suitable wave-lengths. The side of the cylinder remote from the lamp is then a source of 'cold' light of quite high brilliancy.

The apparatus that has been constructed is illustrated in Fig. 1, and it consists of a Mercra 400 watt lamp provided with a special outer bulb functioning as a filter to pass only ultra-violet radiation between 3,000 A. and 4,000 A. Chances No. 14 is a good example of a suitable filter. The cylinder may be rotated at various speeds and may have a surface brightness of 10 equivalent foot-candles, and a total luminous output equivalent to that of a 1–1/2 watt tungsten filament lamp. In this connexion it is of interest to note that a road surface with a brightness of 0·5 equivalent foot-candles is considered to be illuminated to a fairly high standard, and one once again realizes the attractiveness of the (at present) impracticable suggestion to employ phosphorescent materials, excited during the daytime, on our road surfaces or surroundings.

Diamagnetism of Mixtures of Organic Liquids

CERTAIN measurements of the magnetic susceptibility of binary mixtures of organic liquids made by us[1], which are at variance with the determinations of several investigators and which we have agreed are in error for reasons stated[2], are still being quoted in text-books and the literature.

We have now completed the remeasurement of the susceptibility of the binary mixtures under discussion, namely, acetone-chloroform, acetone-trichloroethylene, chloroform-ether, by the Gouy method[3] and find that the deviations of these mixtures from the mixture law do not exceed 2–3 per cent except in the case of acetone-chloroform, where a maximum deviation of about 4 per cent is obtained: results which are substantially in agreement with those of our critics.

Since our new apparatus came into use, full details have been published for the mixtures of acetone and trichloroethylene[4]. Details of other binary mixtures of organic liquids are to be found in the same paper and in a further paper[5]. The general conclusions to be drawn from the values obtained for about fifteen series of binary organic mixtures of substances of varying chemical type are that, in common with other physical properties, (i) the magnetic susceptibility exhibits slight deviations from the mixture law for most binary mixtures of organic substances; (ii) where the constitution and molecular weight of the constituents of the mixtures are similar the deviations are very small, rarely exceeding 0·5 per cent; and (iii) where there is considerable difference in chemical constitution or mass the deviations are slightly larger, about 1–4 per cent. When, however, molecular susceptibilities are compared, the deviations are much smaller, rarely exceeding 0·1 per cent, and thus come into line with the deviations of other physical properties from the mixture law.

Centrifuging in Rotating Hollow Cylinders

PROBLEMS in particle size analysis in disperse systems may be divided in general into two classes, namely, those involving the determination of the size or molecular weight of particles comprising the disperse phase of a monodisperse system, and those involving the determination of the particle size distribution function for the disperse phase of a polydisperse system.

Dr. M Schlesinger has described[1] a most ingenious method for determining the molecular weight of units of the disperse phase in presumably monodisperse systems. The method employs the Sharples super-centrifuge run with a 'closed bowl'. Using the Sharples super-centrifuge with a continuous flow or separator bowl, we have been able to obtain sufficient data for the calculation of the particle size distribution curve in such polydisperse systems as colloidal clays, all particles of which have equivalent spherical diameters substantially below 500 mμ.

Our method, which was presented before the thirteenth Annual Colloid Symposium in St. Louis, on June 11, 1936, involves feeding at a constant rate a suspension of known concentration and temperature into the centrifuge bowl, which rotates at constant speed. As the suspension flows through the bowl, there is a partial sedimentation of the particles of the disperse phase on to a removable celluloid liner flush with the walls of the bowl. After a suitable amount of suspension has flowed through the bowl, the operation is discontinued and the liner containing the sediment withdrawn. At definite distances along the liner, the sediment is quantitatively removed and weighed. From this data the particle size distribution curve may be calculated. As it is unnecessary to settle out the disperse phase completely, the effluent liquid, while reduced in concentration in disperse phase, may still contain some disperse phase, depending on the rate at which the suspension is fed into the bowl during the run.

This method, which will be published in detail in the volume reporting papers at the 1936 Colloid Symposium, as well as in a forthcoming issue of the *Journal of Physical Chemistry*, is particularly useful when it is desired to make a particle size fractionation of some polydisperse system; for example, when it is contemplated studying the influence of the particle size variable upon other properties of the colloidal sol. We have developed it in particular for use in determining the influence of particle size on thixotropy and rheopexy of suspensions of the colloidal clay bentonite.

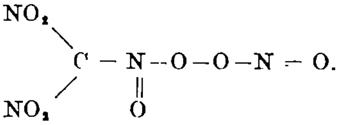
Constitution of Tetranitromethane

IN a "Research Item" in NATURE of November 7, p. 807, attention is directed to the question of the constitution of tetranitromethane. Instead of the usual symmetrical formula, it is suggested that the substance is to be represented by the expression:



$$(\mathrm{NO_2})_2\mathrm{C}-\underset{\underset{\textstyle\mathrm{O}}{\|}}{\mathrm{N}}-\mathrm{O}-\mathrm{O}-\mathrm{N}=\mathrm{O}.$$

The arguments[1] have been reproduced so recently in NATURE that it is unnecessary to repeat them, but they appear to be fallacious for the following reasons: It is said that the symmetrical formula does not explain the oxidizing properties of the substance, but this statement fails to take into account the strong inductive effect of the nitroxyl groups. The molecule as a whole must be powerfully cationoid and electron-accepting, as indeed is shown by the colorations produced when tetranitromethane is dissolved in anionoid solvents without decomposition. But furthermore, the $C(NO_2)_3$ group must be that substituted methyl group with the greatest general electrical effect (electron-attracting) and it will excel in this respect even the groups CF_3 and CCl_3. It is therefore not at all surprising that the compound $C(NO_2)_3.NO_2$ simulates peroxidic character and is very readily reduced.

A perfectly analogous case is that of carbon tetraiodide, which is very readily reduced to iodoform, and in this case a special constitution would be difficult to devise. Again, it is said that one of the nitro groups of tetranitromethane is markedly different from the others in its reactions, but it should be remembered that when this first nitro group has been removed, the substance is no longer tetranitromethane. It has acquired the hydrogen atom necessary for transition into the *iso*nitro form. The final and conclusive argument in favour of the formula $C(NO_2)_4$ and against the proposed revision is provided by the fact that tetranitromethane has a very small dipole moment[2].

Nicotine Inhibition of Oxidation and Fermentation

IN a recent letter to NATURE[1], I have reported some observations on the more powerful inhibition of various oxidations in micro-organisms by *dl*-nicotine as compared with the *l*-form. Such results are regularly obtained when *dl*-nicotine prepared according to the method of Pictet and Rotschy is used; this preparation is relatively more efficient than the natural form. But optically pure *d*-nicotine later prepared by us lacked these properties. It was therefore concluded that some active principle always present in the racemic preparation is responsible for the observed effect. This principle has been isolated and identified as hydronicotine. Further, when we hydrogenized nicotine in two different ways and tested these preparations, we actually observed much stronger inhibition of oxidation in micro-organisms, as compared with nicotine, but no specific effect on fermentation processes. It is therefore concluded that hydronicotine and not the *d*-form is responsible for the biological effects described in my previous communication. Investigations along this line are in progress.

Points from Foregoing Letters

To explain the mechanism of certain thermal reactions in gaseous organic compounds, Prof. M. W. Travers assumes a series of transformations: molecules → activated state → complex → unstable intermediates → paired products, and states that the rate of reaction usually measured is determined by the transformation complex → unstable intermediates. He discusses the thermal decomposition of ethane and of ethane-ethylene-hydrogen equilibrium mixtures, and refers to the thermal decomposition of acetaldehyde, methyl nitrite and methylamine.

From the interchangeability of lactic dehydrogenase from heart muscle with alcohol dehydrogenase from yeast, in reactions involving reduction of pyruvic to lactic acid and of acetaldehyde to alcohol *in the presence of co-zymase*, E. Adler, Prof. H. v. Euler and H. Hellstrom conclude that co-zymase is the active co-enzyme for both those specific oxidation-reduction agents.

From an examination of the cast of the Taungs ape in the British Museum (Natural History) and of the photographs of the skull and diagrams of the teeth of the Sterckfontein ape recently described by Dr. R. Broom, Dr. E. Schwarz concludes that the animals to which they belonged were not in the direct ancestral line of man but were more nearly related to the gorilla.

Preliminary results of an investigation into the nature of the protein by Dr. Geo. Pincus in the enamel of teeth indicate that it contains no sulphur, though it has hitherto been believed to be a keratin. Its X-ray picture also differs from that of some keratins, and it appears to contain tyrosin.

Graphs showing temperature gradients in the north basin of Windermere during calm and in windy weather, in spring and summer, are submitted by P. Ullyott and P. Holmes. Unlike the conditions described by other investigators for lakes in the temperate zone, the authors find no *permanent* region of sharp temperature change (thermocline) separating an upper warm layer from a lower cool one; they find the thermocline only during windy weather, and then it may occur at any depth down to 15 metres.

Following an inquiry into the split-drill method of testing cereal varieties applied to data obtained by Wiebe on the yields of wheat, Barbacki and Fisher concluded that "the arrangements randomizing either pairs or sandwiches of half-drill strips give smaller errors than the systematic arrangement" advocated by "Student". Commenting upon this, "Student" considers the criticism unwarranted and states that although Barbacki and Fisher's arrangement is a fair example of half-drill experiment, their method of calculating the error was one which he had expressly rejected in 1923.

A group of leading workers in experimental biology discusses the teaching of genetics in the universities, and advocates greater co-ordination of genetics and cytology on the botanical and zoological sides than at present exists.

Prof. F. G. Gregory and O. N. Purvis report that they have successfully 'vernalized' winter rye by keeping the ears of the rye at a low temperature (1°–1·5° C.) for twenty-four days during the ripening of the parent plants.

The sparking potential of mercury vapour is found by Dr. F. Llewellyn Jones and W. R. Galloway to be almost directly proportional to the 'spark parameter' (pressure × distance), over a wide range of vapour densities. The authors give the minimum sparking potential at different cathode surfaces (nickel and steel, clean and mercury coated) and discuss the process of formation of ions.

A simple apparatus for the demonstration of phosphorescence is described by H. Warren. It consists of a rotating cylinder coated with the phosphorescent substance and exposed on one side to exciting radiation.

As a correction to some of their previous findings, Prof. J. F. Spencer and Dr. V. C. G. Trew state that they have redetermined the magnetic susceptibilities of mixtures of acetone-chloroform, acetone-trichloroethylene, and chloroform ether and find that the maximum deviations from the mixture law is about 4 per cent.

Research Items

Origins of Speech and the Orang-Utan

DR. CORNELIUS J. CONNOLLY, professor of physical anthropology in the Catholic University of America, as the result of a study of the brains of fifty species of primates from the lemur to man in the primate brain collection of the Smithsonian Institution, Washington, D.C., claims to have found in the cerebral cortex of the orang-utan the first rudiments of the brain structures of speech (*J. Physical Anthrop.*, Oct. 1936). It is believed by neurologists that the associative process, which with the power of making articulate sounds constitutes the essential element in human speech, is centred in that part of the cerebral cortex known as Broca's area, found in both frontal lobes of the brain, and set off from the rest of the brain by well-marked depressions, the inferior frontal sulci. This area is now found to appear first among the primates in the orang. Absent in the gibbon, it is more emphatically marked in chimpanzee and gorilla. The sulcus subdividing the inferior frontal region, on the other hand, is exclusively and constantly human, never appearing in the anthropoids; but there is evidence of it in *Pithecanthropus* and Neanderthal man. It is possible that the exclusively human *V*-shaped area of the cortex enclosed by this sulcus may be that in which the association between sound and objects, making symbolism possible, takes place. So far as surface pattern of the cortex is concerned, the orang and two higher apes appear to have stopped on the threshold of speech. A second point emerges from the study of thirty-five orang brains of both sexes and various ages. This shows that while the principal sulci are present in all from birth and are standardized, there is greater variability in the pattern of the secondary channels in the orang than there is in either of the other great apes. As the sulci divide functional areas of the cortex, it would seem that the brain of the orang is possibly capable of further development.

Roding of the Woodcock

THE habit of the woodcock of flying over definite tracks at dusk and in the morning during the breeding season has been investigated by T. Warwick and V. D. van Someren (*Scot. Nat.*, 1936, p. 165). A particular pair of birds developed four roding circuits, varying in length from one to three miles and used with different frequencies. The flights, which took place irrespective of the kind of weather, lasted for almost an hour beginning about 9 p.m. and might include so many as thirteen circuits. Both birds occasionally flew together, but most often the male was unaccompanied. The rate of flight was approximately twenty miles an hour, and it was noticeable that as darkness fell the length of time taken to complete a particular circuit increased. The purpose of the roding habit is obscure: each circuit followed a line on which one or more marshy feeding places occurred, and when another woodcock was encountered the roding flight was interrupted while the interloper was driven off. The authors accordingly regard roding, since the woodcock is not a song-bird, as having an aggressive basis and as delimiting the territory by regular patrolling. It is unfortunate that the position of the nest relative to the system of roding flights was not definitely determined.

Resistance of Fish to Supercooling

EXPERIMENTS on the effect of low temperatures on live fish have so far shown that death follows cooling to about − 1° C. It was not clear whether death was due to the conversion of body fluids into a solid state, or whether the low temperature by itself had a fatal effect on living cells. To decide this question, P. J. Schmidt and his collaborators have investigated the result of keeping fish in supercooled water (*C.R. Acad. Sci., U.S.S.R.*, 3, No. 6; 1936). The authors succeeded in supercooling the body fluids, for a prolonged period, to a temperature more than 2° below their normal freezing point. The experiments proved that fish can stand supercooling even to − 3·06° C. if no crystallization of the surrounding water or of the body fluid occurs. This suggests that fish perish mainly from the effects of ice forming within the body, and not from the effects of low temperature. Such powers of resistance to supercooling should be of biological significance for fishes, since cases of supercooling of water occur in natural conditions. The phenomenon can be interpreted as a true anabiosis, if the latter is defined as a depression of life by the elimination of water from living matter, so that a complete cessation of life-processes results.

Standard Errors of Mendelian Ratios

TABLES of standard errors of Mendelian ratios have been worked out by Messrs. S. S. Purewal and P. K. Rao (Misc. Bull. No. 11, Imperial Council of Agric. Research, 1936. Delhi: Manager of Publications; London: High Commissioner for India. 12 annas or 1*s.* 3*d.*) The standard errors expressed in numbers of individuals have been prepared for the ratios 1 : 1, 3 : 1, 9 : 7, 15 : 1, 13 : 3, 27 : 37 and 63 : 1, and standard errors expressed in percentages for the 1 : 1 ratio. The tables give the standard errors for values of *n* from 5 to 1,000 and can be used for numbers up to 100,000. A deviation greater than twice the standard error is considered significant. These tables should be useful for geneticists and plant breeders.

The Temperature Scale

WHILE the final standard scale of temperature is Kelvin's thermodynamic scale, independent of the properties of any particular substance, it is on the properties of gases that we have to depend for the practical realization of the scale in certain low and certain high temperature ranges. An examination of the properties of hydrogen, nitrogen and carbonic acid then available led Daniel Berthelot in 1907 to conclude that the coefficients of expansion and of pressure of a perfect gas and of actual gases at very small densities were 0·0036618, from which it follows that the temperature of freezing water on the Kelvin scale is 273·09° K. Much accurate work on helium and the above gases has been done in the last thirty years, and from a consideration of it Prof. Keesom and Dr. W. Tuyn, in a communication from the Kamerlingh Laboratory of Leyden (Supplement No. 78), come to the conclusion that a more accurate value of the coefficient is 0·0036611, from which it follows that the freezing point of water is 273·14° K.

Velocity of Radio Waves

MOST of the measurements being made at the present time on the ionosphere are based on the assumption that radio waves travel with the velocity of light. The paper by R. C. Colwell, N. L. Hall and L. R. Hill, which appears in the *Journal of the Franklin Institute* of November, on the experimental determination of the velocity of radio waves, is therefore a timely one. The experiments were made between West Virginia University and Fairmont State College, which are 20 kilometres apart. A continuous train of very short radio pulses from the sending station travel to a receiving station, where their phase is adjusted so that a pulse starts back the instant it is received. Synchronization between the transmitting and sending station is automatically obtained, as they are both supplied from the same 60-cycle power network. The observations so far obtained indicate that the velocity of the ground waves varies between one half and two thirds the velocity of light. The experiments give no indication of the velocity of sky waves. To obtain measurements of these, it would have been necessary to have a second radio station on a stratosphere balloon. It is concluded that the velocity with which radio waves travel along the ground is considerably less than that of light. This reduction in the velocity is attributed to the influence of the conductivity and dielectric constant of the earth and to the ionization of a certain layer of the atmosphere. The authors also conclude that the velocity of ground waves is not constant, and that the strength of ground waves varies during periods of atmospheric disturbance. On one occasion, the received signal was four times normal strength, and during this period the measured velocity was a minimum.

'Lumophor' Glass for Tubes containing Luminous Gases

RECENT researches on 'lumophor' glass, that is, glass for use in making the tubes containing luminous gases, has led to the discovery of much more effective materials for making these tubes. A brochure recently published by Glaswerk Gust. Fischer, Ilmenau, Thuringia, gives many technical calculations and measurements on the efficiency of various types of lumophor glasses. An abstract of it is given in the November number of *Helios*, the electrical export trade journal published in Leipzig. It is found that the brightness of the tube increases very appreciably with the current taken by it, but the luminosity in lumens per watt shows its maximum value with a small tube current. The characteristics shown by the various types of lumophor glasses are all of a similar nature. Interesting data are given on the influence of external temperatures from − 60° to + 220° C. on the light intensity. It is known that luminous tubes for blue light burn differently according to the external temperature even when filled with a mixture of rarefied gases having high resistance powers against cold. This dependence is more pronounced when lumophor glasses are used. In this case, the luminous colour results from the radiation from the mercury vapour and the radiation of the luminescence of the glass walls. The experiments made with a photo-cell and the measurements show that the light intensity throughout the medium temperature range, which coincides with the surface temperature range, has the maximum value. At temperatures exceeding 220° C., No. 1 lumophor glass loses its pure white colour and assumes a greyish-white tint. At 0° C. the colour becomes duller as the pressure of the mercury vapour decreases. The light blue tube No. 2 shows a violet colour at − 40° and above 135° becomes a greyish-white. Owing to 'fatigue' of the glass, the light emitted falls 30 per cent in the first two hours and then remains constant, even after the lapse of 3,400 hours. Switching the tubes off invariably leads, on relighting, to an increase in luminescence.

A Co-ordinated Cuprous Complex

IN the most stable derivatives of cuprous copper, the co-ordination number appears to be 4, for example, in $K_3[Cu(CN)_4]$. It is found (F. G. Mann, D. Purdie and A. F. Wells, *J. Chem. Soc.*, 1503 ; 1936) that cuprous and silver iodides form compounds with tertiary phosphines and arsines analogous to the well-known non-ionic aurous chloride derivatives $[R_3P(As) \rightarrow AuCl]$. The cuprous compound would be expected (for 4-co-ordinate copper) to be $[(PR_3)_3CuI]$, analogous with $K_3[CuI_4]$. In this compound the copper is joined by three co-ordinate and one covalent link, giving the 7 electrons which the copper requires to attain the electronic structure of krypton. This suggests that the 2-co-ordination compound, $[R_3P \rightarrow CuI]$, should be very unstable, whilst actually many members of the phosphine and arsine series are very stable. X-ray analysis of the arsine compound shows that the true molecule actually consists of four simple units, $[Et_3As \rightarrow CuI]_4$. In this molecule, the four cuprous atoms are arranged at the apices of a regular tetrahedron: the four iodine atoms lie each at the centre, but above the plane of, one face of the tetrahedron. Beyond each cuprous atom is an arsenic atom lying on the elongation of the axis joining the centre of the tetrahedron to the copper: the three ethyl groups are then joined to each arsenic atom so that the tetrahedral angle is subtended both at the arsenic and at the first carbon atom of the ethyl groups. The stability is conferred by each iodine atom, in addition to being covalently linked to its original copper atom, also becoming joined by co-ordinate links to the other two copper atoms of the same tetrahedral face. Each copper atom acquires 7 electrons and is identical, in both co-ordination number and electronic structure, with that in $K_3[Cu(CN)_4]$. Interesting derivatives with αα'-dipyridyl were also prepared.

Orionid Meteors

MOHD A. R. KHAN, of the Osmania University, Hyderabad, Deccan, observed the Orionids from October 18 until 21, a total of 124 being recorded in the four nights. He has deduced a radiant at 93·7° + 14° by combining the observations over the period. It would have been better, if possible, to have used the results for each night separately, as the radiant moves eastward from night to night. Mr. J. P. M. Prentice discusses this matter in *Memoirs of the British Astronomical Association* (Report of the Meteor Section), May 1936. He concludes, after careful study of this shower, that the radiation comes from three sharply defined centres situated at close intervals in declination + 15°, and that these three centres move approximately 1·3° (small circle) each day.

Anniversary Meeting of the Royal Society

SIR WILLIAM BRAGG delivered his presidential address to the Royal Society on November 30, opening with the customary record of the losses by death of the Society during the past year. These have been unusually heavy, for they have included the Society's patron, H.M. King George V, two foreign members and no less than twenty-one fellows. Reference was made to recent gifts for research to the Universities of Oxford and Cambridge, and to the fact that the Society has undertaken a principal share in the administration of £200,000 bequeathed by the late Mr. H. B. Gordon Warren, the interest of which is to be applied to the encouragement of research in metallurgy, engineering, physics and chemistry. The capital value of the funds administered by the Society, including the Warren bequest and also the bequest of about £40,000 by the late Sir Joseph Petavel, is now approximately a million sterling. Surveying some developments of the past few years in the light of the research which has made them possible, Sir William said: "From this point of view the suggestion sometimes made that scientific workers might take a holiday looks more ridiculous than ever. No nation could afford such an intellectual disarmament in the face of the world; nor could the world itself in face of the evils that are to be overcome." There is the danger, however, that research funds may inadvertently lead a man into a blind alley so far as useful occupation is concerned; it should be the business of bodies administering such trusts to see that the highly qualified men they utilize are not wasted when their active research has ended. The address concluded with a discussion of recent developments in the field of the X-ray analysis of crystalline structure (see p. 953).

Sir William Bragg then presented the medals for 1936; extracts from his remarks are printed below.

PRESENTATION OF MEDALS

Copley Medal: Sir Arthur Evans, F.R.S.

Sir Arthur Evans is awarded the Copley Medal. He is the leading British authority in classical archæological studies: from his father he inherited a predilection for numismatics, a subject to which, in his earlier years, he made contributions of outstanding importance. His researches in Crete from 1893 onwards resulted in the discovery of the remains of a civilization which he named Minoan after the sea-king, Minos. He traced the development of the Minoan civilization from approximately 3200 to 1400 B.C., from the late Neolithic through the Bronze Age. His Cretan work, published in six volumes, "The Palace of Minos", has revolutionized our knowledge of the ancient history of the Near East.

Rumford Medal: Prof. E. G. Coker, F.R.S.

The Rumford Medal is awarded to Prof. Ernest George Coker, who has devoted a lifetime to the investigation of stresses in solids by means of polarized light. The original effect was discovered by Brewster in 1815, and Brewster himself suggested that the effect might be used for the direct exploration of stress. But although many physicists since Brewster's time investigated the effect, no one, until Coker came, developed a practical method enabling stresses in a model to be actually traced. Coker not only applied to such researches a material, celluloid, not hitherto employed, and capable of being cut to any shape, but he was also the first to devise a reliable instrument (the lateral extensometer) for measuring at any point the sum of the principal stresses, which is not directly given by the optical results. In many other ways, he made very important improvements in methods of observation, and he has, in fact, created a new technique and given the engineer a new instrument of discovery. His work is only now beginning to be recognized and taken up by the engineer.

Coker's first paper on this subject dates from 1910; since then he has published, either alone or with pupils and colleagues, some fifty or sixty papers, in which he has applied the method to almost every important engineering problem which can be approximated to on two-dimensional lines. In the course of his work, not only has he cleared up a vast number of problems and difficulties, but he has also rendered a great service to applied mathematics, by demonstrating to the engineer the substantial accuracy of the results of the mathematical theory of elasticity.

Coker's work fulfils admirably the condition laid down for the Rumford Medal which says that the discoveries for which it is awarded should be such as "tend most to promote the good of mankind". The results obtained by photo-elasticity in such subjects as the stability of dams and the strength of aeroplane frameworks will certainly be the means of saving many lives. Moreover, Coker has created a world-wide school: to his inspiration is largely due the modern development of photo-elastic laboratories in Japan, the United States, Belgium, Switzerland and Russia.

A Royal Medal: Prof. R. H. Fowler, O.B.E., F.R.S.

A Royal Medal is awarded to Prof. Ralph Howard Fowler. His general theory of statistical mechanics, his later applications of it to the equilibrium of mixed crystals and to a theory of semi-conductors, are of outstanding importance. His paper on dense stellar matter contains the first working out of the properties of a degenerate electron gas, and those on the internal conversion of γ-rays and on thermionic emission and stray field emission of electrons from metals were fundamental. His work on the theory of the photo-electric effect, especially as a function of temperature, led to a rational means of analysing emission frequency curves, which enables one to determine the true threshold frequencies. His work on the quantum theory of energy exchange between gases and solids broke new ground. Further, he has made notable contributions to the theory of the photo-electric current in semi-conductors, and has made notable contributions in recent years by his adaptation of wave mechanics, as it has been developed, to the solution of problems actually under investigation by groups of experimentalists working in close association with him.

A Royal Medal: Prof. E. S. Goodrich, F.R.S.

A Royal Medal is awarded to Prof. Edwin Stephen Goodrich. He is distinguished for his long series of researches on the comparative anatomy, embryology and palæontology of invertebrates and vertebrates, which have thrown light on some of the most fundamental problems of animal morphology. His work on the excretory organs of annelids and of *Amphioxus* resulted in a new conception of the nephridia and their relation to the cœlom and cœlomoducts. His memoirs on scales of fishes and on the median and paired fins threw fresh light on the classification and phylogeny of fishes and on the evolution of the vertebrate skeleton. His contributions to our knowledge of the segmentation of the vertebrate head are recognized as of the first importance. His volume on cyclostomes and fishes in Ray Lankester's "Treatise on Zoology" and his more recent book, "Studies on the Structure and Development of Vertebrates", are masterly and original contributions to the subject of comparative anatomy. In the opinion of many he is the outstanding morphologist of our time.

Davy Medal: Prof. W. A. Bone, F.R.S.

The Davy Medal is awarded to Prof. William Arthur Bone, who has had a wide and varied experience in the main branches of chemical science. His early work on the alkyl substituted succinic acids and allied substances, which furnished a valuable chapter in synthetic organic chemistry, was speedily followed by more fundamental researches on the thermal decomposition of hydrocarbons and their oxidation products and by quantitative studies of hydrocarbon combustion. The evidence collected during these prolonged and systematic investigations, devised to include a great variety of experimental conditions of slow combustion and detonation, was overwhelmingly in favour of the hydroxylation theory of the combustion of hydrocarbons. His study of the direct union of carbon and hydrogen led to a synthesis of methane from its elements.

The closely related problem of flame movements in mixtures of burning or exploding gas has been submitted by him to exhaustive examination with improved methods, which made it possible to observe for the first time some striking characteristics of this phenomenon.

On the subject of catalysis, Prof. Bone's contributions are of especial interest and importance. Thus he has recently demonstrated by a variety of convincing experiments that carbonic oxide and oxygen will unite in the gaseous phase in the absence of moisture.

In collaboration with many colleagues and students, Bone has investigated the difficult problem of the chemistry of coal and has applied new physical and chemical methods of identifying the constituents of this complex material. The benzenoid constitution of coals of widely different geological ages and maturity was demonstrated by oxidation experiments which furnished a complete series of the polycarboxylic acids of benzene. In this field of chemical research, Bone will always be regarded as a pioneer.

Darwin Medal: Dr. E. J. Allen, F.R.S.

The Darwin Medal is awarded to Dr. Edgar James Allen, who for the past forty-two years has been director of the Laboratory of the Marine Biological Association at Plymouth.

Allen has made many notable additions to our knowledge of marine biology, dealing with such diverse subjects as the nervous system of the lobster, faunistic studies of estuarine and other areas, systematic work on the Polychæta, the genetics of *Gammarus*, and contributions to fishery science. He initiated exact work on the association of bottom faunas with the nature of the deposits and has published valuable papers on the artificial culture of phytoplankton, in which he was one of the earliest to obtain successful results. Many years ago he followed the chain of events leading from sunshine and inorganic constituents of sea-water, through phytoplankton and zooplankton to food fishes, making some of the first contributions to a subject which has since shown striking developments.

When the international fishery investigations began, Allen undertook the English share of the work, which was then based on laboratories at Plymouth and Lowestoft: after the Great War the Lowestoft laboratory branched off and became the Government centre for economic fisheries investigations. He has been closely associated with the International Council for the Exploration of the Sea from its earliest beginnings. The organization of the work on water pollution, carried out by the River Tees Survey Committee, owes much to his initiative, and he is a member of the Committee dealing with similar problems in the River Mersey.

Much of Allen's work has been directed to the study of evolution The Hooker lecture, which he delivered to the Linnean Society in 1929, deals with the origin of adaptations, and his presidential address to Section D (Zoology) of the British Association in 1922 is again concerned with the evolution of life in the sea.

Throughout his long term of office at Plymouth, Allen has been the inspiration of the workers at the Laboratory, and the success of his labours is shown by the high quality of the research which has been carried out under his direction.

Hughes Medal: Dr. W. Schottky

The Hughes Medal is awarded to Dr. Walter Schottky of the Central Laboratory of Siemens and Halske, Berlin. He is best known by his contributions to the fundamental theory of thermionic emission. One of his investigations led in 1914 to the formulation of a theory of the effect of an electric field at the surface of a hot conductor upon the emission of electrons; another led to the discovery of the "Schrot" effect, which attributes certain variations in a thermionic discharge to random emission of individual electrons. He also discovered the so-called 'temperature effect' in ordinary conductors of electricity, which he traced to the thermal agitation of the molecules. Further, he made valuable contributions to the theory of space charge in vacuum tubes in the early days of the subject.

Apart from these mathematical contributions to our knowledge of principles, Schottky has added very greatly to engineering progress in wireless telegraphy. In particular, he invented the screening grid valve which has everywhere superseded the triode valve in the high-frequency amplifiers employed in receiving broadcast signals. He is also the inventor of the method of super-heterodyne reception wherein the currents of intermediate frequency are amplified. These are two of the most important wireless inventions of the past twenty years.

The Indian Institute of Science

QUINQUENNIAL REVIEWING COMMITTEE

THE report of the second quinquennial reviewing committee of the Indian Institute of Science, Bangalore, presented to the secretary of the Government of India toward the end of March last, has now been published (Bangalore : Mysore Residency Press). The committee was appointed by H.E. the Viceroy of India two months earlier, and its members were : Sir James Irvine, principal and vice-chancellor, University of St. Andrews (chairman) ; the late Dr. A. H. Mackenzie, pro-vice-chancellor, Osmania University, Hyderabad ; and Dr. S. S. Bhatnagar, professor of chemistry in the Punjab University, with Mr. F. F. C. Edmonds, inspector of schools, Coorg and Bangalore (secretary).

The terms of reference to the Committee were :

"To review the working of the Institute with special reference to the purposes for which it was founded and, if any changes are considered desirable in the organization or activities of the Institute for the better achievement of these purposes, to make recommendations accordingly, but with due regard to the Institute's actual or reasonably augmentable financial resources."

The subjoined extracts are from the report of the Committee :

We have felt compelled to consider the whole question of the aims and objects of the Institute as, during a period of unusually rapid change, it is more than ever necessary to secure that the policy pursued is consistent with the wishes of the Founder and of the contributing bodies. We may at once express the view that, as a first consideration, the province and purpose of the Institute must be defined in more precise terms than at present, and that such a definition should be adopted officially both by the Council of the Institute and by the Government of India. Only in this way can the aims and objects of the Institute be placed beyond individual and fluctuating interpretations ; in the absence of such definition, no continuous policy can be developed.

It may be admitted that the purposes for which the Institute was created have never been clearly defined, but this is in no sense a reflection on those who founded it or who have since administered its affairs. The Founder, the late Mr. J. N. Tata, was a public-spirited and enlightened benefactor who initially envisaged a scheme for creating an Imperial Teaching University the activities of which were to be focused in three main departments, viz., a Scientific and Technical Department, a Medical Department, and a Philosophical and Educational Department. Even with the generous support offered by Mr. Tata, so comprehensive a project was beyond realization, and the idea eventually took shape that the new foundation should be a Research Institute rather than a University.

Later the Government of India, with the concurrence of the heirs and executors of Mr. J. N. Tata, defined the Scheme for the Administration of the Institute as follows :

"The object of the Institute shall be to establish Chairs and Lectureships in Science and Arts especially with a view to the promotion of original investigations in all branches of knowledge and their utilization for the benefit of India, and to provide and to assist in the provision of suitable libraries, laboratories, and all necessary appliances."

No doubt with the laudable intention of securing a measure of elasticity and reasonable freedom to meet changing conditions, the above statement of purposes was drawn up in general terms, but nevertheless the intention is clearly revealed. According to the scheme as approved, the main objective of the Institute is to promote original scientific investigations and to facilitate the utilization of knowledge "for the benefit of India". Professorships and lectureships, offices traditionally associated with University teaching, are certainly envisaged, but in this case these offices are provided for a specific purpose, viz., the equipping of students for research.

In our opinion, the phrase "the benefit of India" strikes the keynote of the policy to be followed by the Institute. Admittedly there are many ways in which a research institution may operate for the benefit of a country and it is owing to the varying interpretations placed on this critical phrase that differences of opinion have since arisen. It may be argued with good reason that the prosecution in India of research of high merit is a benefit to the country through the prestige it confers ; similarly the provision of a steady succession of young men whose minds have been developed through the discipline of research in pure science is another result which comes within the compass of the phrase "the benefit of India". But, whilst in full agreement with such arguments, we believe that the initial conception of the founder was that the activities of the Institute should be devoted primarily to securing for India the material benefits expected to follow from the close association of scientific research with the industries of the country.

We are fully alive to the advantages and the cultural and material benefits which accrue from fundamental scientific work ; equally we recognize that there is no conflict between pure and applied research which can be, and ought to be, prosecuted side by side to their mutual advantage. We are chiefly concerned with the problem as to which of these complementary activities should carry the greater emphasis, and we hold strongly the opinion that, in accordance with the wishes of the Founder, this emphasis should be laid on the applications of scientific research to industry. Accordingly, our first recommendation is that Clause 3 in the Regulations be amended to read as follows :

"The object of the Institute shall be to establish Chairs in Science and Arts for the purpose of providing advanced instruction and conducting original investigations in all branches of knowledge and particularly in such branches of knowledge as are likely to promote the material and industrial welfare of India ; to provide suitable libraries, laboratories, and equipment ; and to co-operate as far as possible with such recognized institutions as exist or are founded in future for cognate objects in India."

The adoption of the above regulation will remove ambiguity as to the purposes of the Institute, will enable a continuous policy to be followed, and will inspire confidence in the bodies which assist its finances. As will appear later in this Report, we do not recommend the curtailment of fundamental scientific research or the abolition of teaching; but in terms of the regulation now proposed, teaching (except in the case of electrical technology which stands in a special position) should be confined to preparing workers as investigators, and, while research in pure science should continue to be an approved purpose, the major part of the resources of the Institute should be applied to those investigations which are likely to be of direct benefit to industry in India.

The evidence before us shows that in some quarters it is tacitly assumed that the Institute should be capable of searching for and selecting industrial problems, of solving these problems in the laboratory, and finally of applying the results on a technical scale. Such an attitude of mind is by no means confined to India, and so long as it is maintained, the Institute will remain the target of uninformed criticism. It must be remembered that, judged by the standards of modern research organizations in Europe and America, the Institute is small and has to work within a comparatively narrow income. But even the largest and best endowed research organizations can provide only a limited service to industry, in the sense that while they may succeed in winning the new knowledge necessary to solve an industrial problem, they are rarely capable of translating laboratory results into terms of technical practice. Different types of mind and experience as well as different equipment are necessary to bridge the gap between theory and practice. In short, the correlation of science and industry demands, as a rule, three types of men, viz., (a) those who find the problem, (b) those who unfold the new knowledge necessary to solve it, and (c) those who apply the results. The corresponding qualities and knowledge are rarely combined in the same types of individual or in the same institution.

Taking into account the restrictions imposed on the Institute by its size, its income, and its geographical situation, it is essential to relieve the staff of the sole responsibility for finding industrial problems for investigation. These problems should be submitted to the Institute by some responsible body capable of collecting proposals from India as a whole, and of sifting them so as to exclude merely routine inquiries (for which other agencies are available) and suggestions which are too unwieldy to be handled by the comparatively small number of workers available at Bangalore. The initiation of problems might well be undertaken by such bodies as—

The Industrial Intelligence and Research Bureau,
The Imperial Council of Agricultural Research, and
Departments of Industries.

Co-operation with bodies such as those mentioned above will enable the Institute to keep in constant touch with the industrial needs of India.

Suggestions for research initiated in the above way would be received in the ordinary course of business by the Registrar and would be submitted by him to the Senate which, in turn, would allocate the problem to the appropriate department or departments. In this way, each inquiry would receive the benefit of several expert opinions, a team spirit would be fostered, and the departments of the Institute would stand in less danger than at present of intellectual isolation. To make this proposal effective will demand something more than merely formal acquiescence on the part of all concerned. The active prosecution of applied research should be regarded as a duty, willingly undertaken with the certain knowledge that the more energetically this duty is fulfilled, the less scientific prominence becomes attached to the workers themselves. Few publications are likely to result from such research work, but this need not be deplored if in the end the Institute is made to play the part for which it was created. Above all, it will be necessary to develop in members of the Institute the idea that there is no loss of scientific dignity in directing scientific research to the service of man.

CONCLUSION

Throughout our inquiry and in compiling our Report we have been actuated by more than a desire to rectify an unhappy situation. It has been our earnest endeavour to make suggestions, conceived in a spirit of impartiality, which may help the Institute to attain a position where, without challenge, it will operate for "the benefit of India". Within the framework of our scheme and free from the distractions of routine administration, the Director may devote his full powers to fundamental researches in Physics which must redound to the fame of the Institute as a home of intellectual effort. Equally, the Professors in other departments are placed in a position which will enable them to bring their best energies to bear on research problems affecting the industrial welfare of India, and to equipping students to play their part in the application of such work. With improved status, a greater security of tenure, and a clearer prescription of their duty, there is every reason to believe that the Professors will render this service in a happier and more helpful atmosphere.

As we foresee the effect of our proposals, the Institute in the future may be regarded as divisible into three sections each with its special sphere of activity, viz., (a) Physical and Mathematical Sciences in which the research work will continue to be primarily of a fundamental nature with an allegiance to the intellectual rather than to the industrial aspects of life, (b) Chemical Sciences which will be called upon to carry the main responsibility for applied research while not neglecting original work of a more academic type, and (c) Engineering Sciences where the duties for the time being will be in part instructional and in part investigatory. We have suggested that these sections be granted a reasonable measure of autonomy, but they will not be isolated units, for they will find a common meeting place in the reconstituted Senate, where their efforts to serve science and to serve India will become in the best sense co-operative.

It may be the case that our proposals are a compromise, forced upon us by circumstances, but nevertheless we believe that they represent a workable solution of existing difficulties. If given a fair trial and if operated in the right spirit, they will enable the Institute to begin its second semi-Jubilee period with renewed hope. If our scheme fails, it can only be through the clash of personalities beyond the remedy of any powers possessed by a Reviewing Committee. Some of our proposals are far-reaching in their effect. Their full significance will be apparent only by a study of the complete text of our Report.

Educational Topics and Events

BIRMINGHAM.—The Huxley Lecture is to be delivered on December 10 at 5.30 p.m. in the Medical Theatre of the University, by Prof. A. M. Carr-Saunders, professor of social science in the University of Liverpool, who has chosen as his subject "The Population Problem in Great Britain".

CAMBRIDGE.—The Vice-Chancellor gives notice that the professorship of animal pathology is vacant by the resignation of Prof. J. B. Buxton. A meeting of the electors will be held on January 19. The Council of the Senate has determined that at this election preference shall be given to a candidate whose experience and interests lie chiefly in scientific investigation rather than in veterinary practice, and that a professional veterinary qualification, though undoubtedly advantageous, shall not be regarded as essential.

EDUCATIONAL films have been produced in such numbers and variety and are in such wide demand as to justify the publication by the Central Information Bureau for Educational Films (103 Kingsway, London, W.C.2) of a "National Encyclopædia" and of bi-monthly bulletins, entitled *Film Progress*, for keeping it up to date. Bulletin No. 4, issued in September, reviews the work of the Bureau from 1932, the year in which it was formed. It published in the following year a "Guide", which was brought up to date and re-issued as the "National Encyclopædia" a year ago. Through the medium of *Film Progress* it keeps in touch with schools in all parts of the Empire and in many foreign countries, including China, Chile, Holland, Latvia, Rumania, the U.S.A., and the U.S.S.R. It has advocated the formation of a school and parents film society to aid in the installation of projectors in schools, an object which is also attainable through the formation of local branches of the British Film Institute. The current issue of *Film Progress* includes several reviews of books, descriptive lists of new films and detailed practical suggestions on how to train members of the school staff and selected students in the handling of projectors. Very many of the new films described appear to be admirably suited for inclusion in cinema entertainment programmes but for the supposed prejudice of cinema-goers against everything admittedly educational. Among them is "Citizens of the Future", a survey of public education claiming to show how the schools are fitting children to employ their leisure time in useful occupations and preparing them to take their proper place in a world demanding high standards.

PROFESSORS of "Things in General" are needed to cope with the undergraduate situation in American universities to-day. This is one of a number of interesting conclusions reached by Prof. H. G. Merriam of Montana in a recent address on "The Liberal Arts College in State-supported Universities". The ancient ideal of making a scholar and gentleman as the aim of a university education was long ago given up, but the idea of making scholars continues to influence university instruction. Now it is recognized that among the myriads that pass on from high school to college, very few have the stuff from which scholars can be made, and a vast amount of instruction, lacking the integrating power of a clearly defined goal, is a futile hodge-podge. The primary function of instruction during their first two years in college should be, in State-supported, if not in all institutions, to train the students for worthy citizenship. Real problems of the individual and of society must be dealt with realistically and frankly, even when this involves breaking away from the American tradition that a college professor should avoid themes of popular contemporary interest lest he should be quoted in newspapers. The youth of to-day are impatient of theory except as manifestly applicable to live issues. The content and technique of instruction must be based on a consideration of such questions as: "What does the individual need to know about the fundamentals of the good life; about what good reasoning is and what its value; about the uses of emotion and the control of it; about society, its composition and working; about what factors in politics can be and should be controlled?"; and developed in the light of the conception of education as a gradual slow lifting of the people of a democracy to as high a level of thinking and feeling as possible.

Science News a Century Ago

Electric Currents in Metalliferous Veins

WRITING from 4 Clarence Street, Penzance, on December 6, 1836, to William Sturgeon, W. J. Henwood, the Assay Master of Tin in the Duchy of Cornwall, dealt with the subject of "Electric Currents observed in some Metalliferous Veins". In his communication he described briefly the geology of Cornwall and the methods of making his experiments, discussed the results obtained, and examined the various theories which had been put forward to explain the phenomena. Experiments were made by pressing plates of sheet copper 12–20 inches long and 3–4 inches wide closely against such portions of the metallic contents of the veins as were thought proper for examination. Copper wires 0·05 inches in diameter were connected to the plates and to a galvanometer. In some cases, 600 feet of wire were required. Copper, pyrites, vitreous copper ore, black copper ore, galena and blende were among the contents of the veins, but it was only from the metallic parts of the veins that currents were obtained. Henwood had assisted Robert Were Fox in the first experiments of the kind made, and he had then extended them to mines in all parts of Cornwall (*Sturgeon's Annals*, 1, 124).

Graham's Work on the Constitution of Salts

AT a meeting of the Royal Society held on December 8, 1836, Frances Baily being in the chair, the second part of a paper by Thomas Graham was read. It was entitled "Inquiries respecting the Constitution of Salts of Oxalates, Nitrates, Phosphates, Sulphates and Chlorides". "In the third section," said the report on the paper, "he discusses the constitution of the phosphates. Phosphoric acid, he observes, is quite peculiar in being capable of combining with bases in three different proportions; forming besides the usual class of monobasic salts, containing one atom of acid to one atom of protoxide as base, two other anormal classes of salts, in which two or three atoms of base are united to one atom of acid, namely the pyrophosphates and the common phosphates, as they are usually denominated, but which the author proposes to designate by the terms *bibasic* and *tribasic* phosphates. Arsenic acid forms only one class of salts; but that class is anormal; every member of it containing three atoms of base to one atom of acid like the common, or tribasic, phosphates. These anormal classes of phosphates and arseniates are the only known salts to which the ordinary idea of a subsalt is truly applicable: all other reputed subsalts being probably neutral in composition, as has been shown by the author in the case of the subnitrate of copper; for they all bear an analogy to this salt in their small solubility and other properties, while they exhibit little resemblance to those classes of phosphates and arseniates which really possess more than one atom of base."

The Gresham Lecturers

On December 9, 1836, the Court of Common Council of the City of London considered a report which had been presented on the question of transferring the Gresham Lectures from the small incommodious room at the Royal Exchange to the City of London School. In its report of the proceedings, *The Times* said: "There are seven lecturers under the will of Sir Thomas Gresham, each of whom is paid a liberal salary for occasionally lecturing upon scientific and other topics, in an obscure apartment in the Royal Exchange, and the very spacious and commodious school endowed by the Corporation being almost finished, a committee was appointed to consider and report the best means of deriving some public advantage from the employment of the lecturers. The Corporation have been for some time endeavouring to obtain the consent of the gentlemen who derive the pecuniary emolument from these appointments to transfer their exertions to some more enlarged sphere of action in the city; but hitherto all attempts to induce them to leave the old station, whose walls have so long witnessed their abortive labours, have been ineffectual."

The lecturers, with one exception, objected, maintaining among other things that the removal of the lectures to the School "would not be advantageous to the public, but on the contrary would be injurious to the foundation of the Gresham institution, by attaching it to the school and destroying its independence". *The Times* of December 13 contained a letter from one of the lecturers and a copy of the resolutions passed by himself and the others on November 17. One of these ran "That, in the opinion of the lecturers, there can be no want of funds to maintain or carry out the Gresham lectures according to the founder's intentions, it appearing from the report of the Charity Commissioners of 1821 that the yearly income of the Gresham estates then amounted to £6,080, while the yearly payments, on account of the trusts, only amounted to £1,113 4s."

The Gresham professorships of "divynitye, astronomy, musicke, geometry, law, physicke and rethoricke" date from 1595, Henry Briggs being the first professor of geometry. From 1597 until 1768, the lectures were given in Gresham's house in Bishopsgate Street. They were then given in the Royal Exchange until that building was destroyed by fire in 1838. In 1843 a special building was erected in Gresham Street, this being replaced in 1913 by the present College. The chairs of geometry and astronomy are the oldest in Great Britain.

Norman Harris: Petrological study of the Portrush sill and its veins. The Portrush sill has been mapped on the 25-in. scale, particular attention being paid to variations within the sill itself, and to the different types of veins and their relationship with the hornfelsed lias of the roof. The bulk of the intrusion is coarsely mottled olivine-dolerite; then passes marginally into a fine-grained intergranular type. Micrometric analyses show that the proportion of olivine and iron-ore increases with depth. Chemically the average rock corresponds to the Hebridean Plateau-Magma-Type. Various types of hornfels and their mineral developments are described. Several occurrences have been found of veins of mobilized hornfels which pass downwards into the sill from the roof. Other veins and sheets within the sill are shown to comprise metasomatized hornfels and also a variety of synthetic rocks which are referred to the action of the magma and its emanations on included rafts of hornfels. The absence of veins in the Lias roof and the capacity of the hornfels to inject the olivine-dolerite indicate that the hornfels was under internal compression, presumably due to expansion, while the upper part of the sill was contracting and under internal tension. A later hydrothermal stage is represented by widely distributed calcite-chlorite-zeolite veins. Five types of pyroxene have been recognized in the rocks investigated. Analyses are given of two of the pyroxenes: common augite and pigeonite.

Paris

Academy of Sciences, November 9 (*C.R.*, 203, 901–960).

Alfred Lacroix: The meteorites (æroliths) found in the Tanezrouft (Western Sahara). The two fragments found appear to have fallen at the same time, very recently. From the mineralogical and chemical examination, these meteorites are pliosideriferous chondrites.

Armaments and the Scientific Worker

THE recently issued report* of the Royal Commission, which has dealt with the private manufacture and sale of munitions of war, contains a number of special points of particular interest to the scientific worker. A considerable amount of evidence was laid before the Commission designed to show that the manufacture of armaments should be concentrated in Government hands to promote the development of research, design and invention. It was argued that centralization of research work under unified control prevents dissipation of effort and that closer contact is possible between research and experimental work in Government stations, which have greater facilities than private establishments for experiment. Similarly, it was urged that money is more readily available for research in Government establishments, where there is not the necessity to visualize a prospect of dividend on capital that there is with private enterprise, as well as the danger of prejudicing the interests of the State if a private manufacturer does not develop a new invention which may not be to his own advantage, the motive of profit-making in certain circumstances tending to retard the development of new ideas.

Other evidence brought before the Commission denied that the development of research, design and invention in the matter of armaments would be facilitated by nationalization. It was stated that research work is cramped within Government departments, and that in peace time funds for research are more readily made available by private industry than by the Government. It was also argued that the supply of war material by Government establishments alone would result in sound but mediocre material because the atmosphere and conditions of Government service do not favour the development of new ideas. Moreover, since discovery, research and development of new ideas result from individual effort, they do not lend themselves to centralized organization, and Government employees do not seek to assume additional responsibilities or incur the risk of putting forward new ideas which may be regarded as impracticable in high quarters. Not only does competition under private manufacture provide a strong incentive to individuals to find new and improved devices, but also research conducted by commercial undertakings in non-military matters is just as likely to result in discoveries of military value, the tank itself being cited as an idea which emanated from a private engineering firm.

The report itself makes no pronouncement either upon the separate aspect of the case of the opponents of private manufacture based upon its alleged inefficiency and the lack of opportunity for fully developed research, or upon the counter arguments in this matter of the supporters of the present system. Neither side refers to the ethical questions of the participation of men of science in preparations for war or the possible formulation of a professional code of ethics which at the present time is seriously occupying the minds of scientific workers whose participation is essential under either system of control. None the less, this is probably the most important aspect so far as the stimulation of invention and discovery is concerned.

Disgust and dissatisfaction at the prostitution of scientific effort to the elaboration of even more destructive weapons is now too widespread to be disregarded. Any system, whether national or international, which encourages unlimited misuse in this way can scarcely long escape repudiation and overthrow. While scientific workers are of no two minds as to the necessity for whatever armaments we must have being efficiently produced and maintained, they would find a very considerable support for opposition to any system which demanded their efforts in the development of offensive, as opposed to defensive, weapons indefinitely. Moreover, the scientific worker in matters of national defence should require no further stimulus than his specific occupation if those ethical needs are satisfied. If, on the other hand, they are left unsatisfied, it is doubtful whether any system of armaments manufacture can supply a stimulus as effective.

---

* Royal Commission on the Private Manufacture of and Trading in Arms (1935–36): Report. (Cmd. 5292.) Pp. 101. (London: H.M. Stationery Office, 1936.) 1s. 6d. net.

The report of the Royal Commission accordingly will be something of a disappointment to those scientific workers who are concerned with the ethical aspects of their participation in the preparations for national defence. It gives no lead on certain of these questions of research and development which, apart from the ethical aspect, are equally to be encountered in other fields of industrial and scientific research. At least, however, it emphasizes once more that the task of constructing world peace involves not merely the abolition of war, but also the far-reaching and impartial study of all its many causes, and not least that of the contribution and organization of the armaments industry itself.

Genetics and Race

IN the classificatory systems of a number of sciences the term 'race' occurs. Its meaning differs somewhat from science to science, but in all it has two main connotations, one being community of descent, the other distinctness from other races. Years ago the term signified something rather definite, but as time has passed and knowledge has advanced, this has given place to something much more vague. In general biology, for example, 'race' has now been largely abandoned in favour of 'sub-species'—a term much more in harmony with the concept that it is used to portray.

So long as the definition of race in the usage of one science does not invade the territory of another, it is a matter of no great importance if there are as many definitions as there are sciences; but if and when the term race as used by the physical anthropologists, for example, comes to have genetical implications, then it is reasonable for the geneticist to express the view that the anthropologists' definition must neither disregard nor offend genetic principles. This it does, for the anthropological use of the term dates from the time when it was believed that organic inheritance was of the blending variety, so that a mixed population would speedily approximate to a characteristic uniform type. This assumption has been shown to be incorrect by the establishment of the Mendelian basis of inheritance, and it is now known that constellations of characters necessarily become broken up and their ingredients shifted back and forth, combined and recombined, when, consequent upon the removal of isolation and inbreeding, crossing occurs. Furthermore, the assumption that man's evolution has taken the form of a separation into discrept isolated units is also incorrect, since migration and crossing have been operative for tens of thousands of years, so that, whereas the evolution of most animal types is divergent, that of man has been what may be called reticulate.

This was the reason for a joint meeting on September 11 of Sections H (Anthropology) and D (Zoology) of the British Association at Blackpool, at which the speakers were primarily concerning themselves with the question of whether or not the anthropologist's definition of race required modification in consequence of recent developments in genetics. But no one at this crowded meeting was unaware that the speakers were indirectly commenting upon the exploitation of the race concept by politicians who apparently are deliberately confusing linguistic terms such as 'Aryan', cultural terms such as 'germanic' and genetic terms like 'Nordic' by using them synonymously. It undoubtedly is the case that the term 'race' is now being used in a pseudo-scientific sense to further purely political interests, and this being so, it behoves all scientific workers—anthropologists, ethnologists and the rest—to respond to the demand on the part of the general public for guidance concerning the quality of the pronouncements of those who claim scientific endorsement for their own peculiar attitudes toward such matters as territorial readjustment, immigration quota or the relative intellectual pre-eminence of certain national groups.

The impression left at the end of this meeting was that the anthropologist's definition of race has genetical implications, that it has been established that the rise of modern genetics has necessitated a thorough overhaul of the basic concepts of physical anthropology, that the techniques of genetics should now be added to those of the anthropologist, and that genetical analyses of human differences and the correlation between them should be undertaken, and that, as applied to mankind, it is now quite impossible to give a scientific definition to the term 'race' since this has connotations which do not apply in human species. Now that the politician has appropriated the term, it is time for the man of science to relinquish it.

Sixty Years of Physical Science

Recollections and Reflections
By Sir J. J. Thomson. Pp. viii +451 +10 plates. (London: G. Bell and Sons, Ltd., 1936.) 18*s*. net.

IT is hard to believe that Sir Joseph Thomson will enter the ranks of the octogenarians on December 18—he has given, and is giving, so much to the world that it may very well happen to him as to Voltaire, who awoke one morning to find the world celebrating his eightieth birthday, he himself having scarcely had leisure to realize that he had reached middle-age.

Sir Joseph has seen many cities and many men; and, in the spirit of the Spanish proverb which says that "He who would bring back the wealth of the Indies must take that wealth with him", we should expect Sir Joseph's reflections on his voyagings in thought and in space to yield a rich harvest indeed.

Nor shall we be disappointed. The changes which he records are, in the total, almost incredible in their extent and variety. In that Palmerstonian world into which he was born, the University of Cambridge was still governed by those medieval statutes of the workings of which the late Dr. John Venn has left so vivid a picture. Memories of those days, when Hall was at 4, when water, of doubtful origin, was carried from pumps, and smallpox patients went through the various stages of their disease in bedrooms opening on a common staircase, still lingered on in that yet far-off Cambridge of 1876, when J. J. Thomson entered his name on the books of Trinity College. Sixty years have passed and the undergraduate of 1876, now Master of Trinity, has kept every term since then, and has been in residence for some part of every long vacation. Nor, as he remarks, can he remember any day during the last sixty years when his work has been interrupted by bad health. A remarkable record, and one which has probably been surpassed only by old Dr. Routh (1755–1854), the venerable President of Magdalen, who walked over Magdalen bridge, an undergraduate of fifteen years of age and thereafter left Oxford but once, on an abortive trip to France.

The Cambridge of 1876 was awakening to the importance of physical science. Maxwell had been appointed to the Cavendish chair in 1871 and the quadrant electrometer loomed large in the land. Maxwell himself was deeply immersed in the study of the Cavendish papers, and was enthusiastically repeating those remarkable experiments in which Cavendish had arrived at correct notions of the meaning and magnitude of electrical resistance by making of himself a human galvanometer, estimating current strength by the intensity of the shock he felt in his elbow when the current was discharged through his body. Distinguished visitors were called on, very much against their wills at times, to repeat the experiment, and Sir Joseph's recollections of the period range easily from topic to topic, now sketching Maxwell's work, now moving to a masterly account of Cavendish's meticulously accurate experiments and queer personality and again moved by a recollection of Cavendish's 'gar-do' methods, as the Scots phrase has it, making a neat comparison of Cavendish's and the late Lord Rayleigh's experimental technique, for each experimenter had the gift of seeing what was the vital point in the experiment, so that "though the apparatus as a whole might look untidy and haphazard, the parts that really mattered were all right. It was a 'rum 'un to look at, but a beggar to go'."

Sir Joseph's interests are catholic and his memories are ranging. Figure after figure comes to life, invoked by the power of a kindly memory and a genial pen, and we hear much of the giants of past days, and something of those who are still with us. The portraits of Butler, Thompson and Whewell, Sir Joseph's predecessors in the mastership of Trinity, are skilfully etched, and it is pleasant to recall the personality, sketched from first-hand knowledge, of the Master who reminded his fellows that "we are none of us infallible, not even the youngest". Sir Joseph notes that Thompson had a liking for puns and instances his comment on Courvoisier's execution : "every valley shall be exalted". It would be interesting to know his views concerning the authenticity of what Dean Merivale, who credited the saying to Thompson, regarded as the best classical pun on record. In Merivale's day, a certain fellow named Money retired, took to himself a wife, and developed uxorious habits. The lady duly became as one of those who love their lords and, as the event approached, so waxed Money's uxoriousness. "Quite so," said Thompson, "crescit amor nummi, quantum ipsa pecunia crescit".

But, though Cambridge claims sixty years of Sir Joseph's working life, a portion of it, and that not the least important, lies outside the pale of Cambridge, for Manchester and Owens College claim a share in the shaping of Sir Joseph's genius.

Manchester was a remarkable centre of scientific activity, and the Manchester Literary and Philosophical Society, founded in 1781, had, in the eighteen fifties, three quarters of a century of fruitful work on which to look back. Dalton, Joule, Sturgeon and Henry are names indissolubly associated with Manchester, and the educational influence of the city was further strengthened by the foundation in 1851 of the Owens College, John Owens, a Manchester merchant, having left his estate to be devoted to the establishment of a College free from religious tests. The College, housed in Cobden's old house in Quay Street, was struggling to prosperity when J. J. Thomson entered in 1871. Greenwood was its principal, Barker its professor of mathematics, of whom Sir Joseph remarks, "I have never known a better teacher of mathematics than Barker, and in some respects no one so good". Roscoe taught chemistry, Balfour Stewart physics, Osborne Reynolds engineering ; and when we are told that W. C. Williamson took all natural history for his province, that there was Stanley Jevons for logic and economics, Adolphus Ward for history and English, and Bryce for law, it is obvious that Sir Joseph is making no overstatement when he says that "though Owens College was badly housed, no university in the country had a more brilliant staff of professors".

It is interesting to learn that Sir Joseph's intention was to take up engineering as a profession ; to that end his first three years at Owens College were spent mainly under Osborne Reynolds, "one of the most original and independent of men, who never did anything or expressed himself like anybody else", and it was not until he had received a diploma and a scholarship in engineering that the young student turned his energies towards the acquiring of a mathematical scholarship at Trinity College and embarked on a career which has so profoundly affected the thought of the age.

The hundred or so pages that Sir Joseph devotes to the story of the advances made in physical science in his day end all too soon. It would be difficult to find, within a compass so restricted, a clearer or more enthralling account of the exciting happenings of the days that heralded the discoveries made in our own generation.

Sir Joseph was, perhaps, fortunate in his age ; as he points out, the discovery of Röntgen radiation coincided most happily with the advent of research students at the Cavendish Laboratory, and "to have come upon a method of producing conductivity in a gas so controllable and so convenient as that of the X-rays was like coming into smooth water after long buffeting by heavy seas". The discovery of the electron, the first and most famous of a long series of particles, was not long delayed, and was announced at the historic Friday evening discourse at the Royal Institution on April 29, 1897.

The electron, positive rays, isotopes ; radioactivity, argon, relativity, electron diffraction—the story of these discoveries, discoveries in which the Cavendish Laboratory has played so dominating a part, is unfolded in a pleasantly easy fashion that reminds us that Sir Joseph Thomson is a great teacher, as well as a great pioneer of discovery ; and withal so critical that we are in no danger of forgetting his own wise saying that a scientific theory should be considered as a policy rather than a creed.

In the hurly-burly of modern discovery, we are apt to lose sight of the great volume of work associated with Sir Joseph's name which bears some marks of the influence of his great teacher, Routh. Vortex rings are perhaps not so fashionable as they were fifty years ago, but his applications of Lagrangian methods to problems of physics and chemistry are as fresh now as they were in 1884, and the connoisseur in such matters does not permit the modest little volume containing the exposition of these methods to gather dust upon his shelves.

Much remains that can be no more than noted in passing—poignant memories of the years of War, recollections of visits to America, impressions of adventures in the region of psychical research.

We owe much to Sir Joseph Thomson, and these "Recollections and Reflections" add to our debt. It is impossible to close the book without an increased sense of admiration for a great genius, of affection for a wise and kindly personality.

A. F.

King Coal

Coal:
Its Constituents and Uses. By Prof. William A. Bone and Dr. Godfrey W. Himus. With a supplementary Chapter upon Fuel Economy and Heat Transmission in Industrial Furnaces by Dr. Reginald J. Sarjant. Pp. xvi+631+22 plates. (London, New York and Toronto: Longmans Green and Co., Ltd., 1936.) 25s. net.

THIS important work by very capable authors is one of the most complete and exhaustive treatises on the subject of the constitution and use of coal which has appeared in the English language.

The subject of coal, from whatever aspect one views it, is of outstanding consequence to all students of economics, for, as is well said in the introductory chapter, "the overwhelming supremacy in ship-building and mercantile marine which the United Kingdom had established over all nations by the end of the nineteenth century, was due to cheap coal and iron, favourable geological position, climatic conditions, combined with the policy of free imports".

The authors do not mince matters; it is clear that they are ardent advocates of free trade—and who shall blame them: "the adverse effects of the recent shrinkage of international trade," they say, "have undoubtedly been accentuated since 1931 by the country's departure from free trade", and they advance good reasons for the faith that is in them. They point to the important fact that "the continued production of relatively cheap coal remains the keystone of her [Great Britain's] whole economic structure"—would that our legislators were of like opinion—and that "the World's markets are now in the grip of a pernicious economic nationalism; lofty tariff-walls, import quotas and licenses, and restrictions upon the exports of currencies have combined to hold up the free exchange of goods without which world prosperity cannot be restored". The reviewer is of like opinion, but the difficulty is to determine what action our country ought to take in respect of these barriers to free trade erected by other nations. Every thinking person ought to agree that "neither dear coal nor monopolistic methods will solve the industry's difficulties", though, alas, the trend of present-day legislation is in the direction of such methods.

But this survey of the economic position is merely of an introductory character. The work ranges over a far wider field, dealing, well and truly, with such matters as that of the origin and formation of coals of all kinds; of the coalfields of Great Britain, of weathering and spontaneous heating; of the smoke nuisance and its abatement; of the production of oil from coal; of combustion and heat transmission; of coke, gasification, fuel economy in the manufacture of iron and steel; of power production from coal and of domestic heating.

It is a work which should occupy an important niche in the library of every scientific worker, manufacturer, chemist or engineer—and, I think we may add, of the would-be statesman! If one is not in entire agreement with all the statements and conclusions of the authors, that fact does not in any way detract from one's appreciation of the value of their admirable work. It might, for example, be pointed out that one of the reasons advanced to account for the decline in output of coal (p. 19), namely, fuel economies in power production in iron and steel manufacture, and in carbonization processes, does not accord with Jevons's doctrine to the effect that economy in use of an essential commodity is not conducive to decline in the aggregate consumption of that commodity, but the reverse.

The authors, too, scarcely do justice to the subject of low-temperature distillation of coal, for whilst they state (p. 234) that if the resultant semi-coke "could be made available in adequate quantities at a price comparable with that of a good house-coal, the domestic smoke problem would soon be in a fair way to solution"; yet earlier on in the work (p. 24) they severely criticize the possibility of supplying 30 million tons of semi-coke annually, without advancing any argument in support of their contention which cannot be contraverted. For example, they state that the fuel oil obtained in the distillation is of "inferior quality"; the answer to this is that it is of a quality satisfactory enough to permit of its use by the Royal Navy. Again, that "the transport of vast amounts of solid fuel of lower density than coal would involve formidable difficulties especially in the Metropolis and other large cities". It is difficult to imagine why, seeing that the transport of the semi-coke would present no greater difficulties than in the case of the transport of the gas-coke at present supplied in large quantities. There is no reason why the low-temperature distillation of coal should not be carried out at gas works.

The assertion in regard to the advantage of oil over coal as a marine fuel, namely that "in view of the World's assured abundance of petroleum for the next generation or two there seems little prospect of raw coal recovering what it has lost in that direction", is scarcely warranted. The late Sir Charles Parsons and others, of whom I was one, calculated, some ten years ago, that at the prices then ruling coal, were it used in the most economical way, that is, on chain grates under tubular boilers, with high-pressure steam (600 lb. per square inch and above) to drive turbines, after making due allowance for flexibility in use, saving in labour and gain in space, the advantages rightly claimed for oil, it would be more economical to use coal than oil. I believe that when this fact is fully realized by ship-owners, there will be a return to the use of coal.

The authors are in error (p. 29) in their account of how the chemical survey of the coalfields of Great Britain came to be inaugurated. The Fuel Research Board (which I suggested, in a memorandum drawn up for the guidance of the late Lord Haldane, should be set up for a period of five years to carry out scientific investigatory work for the "Coal Conservation Commission", of which Lord Haldane was chairman and I was a member) consisted of Sir George Beilby, Sir Charles Parsons, Mr. (afterwards Sir) R. Threlfall and myself; following upon a discussion with Prof. R. V. Wheeler, I brought before the Board the subject of a chemical survey of the coalfields and it was agreed to have such a survey carried into effect.

The information contained in Chapter iii of the book relating to the origin, formation and classification of coals is not quite correct in several instances. Thus, the authors are wrong in believing that coal does not exist in any of the geological systems older than the Carboniferous Age. Humic coals exist in the Devonian formation, for example, in the coalfield of Bear Island in the Arctic regions, where seams of 3 ft. 6 in. thickness occur.

In their description of the plants of the Carboniferous period which went to form coal, the authors might have mentioned the fact that the vegetable forms which flourished in the carboniferous period were not entirely of the giant club moss and tree fern, *Lepidodendron* and *Sigilaria* types, for an important constituent in some coals is a true forest tree, *Cordaites*.

On the subject of the origin of anthracite the authors are somewhat hazy (pp. 35, 87). As Strahan pointed out (A. Strahan and W. Pollard, "The Coals of South Wales . . ." *Mem. Geol. Survey*, 1908) the anthracites of South Wales were not derived from humic coals; the mother substances of the two coals differ in the nature of the vegetation of which they consisted or in the biochemical changes to which they were afterwards subjected. He emphasized the low ash content of these anthracites as pointing to the existence of a special type of mother substance. The authors say (p. 87) that "other reasons can be assigned for the lower ash content in question" but do not inform us what the reasons are.

But these are all comparatively inconsiderable errors and omissions. Upon the subject of the fusibility of ash in coal—a very important item in regard to the selection of coals for raising steam, especially where forced draught is employed—as the authors (p. 126) rightly say, "our knowledge is not sufficiently definite to warrant the laying down of any precise rules", though possibly it is related to the fusibility of alumina silicates. They have observed that it increases up to a certain point, "sometimes with its ferruginous character, sometimes, however, with its lime content, and, speaking generally, with the content of some 'most variable' constituent".

The exigencies of space do not permit of further perusing the fascinating subject of the chemical composition of coal, so ably and clearly and exhaustively treated in Chapters ix, x and xi, in which the work of Bedson, Burgess, Wheeler, Porter, Taylor, Discher and Bone, and other workers on the subject is fully discussed.

In regard to the subject of the action of oxygen at low temperatures on coal: the oxidation of coal is, as is now generally accepted, the cause of gob fires, but it cannot be accepted that "anthracites and anthracitic coals are so little affected that they may be considered as practically immune" (p. 194). I used to hold this view, until actual instances of spontaneous heating of anthracite in the mine, not only in the United States of America, but also in one case in a South Wales anthracite mine were brought to my notice.

Concerning the smoke nuisance, it was estimated, some years ago, that the material damage due to this cause in London alone amounts to £4,000,000 annually, and in Manchester, to £1,000,000 in addition to the "immeasurable evil effects of smoke and fog upon public health" (p. 218), a position which would be greatly aggravated by the establishment of super power stations in the proximity of our large towns were it not for the fact that they are compelled to adopt remedial measures. Such a station may burn upwards of one thousand tons per day (p. 231) with the resultant formation of 45 tons of sulphuric acid, 3–7 tons of nitric acid, and about 0·5 ton of hydrochloric acid, the danger from which being the fact that these deleterious substances are emitted from an area of a few hundred square yards instead of from five square miles of a town consuming the same amount of coal in its domestic fireplaces. It is gratifying to learn, however, that "a substantially complete removal is obtained at Fulham and at Battersea power stations by skilfully devised abstergent processes".

The authors deal consummately with the subject of the by-products derivable from coal; of particular interest in this respect is their account of a method of producing *methanol*, a possibility which has been explored since the War, namely, the pressure-catalytic-synthesis of methyl alcohol ('Methanol') from carbonic oxide and hydrogen contained in 'water gas', by exothermic action. A quite recent development of this process—the Fischer-Tropsch process—has resulted in obtaining thereby light oils, waxes and heavier oils, which by another process of treatment can, according to Prof. Fischer, be converted into lubricating oils. This process for the purposes of oil and petrol production may turn out to be a formidable rival to that of the hydrogenation of coal.

But I must bring this review to a close, however enthralling the subject. Enough, it is hoped, has been said to point to the catholicity and profundity of the work and to induce all interested in the subject to read it for themselves. The style is lucid and easy. To each chapter is appended an excellent bibliography. The illustrations are clear and helpful, and the tables, of which there are no less than 136, are not the least valuable part of the work—a work on which the authors are to be congratulated as well as the publishers.

R. A. S. REDMAYNE.

Properties of Carbon Dioxide

Carbon Dioxide
By Prof. Elton L. Quinn and Charles L. Jones. (American Chemical Society, Monograph Series, No. 72.) Pp. 294. (New York: The Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1936.) 37*s*. 6*d*. net.

THIS book is one of the American Chemical Society's valuable series of monographs which fulfil the dual purpose of presenting the available knowledge on the particular subject in a form generally readable by the scientific worker, and of promoting research by furnishing a well-digested survey of the progress already made in the field and by pointing out directions in which investigation needs to be extended.

In the present monograph, a survey has been made of physical, chemical and physiological properties of carbon dioxide, which should prove useful and suggestive, but the reviewer considers that there is a lack of proportion in the monograph as a whole and that too much space has been allocated to the three chapters on the commercial production and application of carbon dioxide in liquid and solid form. It may be mentioned that the two most important applications are the carbonation of beverages, for which the liquid is employed, and the refrigeration of ice cream, which requires the solid form The possibility of commercial application also appears to have influenced somewhat the selection and arrangement of the scientific data, due possibly to the fact that while one of the authors is a professor of chemistry the other was formerly chief engineer to the American Dry Ice Corporation.

In the first two chapters are found the scientific and industrial history of carbon dioxide and an account of its occurrence and functions in Nature. A later chapter of ten pages deals with carbon dioxide in relation to vital processes. Since carbon dioxide is not an active compound, it is perhaps not surprising that twenty-three pages have been found adequate to deal with its chemical properties. The authors themselves point out that the purpose of this chapter is to consider many of the acidic reactions in aqueous solution and to deal also with some reactions taking place in the dry gas. Physical properties are described in great detail in a chapter of seventy-nine pages, but here the authors confess that selection of the best and most reliable physical data is most difficult, and in many cases practically all the recorded data have been included and it has been left to the reader to select those he considers the most useful The remaining three chapters, dealing with manufacture and commercial applications, comprise nearly half the book, although the authors state in their preface that they have made no special effort to paint a picture of the carbon dioxide industry as it exists to-day.

From the preface also it appears that difficulty was experienced in presenting "a well co-ordinated discussion" of "such widely divergent ideas as the natural occurrence of carbon dioxide in Yellowstone National Park, the treatment of skin diseases with solid carbon dioxide and the blasting down of coal with the liquid form". It is suggested that the difficulty has arisen by failure to realize that carbon dioxide itself is the only co-ordinating factor, and whatever ramification the subject may possess it should be possible to adhere to the two purposes which this series of monographs seeks to fulfil.

R. T.

Vitamine und Mangelkrankheiten:

ein Kapitel aus der menschlichen Ernährungslehre. Von Dr. Hermann Rudy. (Verständliche Wissenschaft, Band 27.) Pp. ix+160. (Berlin: Julius Springer, 1936.) 4.80 gold marks.

THIS little book, which is of a size and price that would cause it to be sold for about 2*s*. 6*d*. in Great Britain, avoids many of the characteristics of current German scientific publications. Being of a semi-popular nature, it quite rightly refrains from giving detailed references and also, for the most part, investigators' names.

Few errors have been detected in the text, but the formula given for calciferol is now (and had been for months before this book was published) known to be inconsistent with experimental facts, which demand the presence of a methylene group and three conjugated double bonds. On the other hand, the recent work of Dam and his associates, leading to the recognition of an anti-hæmorrhagic factor, vitamin K, is given notice.

Dr. Rudy's observations (pp. 143 *et seq.*) on "Die Vitamine als Heilmittel" are particularly interesting and significant. Without at any point departing too ostensibly from current orthodox pharmacology, he gets extremely near to suggesting that the vitamins may be regarded, and used, as individual specific therapeutic agents, on the basis of their established physiological action rather than of their 'normal' role in 'natural' nutrition. So far, this view has only been tentatively and timidly adumbrated in speculative or controversial articles, but seldom, if ever, put forward in print for serious consideration by those who direct official medical and biochemical opinion. That it should now be implied or expressed in a book, and in a German book at that, seems to the reviewer a sign of the times. A. L. B.

Memoir on Fossils of the Late Pre-Cambrian (Newer Proterozoic) from the Adelaide Series, South Australia

By Sir T. W. Edgeworth David and Dr. R. J. Tillyard. Pp. xi+122+13 plates. (Sydney: Angus and Robertson, Ltd.; London: Australian Book Co., 1936.) 7*s*. 6*d*.

THIS volume appears to have been issued as a memorial to the late Sir Edgeworth David. It gives a fuller and more detailed account of the work published in 1928, of which a notice appeared in NATURE (123, 659). The supposed fossils were found in the Adelaide Series near Adelaide, and are regarded as indicating the existence of Algæ, Radiolaria, annelids and arthropods in pre-Cambrian times. The specimens which have been seen in England are far from convincing, but it is claimed that as the result of the mass effect of a very large collection "no Australian scientist, whether palæontologist, zoologist, or geologist, who has taken the trouble to study the specimens, has any doubt whatever as to their being genuinely organic".

The chief addition in this volume is an account of the supposed arthropods by Dr. R. J. Tillyard. He maintains their arthropod nature on the grounds that the specimens, although fragmentary, do show evidence of bilateral symmetry, segmentation, segmented appendages and sculpture. After comparing them with various groups of arthropods, he concludes that they show some relationship to the Eurypterida, but that they are more primitive than any known arthropods, and must be placed in an independent class, since the prosoma is formed of distinct segments, each with a pair of appendages. The abdomen is regarded as formed of seven segments, but without segmented appendages. The restorations give a clear idea of Dr. Tillyard's interpretation, but we cannot test their validity from the evidence of the specimens figured. An excellent portrait of the late Sir Edgeworth David forms the frontispiece to the volume.

Ziema:

Fizyka globu, mórz i atmosfery. Napisał Dr. Edward Stenz. (Z Dziedziny Nauki i Techniki, Tom 11.) Pp. xiv+303+26 plates. (Warszawa: "Mathesis Polskiej", 1936.)

THIS comprehensive Polish work on the physics (and incidentally much geology) of the globe, the sea and the atmosphere is a noteworthy publication and does credit to its author and his nation. It opens with a brief history of astronomy with reference to the earth and its relation to the sun, moon and planets. This is followed by a sketch of the geological epochs and such physical and chemical considerations as the magnetism and composition of the interior of the earth.

The section devoted to the sea is concerned with its magnitude and saline contents, and with tides and inundations. The role of the atmospheric envelope and the stratosphere and phenomena associated with them are considered, and in his final section the author discusses various cosmic phenomena, the age and probable fate of the world. Discoveries by Polish savants are referred to in detail and emphasis is given to matters of direct interest to Polish students. Thus, illustrations and examples are drawn wherever possible from local sources.

Food and the Principles of Dietetics

By Dr. Robert Hutchison and Prof. V. H. Mottram. Eighth edition. Pp. xxvii+634+3 plates. (London: Edward Arnold and Co., 1936.) 21*s*. net.

WHEN this work was first published, thirty-six years ago, little attention had been given in Great Britain to scientific problems relating to food and human dietetics. The authors were among the pioneers in this field, and their work greatly assisted in creating new interest in the subject. In the eighth edition, now available, the history of dietetics is outlined in a new chapter in which it is pointed out that "If the nineteenth century was the quantitative epoch of dietetics the present century has so far been a qualitative epoch". The great advance of knowledge of food and nutrition has necessitated a number of changes and additions, and these will serve to maintain the position of the volume as a readable account of human foods and principles of feeding, as well as an authoritative work of reference.

Soil Science in the Twentieth Century*

By Prof. J. Hendrick

MOST of our scientific knowledge of the soil has been built up during the past century. It was only with the development of modern science, and especially of chemistry and geology, that such knowledge could advance, and it was about a century ago that our early knowledge of the chemical composition and mineral constitution of the soil was built up. This knowledge has been advancing ever since but with particular rapidity during the present century.

Soil science in Great Britain was in a comparatively stagnant state at the beginning of this century. Britain had done much in the development of the fertilizer industry, though even in this, while other countries were advancing rapidly, we had been falling somewhat into the background during the last quarter of the nineteenth century.

A comparison of the text-books on agriculture and agricultural chemistry of the beginning of the century with those of the present day will illustrate the great change in outlook on soil science. There were no British text-books on soil science in 1900. Any text-books on this subject in English were American. Our knowledge of what was being done by soil investigators abroad was not extensive; of what was being done in Russia we knew nothing.

Britain is a comparatively small country falling within ten degrees of latitude, with a climate which is in all parts temperate and humid and with a rainfall which is well distributed throughout all seasons of the year and which varies from moderate to high. The soils of Britain had not been studied even over the whole limited range of the country, but almost entirely in a small region in the south-east and mainly at Rothamsted and Woburn. These were looked upon as typical soils, and all others were supposed to be more or less similar. If that was not definitely stated, it was tacitly assumed. It may be said that until the present century, and even until the second decade of the present century, our view of soils was narrow and insular. All others were expected to conform to "This blessed plot, this earth, this realm, this England", and it was a most blessed plot of the south-east of England which was the standard.

We did ourselves no good service from an imperial point of view by taking such a narrow and insular view of soils. While Britain is a small country of limited latitude and climate, the British Empire exists in every latitude and every kind of climate. In agricultural science and not least in soil science, great sections of the British Empire, not merely Canada, but Australia and South Africa as well, came to look to the United States rather than to Britain for information and guidance.

There are two great countries which, unlike Britain, extend through wide ranges of latitude and climate. These are Russia and the United States. Russian territory extends from arctic tundra to the subtropical, and embraces every kind of climate from warm humid and cold humid to arid and desert. The same is true of the United States, especially if we include Canada, which, in this respect, is in very close association with the United States, whose workers keep in view the soils of the whole North American continent.

The scientific work of the United States is published in English and is therefore always easily accessible to us. Russia, on the other hand, is cut off from us by the barrier of a language which few can read, and the remarkable soil work which was going on in Russia and has now produced such a great change and widening of the views of soil investigators throughout the world, was unknown in Great Britain until after the Great War, when it began to filter through to us from America, Germany and other countries.

What are these fresh views which we all sat at the feet of the Russians to learn? They treat the soil as an independent natural object worthy of study for its own sake and not merely as a useful medium in which to grow crops, or as a subsidiary branch of geology or chemistry or any other science. The branch of science which deals with soils they treat as an independent branch, which they call pedology. Many people in Great Britain and in America have now adopted this term and prefer to be pedologists—a word not in the dictionary—rather than soil scientists. My own preference is for a term which is readily understood by ordinary people.

Next, the Russians insist that the soil is the natural product of a number of soil-forming factors of which the most important is climate, and that its nature is not determined by its geological origin. Their great primary classification of soils is into a number of climatic zones. The most notable feature in the whole Russian philosophy of soils is the insistence on the importance of climate as a soil-forming factor. Climate plays the central part in their system of soil classification. This recognition of climate is not entirely a new idea. Hilgard in America, and others, had already shown that climate has a great effect on the nature and composition of soils.

---

* From the presidential address to Section M (Agriculture) of the British Association, delivered at Blackpool on September 14.

In the old Russian Empire, and the modern union of Soviets, there are soils which have been produced in a great variety of climates in Russian Europe and Asia. The Russian soil workers set themselves to collect these and to examine them critically, and came to the conclusion that soils produced from a geological formation in a cool climate were very different from those produced from the same geological formation in a hot climate, and that those produced in a moist climate were very different from those produced from the same parent materials in an arid climate. In fact they showed that soils cannot be classified and characterized on a geological basis. Possibly some of them, and still more some of their enthusiastic converts in other lands, go too far in excluding geological origin altogether as a factor in soil formation.

The next great feature of the Russian system is the classification of soils according to what is found in the soil profile. The profile, as is now well known to all of us, though that was not so twenty years ago, is a section of the soil from the surface down to the parent material. If such a section is examined, it is almost invariably found to consist of a number of different layers, called horizons, which are generally easily distinguishable from one another. When a great many such profiles are examined from different parts of the world it is found that they fall into a number of definite types characteristic of the different types of soil. The profile is an expression of the results of the different soil-forming factors, and therefore characterizes the different types of soils as produced by the action of these factors. This is expressed by saying that the profile is the resultant of the pedogenic processes. The modern soil surveyor studies morphology of soil profiles and classifies his soils accordingly.

This is in outline very simple; in practice it is often very difficult, and is apt to give rise to differences of opinion, especially when those accustomed to the profiles of one part of the world are introduced to a new region with conditions different from those to which they are accustomed. It will be seen, too, that this scheme of a profile made up of horizons is a development of the old division of the soil into soil and subsoil. But there is an important difference; the terms soil and subsoil were applied to cultivated soils mainly, and the soil was, generally speaking, the layer which had been mixed and influenced by the implements and processes of cultivation, while the subsoil was the layer which was not touched by instruments of cultivation. Such a division is of no use to the modern student of soil morphology and genetics. The processes of cultivation have turned over and mixed the surface layers and have also modified those below the region reached by the plough The modern soil investigator, therefore, insists that the profile must be studied in undisturbed soil which has existed in its natural condition for a long period of time. To him the profile is the soil unit which must be studied as a whole, unmodified by artificial operations of man. This of course introduces difficulties in old settled countries of dense population, like our own, where most of the soils which are worth cultivation have been broken up and cultivated at one time or another. In the extensive, lightly populated areas of Russia or North America there are plenty of natural soils; but in applying modern methods of soil study to the soils of much of western and southern Europe and other regions of ancient civilization, modifications have to be introduced to allow for the influence of cultivation which, in many cases, extends over long periods of time.

The whole of the processes of soil formation are very complex and require much more study before we can hope to reach, I will not say a final, but a sound system of soil classification. The soil itself is, from every point of view, a very complex and variable material; and our present methods for its study and classification, though a great advance on what went before, are of very recent origin, and no doubt further great progress will be made as a result of the intensive studies to which soils are now being subjected in many lands.

In the above sketch I have merely referred to one or two features of the Russian soil philosophy which appear to me to be outstanding. Much of the Russian soil science is at present remote from agricultural practice. It is curious that in spite of their theories of Government and of five-year plans for the rapid practical improvement of the condition of the people, the Russians are the champions of pure soil science, of the view that our study of soils should proceed without reference to any use that may be made of such knowledge for the service of agricultural practice, or for the production of wealth from the soil.

The fundamental importance of soil moisture has been known for ages. Without water, crops cannot grow, and with excess of moisture we get marsh or swamp and our ordinary crops are drowned out. A proper supply of moisture is more important to crops than all the fertilizers put together. In the modern theory of soil formation and classification the important part played by water is recognized. The two important factors in climate, those which do most to determine what the soil is to be, are the supply of water and the temperature. In considering water supply it is not sufficient to consider the rainfall—the humidity, the distribution of the rainfall and the topography all enter into the picture. A rainfall which is sufficient to wash through the soil and leach away soluble constituents in a cool humid climate may all be re-evaporated and leave nothing to wash through the soil in a warm climate with a dry atmosphere. Again, if all the rain falls at one season of the year a part of it may seep through the soil and escape as drainage water, while if the same rainfall is distributed throughout the year so much may be re-evaporated that there will be none to escape as drainage.

Considering the importance in soil formation of water which passes through the soil, and of the amount and nature of materials in solution and suspension which are washed away by such water, or removed by it to lower layers of the soil, and the importance to soil fertility of the relations of the soil to water, and of the economic importance of drainage in connexion with the loss of nitrogen, lime and other manurial constituents from the soil, it has always been a matter of surprise to me that more use is not made in soil studies of drain gauges or lysimeters, or instruments of a similar kind.

The first drain gauges, so far as I am aware, were made by Lawes and Gilbert at Rothamsted more than sixty years ago. They were designed to study evaporation and percolation in relation to depth of drainage, and were therefore of different depths, 20, 40 and 60 inches respectively. They were also used to study the amount of nitrogen washed away from uncropped and unmanured soil. The blocks of soil enclosed in these drain gauges were never broken up, they were built with as little disturbance as possible into the water-tight structures which enable the drainage to be measured. They consist therefore of real soils which have been formed by a long course of natural soil-forming processes. Similarly the drain gauges which I have had built at Craibstone, near Aberdeen, have been formed by enclosing, without disturbance, in water-tight boxes of Caithness slate, blocks of natural soil which have never been broken up. My drain gauges are intended to study the changes which take place in cultivated soil, and the losses which take place in the drainage water during ordinary processes of cropping and manuring.

Such drain gauges are not easy to construct. I suppose that is why this method has been so little used in the study of soils. It is much easier, and cheaper, to build a water-tight box and fill subsoil and soil into it, than it is to enclose a block of natural soil, weighing several tons, in a water-tight structure. If the easier method is adopted, as has been done to a large extent in America and elsewhere, its limitations must be recognized. The soil, once it is broken up and filled into a lysimeter, is no longer a natural soil, and it is difficult to say how long it will take under the influence of the soil-forming processes of the locality to become once more a real soil such as is provided in Nature.

The development of our knowledge of soil colloids and base exchange during the present century is second in importance only to the advance which has been made in the science of soil formation, structure and distribution. The beginnings of our knowledge of this subject can be traced back to the middle of last century when Way showed that the ammonium of ammonium sulphate, or the potassium of potassium sulphate, was retained by the soil while an equivalent amount of calcium went into solution and could be washed away as sulphate. He also showed that this power resided in the finest mineral part of the soil, the clay, and he regarded the action as an ordinary case of double decomposition between clay and the soluble, neutral salt in solution.

Though there was much discussion about these phenomena, which were regarded as of the greatest practical importance because they showed that valuable manurial bases when applied in a soluble form could be absorbed and retained in the soil, and though soil investigators of last century were divided into two camps, one regarding this fixation of bases as a chemical precipitation by double decomposition and the other looking upon it as a physical process of absorption, little further advance was made until the present century. By that time, considerable advance had been made in our knowledge of colloid chemistry, and we also knew that there were two types of colloid complexes found in soils, one mineral and the other organic.

We now know that this process of base exchange is a colloid phenomenon, and follows the laws of colloid chemistry. It is not confined, as Way supposed, to the fine mineral matter of the soil, but is a property of the organic colloids also. The old controversy as to whether this is a chemical or a physical phenomenon is thus cleared up and both sides are shown to be right or both wrong, according to taste, for both sides knew nothing of that border-line field of colloid phenomena where physics and chemistry blend, and, in the best modern manner, tend to become indistinguishable.

Our knowledge of the chemistry of humus, in spite of the great amount of work which has been done upon it in recent years by workers in many countries, is still in a state of doubt and darkness, but in the last few years we have learned a great deal about the chemical structure of clay. The application of X-ray methods of analysis has shown that much clay material exhibits a definite lattice structure, and that there are several different minerals, showing at least two different types of lattice structure, to be found in clays. Some light has also been thrown by this work on the nature of the base exchange capacity of clay and on the great differences in base exchange capacity which are found in different types of clay substances.

One cannot give a very hopeful account of the progress of our knowledge of humus. We have not yet found any clear method of unravelling its structure and of showing what is the nature of the colloid molecules which build up the main part of this very important soil constituent.

In many other directions, fundamental soil science has made in this century, and is making, marked advances. Fertilizers, for example, we may class along with the soil, for they are substances used to increase the productivity or make up the deficiencies of the soil. From small beginnings a century ago, the fertilizer industry has grown to be one of the world's greatest chemical industries. In the early days of the industry Great Britain played a notable part, but in the latter part of last century and the early part of this one, when the whole of our soil science was in a somewhat backward position, our fertilizer industry also fell into the background. We have recently seen a great revival consequent upon this industry again becoming scientific instead of depending merely upon commercial and business ability. For this change and improvement we may, I think, give much of the credit to Imperial Chemical Industries, Ltd., who are now our greatest fertilizer manufacturers, and who make the manufacture of manures an important section of their business. The older type of fertilizer manufacturers may have employed a few works analysts, but they did not pay for the best scientific brains to help them to introduce new processes and to improve old ones. That has been changed by I.C.I., and we have a new spirit in the fertilizer industry and we are regaining something of the great position we once held in that important branch of chemical manufacture. It is to be hoped that this will continue. If we are not to fall back into the old state of lethargy we must continue with long-range research, as the Germans and Americans are doing, carried out by educated and competent persons. That is the only way if we are to continue to advance and keep in the front.

Physics is not the only branch of science in which revolutionary changes have been made in the twentieth century. Even in soil science we have seen a structure built up which the agricultural chemists of a generation ago would find strange. In the British Isles at the beginning of the century there was almost no soil science; now we are taking our due part in building up and nurturing this branch of knowledge. We have now not only the great station at Rothamsted but also the Macaulay Institute at Aberdeen, which is engaged in the study of soils of different types from those of the south-east of England and is approaching soil study from a somewhat different angle. There are also in our universities and agricultural colleges quite a number of soil investigators of distinction who are dealing with the soils of many other parts of the country. At the same time, it is probably true to say that in Britain the fundamental attitude towards soil study remains the same. It is difficult for us to achieve the complete detachment of the Russians and study soils entirely apart from any practical agricultural applications which our studies may have.

But to what are we heading ? Of what use is it all ? Are we only increasing sorrow by increasing knowledge ? Our increased knowledge should give us increased power to use the soil, and that surely means increased production. We are told there is already over-production and that what is required is restriction of production. We read in our papers of crops being destroyed because they cannot be used, or because it does not pay to harvest them. In the United States, and elsewhere, the growth of fundamental food crops, like wheat, has been restricted. In Great Britain arable land is decreasing while at the same time the import of foodstuffs is being restricted.

Has everybody in this country, and in every other country, too much, or even enough, food ? Do we not, at the same time as we are crying out about over-production, hear an equal outcry about malnutrition and under-feeding even in this comparatively prosperous country ? The two things do not fit together. They cry out against one another. They cannot both be right. But we all know that there are many people, forming quite a large section of the population, who have not over-abundance, who have not even enough. This, which is true of Great Britain, is, unless we are strangely misinformed, true in a much higher degree of the world at large. This is not a problem of soil science, but a problem for the statesman, the social reformer and the economist. The soil scientist can safely go on and increase our knowledge of soils, and hope that, in the long run, it will increase production and lessen labour. Increased wealth, especially in the essential things produced from the soil, is a blessing, not a curse, and if it can be obtained more easily, and more certainly, through the power and control provided by increased knowledge, that is all to the good.

The solution of our difficulties must be looked for by the increase of impartial scientific knowledge in other directions. It is our social organization, our statesmanship, our economic system which are at fault when the abundance which is produced cannot be brought to the many who are in need of it. Social and political sciences and even economic science are no doubt applying themselves to this problem, and let us hope they will be able to remove it from an atmosphere of social prejudice and party bias to the calm, truth-seeking atmosphere of pure scientific investigation. Agricultural science can go forward fearlessly to increase knowledge in the good hope and belief that increased knowledge will be in itself a blessing.

Cancer Research in Great Britain

THE thirteenth annual report of the British Empire Cancer Campaign was presented at a meeting held at the House of Lords on November 23. The report gives an effective summary compiled by institutions and individuals of the greater part of British research on malignant disease. The field of cancer research may be divided into three parts : the origin of the disease ; the nature of malignant growths ; and the effect of treatment in alleviating or curing the disease. Investigations in man, in animals and in cells growing outside the body in tissue culture have been made in all three directions during the last year.

Attempts to understand the nature of the processes which cause cancer in man have been made by studying cancer mortality according to the organ in which it occurs in different districts and different occupations. Observations of this kind have in the past indicated that coal tar and certain lubricating oils might be carcinogenic and so lead eventually to the isolation of the pure carcinogenic compound, benzpyrene. Previous investigation into the mortality from cancer in different countries has shown surprising differences, such as the high incidence of liver cancer in the East and its comparative rarity in Europe. In Switzerland, cancer of the œsophagus is more frequent than in the rest of Europe. Dr. Stocks, of the General Register Office, has examined the geographical distribution of 522,251 deaths occurring between 1921 and 1930 from cancer in the counties of England and Wales. He has calculated the "actual mortality per cent of that expected from the distribution of population by age and class of district". The results are depicted in a series of maps. Some of the more outstanding differences are shown in the accompanying table.

Death from cancer of all sites is more common than would be expected in North Wales and unexpectedly rare in Radnor and East Suffolk. In Wales, gastric cancer is frequent, and Carnarvonshire accounts for more than twice the expected number of deaths, but lung cancer is rather infrequent. The results show resemblances between the distribution of œsophageal cancer and rectal cancer, while the distribution of gastric cancer is quite different. The distribution of the ratios for breast cancer is much more uniform than for any other type of cancer shown. It is as yet impossible to determine whether these differences are due to genetical factors, to geological or meteorological conditions, to the different diets and habits of people, or to the difference in accuracy of diagnosis.

DEVIATION OF ACTUAL MORTALITY FROM THAT EXPECTED FROM THE DISTRIBUTION OF POPULATION BY AGE AND CLASS OF DISTRICT.

	High Incidence	Low Incidence
All sites (males)	Flint, London, Huntingdon.	East Suffolk, Radnor.
All sites (females)	Anglesey, Merioneth	Radnor.
Stomach (males)	Ely, Anglesey, Carnarvon, Denbigh, Merioneth, Montgomery, Pembroke.	East Suffolk.
Stomach (females)	Anglesey, Carnarvon, Denbigh, Merioneth, Pembroke.	West Sussex.
Œsophagus (males)	Berkshire.	Durham, Lincoln (Holland and Lindsey), Northumberland, Nottingham, Merioneth, Monmouth
Skin (males)	Lincoln (Holland), Anglesey, Cardigan	Gloucester, Carnarvon, Radnor
Lung (males)	Hertford, London, Middlesex, Essex, Nottingham.	Berkshire, Cumberland, Devon, Dorset, Durham, Gloucester, Lincoln (Holland), Northampton, Suffolk, all Wales except Flint.

Prof. E. L. and Mrs. Kennaway have computed the incidence of death from cancer of the lung and larynx in a large number of occupations, for the years 1921–32. During the period 1919–34 there was an eight-fold increase in the mortality from lung cancer. The cause of this increase has not been identified, but it does not appear to be due to urbanization as the relative increase among agricultural workers is only slightly less than among the total population. Workers exposed to coal gas and tar and those engaged in tobacco and metal grinding trades show high susceptibility, while coal miners, cotton spinners and agricultural workers have a low susceptibility to lung cancer. This latter finding is reflected in one of Dr. Stocks's maps. Mortality from cancer of the lung is less than would be expected in agricultural areas and in the mining areas of South Wales, Cumberland and Durham.

Results obtained in studying the effect of X-rays and radium on malignant growths are reported from many centres in Great Britain, Australia and Canada. In treatment there has been a tendency to utilize deep X-ray therapy for lesions in which radium has previously been usually employed. An interesting development of X-ray technique is the use of the low-voltage (60,000 volt) tube advocated by Prof. H. Chaoul of Berlin With this instrument the actual source of the X-rays can be placed within a few millimetres of the tissues. It is as yet too early to compare this with the older methods, but it should be advantageous in certain cases. The comparison of results obtained by different methods of therapy will be simplified by the adoption of a standard method of recording cancer cases in different hospitals. The value of such standard records is enhanced now that it is realized that accurate dosage is important for successful treatment. It is essential to protect the operators from stray radiation, and workers in some centres carry small charged condensers, the amount of discharge occurring in the condenser gives a measure of the radiation and acts as a warning or tell-tale to the therapist.

X-rays and radium are both able to produce tumours and also to destroy them. Dr. A. Haddow has found that several chemical agents which produce cancer when applied to animals also inhibit the growth of tumours. The inhibition appears to some extent specific for carcinogenic agents, although feebly-carcinogenic and non-carcinogenic compounds are sometimes inhibitory. Many non-carcinogenic compounds have no growth-inhibiting effect. Not only tumour growth but also body growth is decreased by treatment with carcinogenic hydrocarbons, and it is suggested that the carcinogenic action is the result of a restraining action rather than stimulating action on cell growth. The movement of the fluorescent carcinogenic hydrocarbons in the body has been observed in a darkened room under ultra-violet illumination by Dr. P. R. Peacock. He finds that colloidal particles of hydrocarbons are rapidly removed from the blood stream by the liver and then excreted into the intestine, dissolved in bile. It is possible that the compounds are reabsorbed from the intestine into the blood stream.

The first known pure carcinogenic compound was 1 : 2 : 5 : 6-dibenzanthracene, and it is interesting to see how its molecular structure can be modified without destroying the biological activity, as shown by further work at the Royal Cancer Hospital. 1 : 2 : 5 : 6-dibenzfluorene, in which the 6-membered central ring is replaced by a 5-membered ring, is carcinogenic. 1 : 2 : 5 : 6-dibenzacridine and 3 : 4 : 5 : 6-dibenzacridine, in which one of the central carbon atoms of the original compound is replaced by nitrogen, are carcinogenic. While 1 : 2 : 5 : 6-dibenzanthracene is much more active than the 1 : 2 : 7 : 8- (or 3 : 4 : 5 : 6-) compound, 3 : 4 : 5 : 6-dibenzacridine is much more active than 1 : 2 : 5 : 6-dibenzacridine. If two carbon atoms are replaced by nitrogen as in 1 : 2 : 5 : 6-dibenzphenazine the activity disappears. Other new carcinogenic compounds are 1 : 2 : 5 : 6-dibenzcarbazole and 3 : 4 : 5 : 6-dibenzcarbazole, which may be considered as dibenzfluorene compounds with one nitrogen in place of one central carbon atom. These compounds resemble the acridine derivatives in that greater activity is associated with the 3 : 4 : 5 : 6-configuration. Painting of mice with 3 : 4 : 5 : 6-dibenzcarbazole produces epitheliomata on the skin and proliferation of the bile ducts, and nodules resembling hepatoma in the liver.

Some derivatives of 1 : 2 : 5 : 6-dibenzanthracene have considerable œstrogenic activity. Profs. Cook and Dodds and Dr. Lawson have shown that 9 : 10-dihydroxy-9 : 10-di-*n*-propyl-9 : 10-dihydro-1 : 2 : 5 : 6-dibenzanthracene can fully reproduce almost all the biological effects that are known to be produced by the natural hormone œstrone. New compounds have now been tested which have œstrogenic activity but do not contain the phenanthrene nucleus. The most active of these new substances appears to be 1 : 2-dihydroxy-1 : 2-di-α-naphthylacenaphthene and the simplest compound known to have œstrogenic activity is 4 : 4′-dihydroxy diphenyl.

Further work on the relation of ovarian hormones to cancer is reported. Mr. Burrows obtained mammary tumours in castrated male mice which were painted with a benzene solution of œstrone. Dr Bonser has compared the reaction of male mice of two pure strains to painting with œstrone. In one agouti strain, in which spontaneous mammary cancer never occurs, there was widespread generalized growth with production of acini but no production of mammary cancer. In an albino strain, the females of which often develop mammary cancer, the males treated with œstrone showed a more localized acinar development, and this was associated with the development of mammary carcinoma. The results show how reaction to œstrone is dependent on the ancestry of the animals used, and also how the two factors, heredity and environment, are concerned in the origin of malignant disease. There is little doubt that when we can fully account for the distribution of human cancer in terms of these factors, we shall be near to the solution of the problem of the prevention of the disease.

The Observational Approach to Cosmology

SINCE its first announcement by Dr E. P. Hubble in 1929, the existence of a linear relation between 'velocity' and distance among the extra-galactic nebulæ has excited a great deal of theoretical interest, the more so since it appeared to be a direct confirmation of the instability of the Einstein universe predicted by Lemaître. It was therefore not unfitting that the discoverer of the relation, himself a Rhodes scholar, should have been invited to deliver the Rhodes Memorial Lectures in Oxford on October 29 and November 12 and 26, or that he should have used this opportunity to present the observer's interpretation of the wealth of material since accumulated on this problem by himself. The lectures, which dealt in turn with the observable region, the role of the red-shifts, and possible models of the universe, have revealed that a static universe with a hitherto unsuspected dependence of light frequency on distance is probably more acceptable than one or other of the homogeneous expanding models of general relativity.

This startling conclusion depends in a very large measure on the 'luminosity' methods of distance determination necessarily used for the extra-galactic nebulæ. The intrinsic luminosity of the average extra galactic nebula having been determined by means of the Cepheid variables found in nebulæ of the 'local group', the distance of any nebula can be found from its apparent luminosity and the inverse square law. The apparent luminosity is, however, affected by the observed redward displacement of the spectrum. Assuming that the energy distribution in the spectrum of an extra-galactic nebula is similar to that of the sun, as is very nearly the case, and correcting for atmospheric absorption, reflectivity of the telescope and plate sensitivity, one can find empirically the correction, Δm_1, to be applied to the apparent photographic magnitude for any desired red-shift; with sufficient accuracy this correction is given by $\Delta m_1 = 3\Delta\lambda/\lambda$. If, however, the nebulæ are actually receding from us, an energy correction alone will not suffice, but in addition a correction must be made for the fact that we receive fewer quanta per second from a receding nebula than from a stationary one. This correction amounts to $\Delta m_2 = \Delta\lambda/\lambda$. Clearly the apparent luminosity to be used in finding the distance of the nebula from its intrinsic luminosity and the inverse square law will depend upon whether the nebula is receding or not, and if there were only some independent means of distance determination the presence or absence of recession could be immediately inferred. Even in the absence of an independent method of distance determination, it is still possible to make some progress in distinguishing between recession and non-recession by counts of nebulæ.

If the total number of nebulæ, or the number of nebulæ per square degree, are counted to different limiting apparent magnitudes, and these limiting magnitudes after the appropriate corrections for recession or non-recession converted to distances, the nebular counts will yield immediately the spatial distribution of nebulæ as a function of distance. In his recent lectures, Hubble used five nebular counts to limiting apparent magnitudes 18·5, 19·0, 19·4, 20·0 and 21·0, the second of these counts having been made by Mayall with the 36-in. Crossley, the remainder by Hubble with the 60-in. and the 100-in.; the last count, it is interesting to note, is within half a magnitude of the limit set for the 100-in. by scattered sky light. Correcting these limiting magnitudes for energy effect alone (no recession), the five counts are perfectly represented by the relation

$$\log N(m) = 0{\cdot}6\,(m - \Delta m_1) + \text{constant}.$$

This linear relation is precisely that which would hold if the spatial distribution of the nebulæ were uniform out to the limit of the counts, that is, to a distance of some five hundred million light years. We can interpret this result to mean that we are seeing only a portion of a much larger universe, a portion within which the spatial distribution of nebulæ is uniform, and a universe in which the frequency of a light quantum varies linearly with the distance. Without in any way straining the observations, but at the expense of a newly postulated property of radiation, we can describe the nebular counts in terms of a simple static universe.

If, on the other hand, the limiting magnitudes of the nebular counts are corrected for recession as well as for energy, the resulting apparent spatial distribution is one centrally symmetrical about the galactic system with necessarily increasing spatial density outwards. Since our galactic system appears to be closely similar in intrinsic luminosity and mass to the nebulæ whose density distribution we are discussing, there is no reason why the galactic system should occupy so dominant a position in the universe, and we must regard this spatial distribution, found when we assume the nebulæ to be receding, as only apparent. On

Milne's original kinematic model of the universe, this outward increase in density is just what would be expected from the fact that we do not have, as it were, an instantaneous view of the universe, but are seeing the more distant nebulæ as they were some five hundred million years ago. When the observed density distribution is corrected to the instantaneous view, the resulting spatial distribution turns out to be uniform ; since on the kinematic model, however, uniform density distribution can only occur once, Hubble finds it nearly as unsatisfactory to suppose that we are just happening to observe the universe at a special instant in time, as if we were observing from a specially favoured point in space

Still assuming that the observed red displacement is due to a velocity of recession, and that therefore the apparent spatial distribution of nebulæ increases radially outwards, Hubble next examined the apparent distribution of nebulæ predicted by the homogeneous expanding models of general relativity, a special case of which also includes in many of its aspects Milne's kinematic model. Tolman has shown that the nebular counts predicted by these models take the form

$$\log N(m) = 0{\cdot}6\,\{m - \Delta m_1 - \Delta m_2 + F(R)\}$$

where R is the radius of space curvature. At the very outset an almost insuperable difficulty is encountered in that the observed counts do not obey a relation of this form. If, however, it be assumed that the observed counts are subject to almost impossibly large systematic errors, the relation and the observations may be used to calculate a value of R. The resulting value is of the order of five hundred million light years, rather less than the penetrating power of the 100-in. telescope, and since there is a relation between R and the density of matter in space, the density must be 10^{-26} gm. cm.$^{-3}$, which is many times greater than the mean density produced by the nebulæ alone. To account for this density we must postulate that inter-nebular space is filled with matter the mass of which is greatly in excess of the total mass of the nebulæ, and which is distributed in such a form as to produce no absorption of light in space, since any absorption would demand a still smaller radius of curvature and larger mean density.

If no recession is assumed, the observed nebular counts are satisfactorily described by supposing that we are observing a finite portion of a much larger universe of nebulæ, but a universe in which the frequency of light varies uniformly with the distance. If, on the other hand, recession is assumed, the observed nebular counts are not satisfactorily described by any of the homogeneous expanding models of general relativity, but if forced to fit require that the universe be closed, that we have already explored it to its outmost bounds with the 100-in. telescope, and that it is a universe dominantly filled with non-luminous matter distributed in such a way as to absorb or scatter negligibly small amounts of light.

The large and appreciative audiences who followed the three lectures, each a model of exposition and clarity, had little difficulty in agreeing with Dr. Hubble that the consequences of assuming no recession were the less difficult to accept.

H. H. P.

News and Views

Prof. A. N. Talbot

Prof. Arthur N. Talbot, emeritus professor of engineering in the University of Illinois, has been awarded the John Fritz Gold Medal, the highest of American engineering honours. Prof. Talbot, who is seventy-nine years of age, was cited as "moulder of men, eminent consultant on engineering projects, leader of research, and outstanding educator in civil engineering". The award is made annually by a board composed of sixteen past-presidents of the four national societies of civil, mining and metallurgical, mechanical and electrical engineers. Prof. Talbot was born in Cortland, Ill., on October 21, 1857. He has been engaged in engineering work since 1881, his activities embracing railroads, roads, bridges, buildings and municipal public works. Prof. Talbot aided in the development of the testing laboratories and the College of Engineering of the University of Illinois. He has been active in the formation and development of the Illinois Engineering Experiment Station, in connexion with which he has made numerous investigations in the properties of steel, brick, concrete and reinforced concrete, and in water purification, sewage treatment and hydraulics. Among previous recipients of the John Fritz Gold Medal have been Lord Kelvin, Thomas Edison, Guglielmo Marconi, Elihu Thomson and Sir Robert Hadfield.

Sir Robert Mond

Sir Robert Mond has been elected an associate foreign member of the Académie des Inscriptions et Belles Lettres in Paris, in succession to the late King Fuad of Egypt. Sir Robert Mond's wide interests are illustrated by the fact that he is honorary secretary of the Davy Faraday Research Laboratory at the

Royal Institution, chairman of the Norman Lockyer Observatory Corporation, and also president of the Egypt Exploration Society; he is a Messel medallist of the Society of Chemical Industry, a past president of the French Society of Chemical Industry, and he has carried out noteworthy archæological excavations at Thebes, in Palestine, and in Brittany. The museum at St. Germain has been much enriched as a result of his excavations in Brittany. The Académie des Inscriptions, by its election of Sir Robert as a foreign associate member, has attracted to its service one whose knowledge in many fields can scarcely fail to promote its activities and influence.

Prof. A. F. Burstall

Dr. Aubrey F. Burstall has been elected professor of engineering and dean of the faculty of engineering in the University of Melbourne, Australia. Dr. Burstall is a son of the late Prof. F. W. Burstall, who was professor of mechanical engineering in the University of Birmingham in 1896–1931. Dr. Burstall, who is thirty-four years of age, received his education at King Edward's School (New Street), Birmingham, at the University of Birmingham and at St. John's College, Cambridge. The results of his work on the combustion of various gaseous fuels in the high-speed internal combustion engine were published in a series of papers before the Institution of Automobile Engineers. Dr. Burstall joined in 1925 the staff of Synthetic Ammonia and Nitrates Ltd. at Billingham, which in 1928 became a constituent company of Imperial Chemical Industries Ltd. He held various positions of increasing responsibility on the engineering staff and in 1930 was appointed deputy chief engineer of the Billingham Factory. In 1933 he resigned his position to become technical adviser to the Aluminium Plant and Vessel Company of Wandsworth, London. The Engineering School at the University of Melbourne, to which Dr. Burstall is going, is one of the largest in Australia, the students numbering nearly two hundred. During the last two years of the four year course the undergraduates specialize in either civil, mechanical, mining, electrical or metallurgical engineering before taking their degrees. Dr. Burstall succeeds Prof. Wilfrid Kernot, who is retiring in March at the end of the present academic year.

Ernst von Bergmann

Ernst von Bergmann, who was one of the most skilful surgeons and commanding personalities in Germany of the last century, was born at Riga on December 16, 1836. He received his medical education at Dorpat, Vienna and Berlin and qualified on November 13, 1860. He commenced his career as assistant in the Dorpat surgical clinic and afterwards served as a medical officer in the Prussian Army in the war with Austria in 1866 and in the Franco-Prussian war in 1870. He was elected professor of surgery at Dorpat in 1871. In 1877, when war broke out between Turkey and Russia, he became consulting surgeon to the Russian Army invading Rumania, and in the treatment of wounds carried out the antiseptic method just introduced by Lister. His activities as a military surgeon, however, were cut short by a severe attack of dysentery, and in 1878 he was appointed professor of surgery and senior surgeon to the Julius Hospital at Wurzburg. He remained there until 1882, when he succeeded Langenbeck in the chair of surgery at Berlin. In 1887 he attended the Emperor Frederick in his last illness, when an unfortunate dispute as to the correct diagnosis and treatment arose between the German surgeon and Morell Mackenzie, the well-known London laryngologist and author of "Frederick the Noble".

Von Bergmann is best known for his introduction of aseptic surgery, the principles and practice of which he described at the Tenth International Medical Congress held at Berlin in 1890 in conjunction with his assistant C. S. Schimmelbusch, whose work on the subject is a surgical classic. Von Bergmann also made a valuable contribution to the literature of military surgery by his works on injuries to the head and brain and gunshot wounds of the knee-joint. In association with Profs. von Bruns of Tübingen and Mikulicz of Breslau, he edited a handbook of practical surgery, of which the first edition appeared in 1900. He took an active part in the promotion of post-graduate study and was the founder and moving spirit of the Berlin ambulance organization. He was the recipient of many honours both in Germany, where he was given the title of Excellency and made a member of the Prussian House of Lords, and in other countries including England, where he was elected in 1900 an honorary fellow of the Royal College of Surgeons. He died at the age of seventy years on March 25, 1907, and was succeeded in the chair of surgery at Berlin by Prof. August Bier, who celebrated his seventy-fifth birthday on November 24.

Alexander Neckham (1157-1227)

In his Friday evening discourse at the Royal Institution on December 4, Sir Stephen Gaselee discussed "Natural Science in England at the End of the Twelfth Century". It was impossible to survey all the English writers who were treating of natural science about A.D. 1200, but there is fortunately one who was widely read and a good compiler, and at the same time a personal observer of Nature—Alexander Neckham, born in 1157. He was born at St. Albans; afterwards he was headmaster of a school at Dunstable, and also studied in Paris. He later joined the Augustinian Canons at Cirencester, where he spent the rest of his life, becoming their abbot in due course, and died about 1227. He was an author of many and various works: one is called "Of the Natures of Things", and is partly a compilation from Pliny, Solinus and Cassiodorus; but is not without evidence of his own personal investigations. There is continuous moralizing throughout the book; but in natural science he begins with a description of the firmament, the sun, moon and stars; then the four elements; and then starts a survey of the animal world, beginning with birds. He intersperses his scientific descriptions with anecdotes, sometimes amusing, as of those of the hawk and the eagle, the parrot, and the wren. Turning to fishes, he first refers to some of the physical properties of water and then describes the inhabitants of the deep with a story about the plaice: fishes finished, he describes minerals, with an interesting account of the properties of the loadstone, and vegetables: and then the animal kingdom, with amusing stories about weasels, monkeys and lions: and finally comes to the 'lord of creation', man; after a talk of light and mirrors, he describes the purports of the farm-yard and the dwelling house, with an interesting discussion on silk-worms, and incidentally mentions education and the universities of his day.

British Association: Officers for 1937

THE annual meeting of the British Association will be held next year in Nottingham on September 1–8 under the presidency of Sir Edward Poulton. The following sectional presidents have been appointed: Section A (Mathematical and Physical Sciences), Dr. G. W. C. Kaye; B (Chemistry), Dr. F. L. Pyman; C (Geology), Prof. L. J. Wills; D (Zoology), Prof. F. A. E. Crew; E (Geography), Prof. C. B. Fawcett; F (Economics), Prof. P. Sargant Florence; G (Engineering), Sir Alexander Gibb; H (Anthropology), Dr. J. H. Hutton; I (Physiology), Dr. E. P. Poulton; J (Psychology), Dr. Mary Collins; K (Botany), Prof. E. J. Salisbury; L (Education), Mr. H. G. Wells; M (Agriculture), Mr. J. M. Caie.

Peking Man: Further Discoveries

RECENT excavation in the cave of Choukoutien, the home of Peking man, has proved fortunate beyond all expectation. No less than three new skulls of *Sinanthropus* have been added to the relics of this primitive type of early man. On October 22, Mr. L. P. Chia, of the National Geological Survey of China, brought to light a left mandible with teeth pronounced to be male in type, to which Sir Grafton Elliot Smith refers in a letter to *The Times* of December 5. This was followed by the discovery by the same excavator of two skulls (*The Times*, Nov. 20) and to this in turn has succeeded a further discovery of another skull, which, if the description given in the dispatch from the Peiping correspondent of *The Times* of December 8 be accepted as accurate, may well prove of even greater significance than the earlier finds of new material. With the two skulls previously known, of which the first was found by Mr. W. C. Pei in December 1929, there are now five skulls of *Sinanthropus pekinensis* in existence, while a sixth has been reconstructed from fragmentary finds by Prof. Franz Weidenreich, the director of the Cænozoic Research Laboratory of the Geological Survey. The new material is of outstanding importance in view of the fact that the skulls are those of fully developed adults, whereas the two skulls previously known were those of adolescents. Of the skulls recently discovered, the first two are of a male and a female, in age between forty and fifty years. Added evidential value attaches to the third skull owing to the fact that it is in a more complete state of preservation than any previous specimen. Certain parts of the base of the skull missing in the other skulls are here present, as well as parts of the facial skeleton and nasal structure.

Significance of Peking Man

THE relics of Peking man available for study at the Peiping Union Medical College, together with the new skulls, represent twenty-four individuals, and include twelve lower jaws and nearly one hundred teeth. They fully justify the description of them by Prof. Weidenreich as the "richest and most complete collection of human fossils ever recorded, unique in every respect" (*The Times*, Nov. 25). Since Prof. Weidenreich's appointment to the Rockefeller Institute, constituting him Director of the Cænozoic Research Laboratory in succession to the late Dr. Davidson Black—an appointment made on the recommendation of Sir Grafton Elliot Smith, as the latter now reveals in his letter to *The Times*, where, however, by a clerical error the name appears as "Weideman"—he has naturally devoted much time and attention to the study of Peking man, and in a recent publication (see NATURE, **173**, 73) has put forward some interesting and suggestive conclusions as to the relation between *Sinanthropus* and Mongolian man, while further important results have accrued from his comparative studies based more particularly on the examination of the endocranial casts (NATURE, Oct. 17, p. 689). With this additional important material at his disposal, illuminating studies may be anticipated. While it is too early, and too little information is available, to attempt any forecast of the direction in which results are likely to tend, it is interesting to note that it is stated that the female skull has many similarities to *Pithecanthropus*, while the male skull is much higher and nearer Neanderthal man. Further, Prof. Weidenreich is reported to have said that the various specimens of Peking man form links between *Pithecanthropus* and Neanderthal man. Sir Grafton Elliot Smith's letter to *The Times*, relying on information supplied by Mr. W. C. Pei, now superseded, expresses some anxiety as to the future of these investigations. Clearly, in view of the importance of the material now awaiting examination, any serious interruption or even break in continuity would be a catastrophe.

British Launderers' Research Association

EXTENSIONS to the laboratories of the British Launderers' Research Association were opened by Sir William Bragg on December 1. Mr. W. H. Markham, chairman of the Association, mentioned, in his introductory remarks, that the recent extension of the basis of membership of the Association has met with a good response from the industry, and also that, with an increase of the maximum grant received from the Department of Scientific and Industrial Research, the income of the Association in the coming year will exceed £10,000. The Association, which was formed in 1921, early commenced a systematic investigation of each section of the laundry process. It instituted methods of measuring colour and observing the efficiency of cleansing on washed articles. Research work now in progress includes studies of the fundamentals of detergency, for example, an investigation of the physical properties of soap and alkaline solutions as well as those of the new detergents known as sulphonated fatty alcohols. Work is also proceeding upon engineering problems which are encountered in laundry machinery. The examination of plant, products and materials, of new and laundered fabrics, is a part of the routine work of the laboratories. In addition, an analytical department undertakes the analysis of products used by the launderers. The information gained is published in the form of reports to members, and a bulletin is issued quarterly in order to inform members of the work in progress, etc. The Association has published three books: "Control of Laundry Operations", "Chemistry of Laundry Materials" and, recently, "Technology of Washing".

Ancient Egyptian Sculpture

MR. C. S. GULBENKIAN's loan to the British Museum (Bloomsbury) of fourteen pieces of ancient Egyptian sculpture from his collection, for a period of eighteen months, which is now on view in the entrance hall, not only illustrates Egyptian art for a period of 2,000 years from the Middle Kingdom to Ptolemaic times, but it also serves to bring out in a marked degree certain characteristics in which the masterpieces of that art stand out, as against the products of the classical period, and in which it is, in fact, closely akin to the aims of certain schools of modern art. Egyptian art, and more especially Egyptian sculpture, when freed from the conventions imposed by the necessities of formal presentation for State or official purposes, showed a remarkable, and indeed an exceptional, ability to express character and individuality in portraiture. While this is generally admitted in the obvious instance of the Tell el-Amarna school under the influence of Akhnaton, which usually, though not invariably, emphasizes and idealizes a defect, it would seem, in preference to strength, it is equally true of the more robust tradition, which can be traced so far back as the Fourth Dynasty and produced, for example, such well-known specimens as the statuette of Khufu and the effigy of the "Sheikh ed-Beled". That this tradition persisted through a prolonged period can be seen in some of the later exhibits in the British Museum loan collection, such as, for example, the remarkable head of a man in green schist of the sixth century B.C., though possibly many may consider the gem of the collection to be the head in obsidian attributed as a portrait of Amenemhat III to the Twelfth Dynasty, in which the characterization is no less remarkable than the technical skill, which could subdue so refractory a material to its purpose. Another exhibit, in bronze, though of a different genre, attracts attention, and charms by its unusual subject—a cat with two kittens playing

Sir Robert Hadfield's Gift to Harvard

IN a supplement to the *Engineer* of November 20, there were reproduced photographs of four very striking water-colour drawings depicting war-time work in three departments of Messrs. Hadfields Ltd., of Sheffield. The artist, Mr. Herbert J. Finn, in these drawings, has succeeded in conveying in a remarkable manner the sense of intense activity and vibrant energy of the giant furnaces and myriads of whirling belts of an engineering shop, which may come to be regarded as characteristic of this machine age. Equally vivid, but of totally different character, is Mr. Finn's water colour "Oxford from the Sheldonian Theatre", a pictorial representation of Oxford's spires and domes—a vista breathing the peace and quietude of medieval England. Sir Robert Hadfield has acquired this picture and has presented it to Harvard University in connexion with the occasion of its tercentenary celebrations. Harvard's leading metallurgist, Prof. Albert Sauveur, himself an old friend of Sir Robert, is well known in British engineering circles, for he was the recipient in 1924 of the Bessemer Gold Medal of the Iron and Steel Institute; on the other hand, Sir Robert is probably equally well known on the west of the Atlantic, for he is a foreign associate of the National Academy of Sciences, he received the John Fritz Gold Medal of the United Engineering Societies of the United States in 1921 and the Elliott-Cresson Gold Medal of the Franklin Institute in 1901. Sir Robert's gift is not only a mark of his own respect and admiration for a great centre of learning in the United States, but also a further link between the universities of Great Britain and the New World, helping to hold them together in the ever-intensifying quest for knowledge.

The Parliamentary Science Committee

THE Council of the British Association resolved, at its meeting on Friday last, that the Association should become a constituent member of the Parliamentary Science Committee, and appointed as its representative Prof. Allan Ferguson, one of the general secretaries of the Association. The arrangement made is subject to revision after three years. The announcement will afford particular pleasure to the members of the British Science Guild, which has now been incorporated with the British Association. The Guild and the Association of Scientific Workers were the parent bodies of the Parliamentary Science Committee, which came into being in October 1933, almost immediately after the presidential address of Sir Frederick Gowland Hopkins at the Leicester meeting of the British Association.

Research Co-ordination Group

AT a meeting on December 2 at River Court, Hammersmith, London, W.6 of the Research Co-ordination Group (see NATURE of February 22, p. 311, and May 30, p. 898) a number of problems dealing mainly with (1) rise in the standard of living and (2) security, were suggested for the attention of scientific investigators. Among these were: the standardization and extension of statistical information, both as regards production and consumption; nutritional needs and national fitness; population problems and genetics questions; scientific agriculture, afforestation, land reclamation; regional distribution of industry; hydro-electric power, new industrial developments (light metals, carbide and acetylene, plastics, cellulose, synthetic fats); aircraft and poison gas defence; psychology and war; educational use of cinema; vocational outlet for trained workers; and several others. These are to be grouped around the various sciences to which they are related. The chairman (Sir Richard Gregory) referring to the fact that many of these problems have been discussed at recent meetings of the British Association, suggested that the closest co-operation be maintained with the Association, and it was agreed that, if possible, suggestions be made to recorders of suitable sections for the inclusion of such papers in the programme of the next meeting at Nottingham. Material on the above or other suitable topics should be sent to the Honorary Secretary, Research Co-ordination Committee, Hazlitt House, Southampton Buildings, W.C.2 (Telephone, Holborn 1713).

Relativity and the Quantum Theory

IN a lecture given before the Newcastle-upon-Tyne Astronomical Society on November 5, Prof. R. A. Sampson discussed "The Spectroscope in the Observatory". Remarking that the spectrum, along with Wilson's cloud chamber and photographs of diffraction patterns due to electrons, furnishes visible records of things that are too small to see, Prof. Sampson pointed out that Dirac holds it is quite impossible to make a rational theory of these things without reconstructing our ideas of the nature of matter altogether. This has led to the two great theories of modern times, namely, relativity and the quantum theory. They are not yet fully reconciled. In his opinion, there are considerable philosophical difficulties in holding either. Relativity, on its merits, may seem a probable theory, but it cannot do its feats without making time an equal co-ordinate with the familiar three of space. Now we cannot think time away, without sacrificing the possibility of expressing ourselves intelligibly to others, and living in a world where history and cause and effect have no meaning. Nor does it upset our own affairs alone; we see the grass grow in summer and die away in winter. That must be an illusion. It seems to Prof. Sampson a simpler hypothesis to suppose that the intellect is limited. The quantum theory, which is obviously on the right lines, makes in small matters an enormous logical difference, and gives a new meaning to the question "Will the sun rise tomorrow?"—for example, when we are dead, or last century, before we were born. We must confess that we have no means of verifying whether it does or not. It seems that both these theories spell the exhaustion of the constructs of the intellect, of which a necessary part is the four elements of space-time, which must be exhausted sooner or later. Leaving these philosophical questions, Prof. Sampson gave a description of the ordinary theory of stellar sequences, etc., including the Russell diagram of the relation of luminosity to spectral class, and white dwarfs.

Supervision of the Nation's Food Supply

IN the fifteenth Benjamin Ward Richardson Lecture which was delivered on November 10 before the Royal Sanitary Institute, Dr. Gerald Leighton, late Medical Officer of the Department of Health for Scotland, stated that from the public health point of view three conditions are required for the proper supervision of the nation's food supply. In the first place, there must be a concentration and collection at certain centres of large quantities of the food material, so that there may be adequate inspection. Although the necessity of this condition was recognized more than forty years ago by the United States Department of Agriculture, which established a well-regulated system of slaughter houses, Great Britain has been very slow in adopting the system of public abattoirs, the need of which was so strongly urged by Benjamin Ward Richardson himself. The second condition necessary for effective supervision is the supply of a sufficient number of highly trained inspectors. Great progress has been made in this respect during the last twenty years, training for students as meat inspectors being provided by veterinary colleges, some universities and other educational bodies. Lastly, a uniformity of system and practice is essential. The inspectors should be trained to work on a uniform system and to a uniform standard instead of, as in the old days, each inspector being a law to himself. Dr. Leighton then dwelt on the desirability of securing and adopting the most rapid, skilled and humane methods of slaughtering all kinds of animals for human food, a topic which formed part of the life work of Richardson. In conclusion, he expressed the view that in the progress of the supervision of a nation's food, the introduction of legal standards, as in most European countries, America and various parts of the Empire, for the majority of foods is the most important step for future development.

The London Telephone Trunk Exchange

IN a paper read on November 13 to the Students' Section of the Institution of Electrical Engineers, Mr. H. M. Wells discusses the effects of the rapid increase of the telephone service in Great Britain on the methods of working. The country is divided up into zone areas and subdivided into group areas. Major trunk lines connect main zone exchanges with London and with one another. They are so designed that a minimum of duplicate plant is necessary. By the use of thermionic amplifiers, the volume of speech fed into a line is made equal to the volume received at the far end. When things are properly adjusted, there is thus no loss of sound. One result is that the speech on the London-Moscow circuit is as good as that on a local London call. The insulation materials of the cables used are paper and 'air-space'. The 'air-space' is filled with carbon dioxide which possesses desiccating qualities and can be readily pumped out from the cable and replaced by fresh gas capable of restoring the dry atmosphere required to maintain a high insulation resistance. In the exchange itself, the type of apparatus employed is designed to permit calls to be completed on demand, that is, whilst the calling subscriber is held on the line. Timing the duration of calls is a problem which has received special attention. In the trunk exchanges, all calls are timed automatically; this obviates any error due to the human element, and, as the calls are expensive, this is very desirable. The particulars from the time-recording instruments, together with the called and calling subscribers' numbers, are entered on a ticket by the operator and circulated to a central pricing position. The circulation is effected by pneumatic tubes. The power for the exchange is derived from secondary cells of large capacity. A voltage of 50 is used for normal speech and apparatus purposes, but the signalling lamps on the switchboard are worked at six volts from an alternating current source.

Grading of Teak Squares

WITH the hearty co-operation of business firms, the Forest Research Institute at Dehra Dun has published a small pocket monograph entitled "Rules for the Grading of Teak Squares", prepared by L. N. Seaman, officer in charge, Timber Testing Station, and V. D. Limaye. In a preface, Mr. C. G. Trevor, Inspector General of Forests, states that the work was undertaken at the request of the Chief Conservator of Forests, Burma, and the Indian Railways, and the Burma forest officers were deputed to the saw mills of the five chief teak firms to observe and write down in tabular form all the defects in each teak square passed by the respective firms as belonging to different existing grades. The data so obtained were dispatched to Dehra Dun for analysis, and preliminary draft rules were drawn up by Mr. Seaman and his staff. These rules were discussed at a meeting held in Rangoon between the parties interested, and a trial was made of them. As a result of experience gained, the rules were re-written by Mr. Limaye (Mr. Seaman having left India on retirement) and are now published in the present handy form. The rules express, in so many words, the actual practice that is followed in the trade in the grading of teak squares. The rules have been accepted by the teak lessees of Burma and the timber adviser to the Railway Board and the Army. The rules are equally applicable to mill-sawn squares from Siam and other countries, and it is suggested that in future they will always be used for the buying and selling of teak squares.

Design in Industry

AT the opening meeting of the new session of the Royal Society of Arts on November 4, the chairman of the Council, Sir Henry McMahon, announced the institution of a new distinction of D.I. (Designer for Industry) for designers for industry who have attained eminence in creative design. The distinction is limited in the first instance to ten and the number of holders of it at any one time will not exceed thirty. The essence of the scheme is to encourage the improvement of industrial design by enhancing the status of the designer in the public regard, and thereby arousing a more general recognition of the importance of industrial art. This latest step is in continuance of the Society's efforts in this field from the eighteenth century onward, and is a natural development of the annual competition of industrial designs initiated in 1923 and of the Exhibition of British Art in Industry organized at Burlington House last year in co-operation with the Royal Academy. The very success of the Exhibition, which stimulated a widespread movement advocating the cause of art in industry, emphasized the fact that no recognition or distinction was heretofore available for designers, who through their great work for industry are deserving of wide public recognition of their valuable services to their country. This gap, it is hoped, will be filled by the new distinction.

The *Geographical Magazine*

THE completion of the second year of the *Geographical Magazine* directs attention to the value of its articles and the excellence of its illustrations, the photogravure and coloured plates in particular reaching a high standard. Among articles in the December issue is one by Dr. R. Zeller on the "Development of Alpinism in Switzerland" which is illustrated by a large number of old prints. In view of the modern vogue of alpinism, which the writer defines as an interest in high mountains and their exploration, it is worth noting that at least until the eighteenth century the Alps repelled travellers. The influence of two writers, von Haller and Rousseau, did much to direct attention to the Alps, but with a few exceptions there was little real mountaineering until Paccard and Balmat climbed Mont Blanc in 1786. Maps did not become available until the nineteenth century, and from the middle of that century onwards accurate maps and guide books were great stimuli to active alpinism, while the twentieth century may be said to have seen its popularization.

Demographic Statistics

ACCORDING to statistics recently published in Germany, the average duration of human life in most countries was about fifteen years longer in 1921 than in 1871. In 1880 in Germany, 261 out of 10,000 inhabitants died as compared with 212 in 1900 and 111 in 1930. During the same periods there were 205, 182 and 114 deaths in England, and 198, 176 and 113 in the United States. In Hungary the decline of mortality was most pronounced, there being 386 deaths per 10,000 inhabitants in 1880 and only 155 in 1930. During the same period of half a century, the percentage fall of mortality in different countries was as follows: Germany, 54·8; England, 44·4; France, 22·6; Italy, 41·7; Switzerland, 51·8; Sweden, 39·7; United States, 40·4; and Australia, 46·9 (*Bruxelles Méd.*, October 25).

International Congress for Applied Mechanics

THE fifth International Congress for Applied Mechanics will meet in Cambridge, Massachusetts, on September 12–16, 1938, at Harvard University and the Massachusetts Institute of Technology. The programme will cover three main divisions of applied mechanics as follows: (1) structures, elasticity, plasticity, fatigue, strength theory, crystal structure; (2) hydro- and aero-dynamics, gas dynamics, hydraulics, meteorology, water waves, heat transfer; (3) dynamics of solids, vibration and sound, friction and lubrication, wear and seizure. Further information can be obtained from the Secretary, Fifth International Congress for Applied Mechanics, Massachusetts Institute of Technology, Cambridge, Mass.

Announcements

PROF. G. I. TAYLOR will deliver the Christmas Lectures "adapted to a juvenile auditory" at the Royal Institution, 21 Albemarle Street, London, W.1 on December 29 and 31 and January 2, 5, 7 and 9. The subject of the lectures will be "Ships". Further information can be obtained from the Assistant Secretary.

THE following appointments and promotions in the Colonial Service have recently been made: Lieut.-Commander J. R. de la Haule Marett, to be assistant in ethnology, Colombo Museum, Ceylon; J. A. Richardson, to be field geologist, Malaya; F. J. Ryeland, to be inspector of mines, Gold Coast; J. R. Lockie (assistant conservator of forests, British Guiana), to be assistant conservator of forests, Nigeria; F. R. H. Green (inspector of mines, Kenya), to be superintendent of surveys, Lands and Mines Department, British Guiana; V. T. Hockin (assistant inspector of mines), to be inspector of mines, Tanganyika; S. Napier-Bax (senior field officer), to be assistant director, Tsetse Research Department, Tanganyika; Capt. A. T. A. Ritchie (game warden, Kenya), to be chief game warden, Federated Malay States; N. H. Vicars-Harris (assistant director, Tsetse Research Department), to be secretary of the Department of Lands and Mines, Tanganyika.

AN annual sum of about £30 is available from the Clough Memorial Research Fund, which was instituted in 1935 for the purpose of encouraging geological research in Scotland and the north of England (Northumberland, Cumberland, Westmorland, Durham and Yorkshire). Applications for grants are invited for the period April 1, 1937–March 31, 1938. Further information can be obtained from the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh.

PROF. FRIEDRICH ZAHN, president of the Bavarian Statistical Office, has been nominated president of the International Statistical Institute.

PROF. EMIL ABDERHALDEN, director of the Physiological Institute at Halle, has been nominated an honorary member of the Sociedad Cubana de Biologia.

VIENNA has the lowest birth-rate in the world; in 1935 there were only 7 births per 1,000 inhabitants. In March 1936, there were 978 births, of which 496 were males and 482 females, while there were 2,219 deaths, of which 1,123 were males and 1,096 females, so that in a single month the population fell by 1,243.

ERRATUM.—In the record of the award of the Darwin Medal of the Royal Society in NATURE of December 5, p. 980, for Edgar James Allen, read Edgar Johnson Allen.

IN NATURE of November 28, p. 914, it should have been stated that the Rev. Wm. Tuckwell's surviving daughters are Miss Gertrude Tuckwell and Mrs. Marian Ethel Grew; Lady Welch died three years ago.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Engineer in a War Department establishment at Sutton Oak, Lancs—The Chief Superintendent, Chemical Defence Research Department, 14 Grosvenor Gardens, London, S.W.1 (December 15).

Scientific officers (chemistry), junior scientific officer (chemistry or physics), assistants (Grades I, II and III—chemistry) in the Chemical Defence Research Department—The Chief Superintendent, 14 Grosvenor Gardens, London, S.W.1 (December 15).

Mechanical engineering designer in the Design Department, Royal Arsenal, Woolwich—The Under-Secretary of State (C.5), The War Office, London, S.W.1 (Quote Appts./9) (December 15).

Assistant lecturer in civil engineering in the City and Guilds College—The Secretary, Imperial College of Science and Technology, Prince Consort Road, South Kensington, S.W.7 (December 15).

Head of the Engineering Department of the North Staffordshire Technical College—The Clerk to the Governors, Town Hall, Hanley, Stoke-on-Trent (December 16).

Assistant in the Research and Technical Publications Section of the Air Ministry—The Secretary, Air Ministry, Adastral House, Kingsway, W C.2 (December 19).

Biochemist in the Royal Berkshire Hospital, Reading—The Secretary (December 31).

Research officer on the scientific staff of the Agricultural Research Council for work on coccidiosis—The Secretary, 6A, Dean's Yard, Westminster, S.W.1 (January 1).

Lecturer in mechanical engineering in the Derby Technical College—The Clerk to the Governors (January 4).

Physicist in the Research and Development Department of the Cambridge Instrument Co., Ltd., Cambridge.

Lecturer in pathology of the diseases of infancy and childhood in the University of Glasgow—Secretary of the University Court.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1018.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

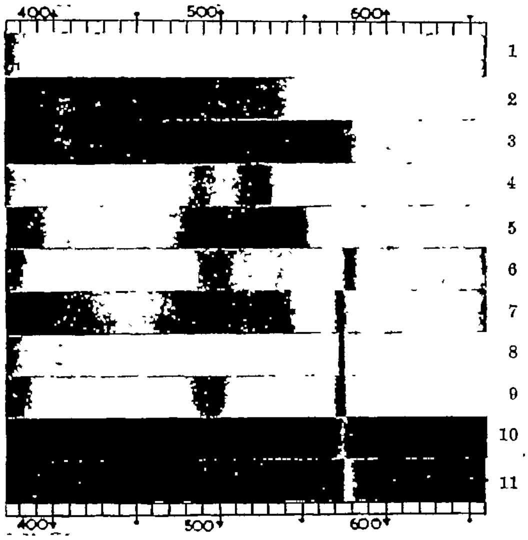
Spectral Absorption and Fluorescence of Dyes in the Molecular State

As Prof. R. W. Wood has stated on p. 648 of his "Physical Optics" (3rd ed.) that no liquid or solution has been found to exhibit the slightest trace of resonance radiation, it seems of interest to record that the effect has now been observed. It has been found possible to prepare suspensions of many dyes in solids and liquids, which possess an extraordinarily narrow absorption band associated with fluorescence of slightly longer wave-length. Three more or less general methods of preparation have been discovered, which possess the common feature that they cause the dye to pass from the dissociated state in true solution, through a transitory molecular state which exhibits a characteristic absorption and fluorescence, to the crystalline state. The effect is shown in a particularly striking manner by the dye 1 : 1′ diethyl-ψ-cyanine chloride, for which details of the three methods of obtaining the molecular absorption spectrum are given.

Method 1. A concentrated solution of 1 : 1′ diethyl-ψ-cyanine chloride in a strongly polar solvent, such as nitrobenzene or pyridine, was rapidly diluted with a non-polar or feebly polar liquid such as ligroin, carbon tetrachloride, benzene, toluene or xylene. The liquid became fluorescent and exhibited a very sharp absorption band having a maximum at λ=576 mμ. The position of the band was somewhat different for the different halides of the dye. Both the fluorescence and the absorption band rapidly disappeared as the dye passed into the crystalline state.

Method 2. The dye was dissolved in a fused strongly polar substance, for example, benzophenone, which was then crystallized by sudden chilling, whereby some of the dye remained molecularly dispersed in the solid. The position of the band depended on the particular salt of the dye, but did not seem to depend on the solid in which it was dispersed. It has been found that the sharp absorption band is not dichroic (not a function of the vibration direction), whereas absorption bands of crystals of the dye are strongly dichroic. This method is a general one for salts of basic dyes. The molecularly dispersed dyes slowly pass into a micro-crystalline condition, and the sharp absorption band disappears as this takes place.

Method 3. A solution of the dye in methyl or ethyl alcohol was added to 5*M* sodium chloride solution. The liquid became strongly fluorescent, and exhibited a very sharp absorption band at 574 mμ. The fluorescence consisted of a narrow band having a maximum intensity at 577mμ, which was excited almost entirely by the absorption band at 574 mμ. On heating the liquid to 60° the molecular absorption and fluorescence disappeared, and were replaced by the characteristic absorption spectrum given by the dye cations in alcoholic solution. On slowly cooling, the molecular absorption and fluorescence gradually increased in intensity, and the cation absorption correspondingly diminished. Similar reversibility was shown on varying the concentration of alcohol. A number of other dyes which have been examined behave in the same way, but the duration of molecular absorption may be anything from a fraction of a second to some weeks.



(1) Spectrum of tungsten arc lamp (containing neon).
(2) and (3) The two principal absorptions corresponding to the *X* and *Y* vibration directions of crystals of 1 : 1′ diethyl-ψ-cyanine chloride.
(4) Absorption spectrum of the dye in methyl alcohol.
(5) Absorption spectrum of the dye in nitrobenzene
(6) Absorption spectrum of a molecular suspension of the dye in toluene.
(7) Absorption spectrum of the dye molecularly dispersed in benzophenone crystals
(8) and (9) Absorption spectra of two different concentrations of the dye in sodium chloride solution.
(10) Fluorescence spectrum of the dye in sodium chloride solution.
(11) Fluorescence spectrum of the dye in sodium chloride solution. In this case the fluorescent light has been made to traverse a small thickness of unilluminated solution, so that the absorption band is seen superimposed on the fluorescence band. It will be noticed that the two do not exactly correspond.

On illuminating the fluorescent liquids with plane polarized light, the fluorescence was found to be unpolarized, showing that there is a time interval between the absorption and re-emission of light. The fluorescence is, therefore, visible when the liquids are examined between crossed nicols with a polarizing microscope. This is further proof that the fluorescence is a resonance effect, and is not light scattered by small solid particles of dye. It has also been noted that the dye in the molecular state shows a strong tendency to adsorb on the walls of the containing vessel, and in some experiments such adsorbed films showed the sharp molecular absorption band and associated fluorescence for a minute or so after their preparation, but the effect rapidly disappeared as the film passed into the crystalline state. Dyes adsorbed on filter paper, cotton wool, kaolin, etc., frequently possess an absorption maximum agreeing in position with the molecular band. This seems to indicate that some of the adsorbed dye is present in the molecular state.

A similar type of very narrow absorption band associated with fluorescence of approximately the same wave-length was discovered in the ruby by Ebert, and was examined in detail by Mendenhall and R. W. Wood. The ruby consists essentially of a crystal of aluminium oxide containing dissolved chromium oxide. The method of preparation of synthetic rubies corresponds in principle with the present method of producing the molecular absorption band of $1:1'$ diethyl-ψ-cyanine dispersed in a solid crystalline substance.

These phenomena are illustrated in the attached spectrograms which were photographed on 35 mm. Panatomic film by means of a grating microspectrograph described elsewhere[1].

The Beilby Layer on Non-Metals

IT is now generally accepted that the polish layer on metals is amorphous. The observations which led Beilby to formulate his famous conception of the vitreous nature of this layer were not, however, confined to metals, but had also been made with non-conducting crystals such as quartz, fluorspar, calcite and others. But Hopkins[1], working in G. P. Thomson's laboratory, has shown that the polish layer on Iceland spar cleavage faces is crystalline; and Raether's[2] electron diffraction patterns from polished natural faces of rocksalt, fluorite, calcite and pyrites are also wholly characteristic of crystalline structure. Nevertheless, the directness and simplicity of his experiments, in particular the exposure by etching of scratches eliminated by polishing, seem to speak convincingly in favour of Beilby's views.

Recently we have examined a wide variety of polished non-metallic single crystal surfaces, with results which go far towards reconciling the apparent conflict of evidence hitherto afforded by Beilby's microscope and the electron diffraction camera. Thus we have found that, whilst polished plane surfaces, cut in quite arbitrary directions from many types of single crystals (quartz, diamond, natural and synthetic sapphires, almandine and demantoid garnets, topaz, chrysoberyl, epidot, olivine, sphene, andalusite), yield electron diffraction patterns of spots and lines and thus provide irrefutable evidence of the crystalline structure of the polish layer on such surfaces, other crystals, notably white beryl, zircon, tourmaline, cassiterite and hæmatite, give the pattern of diffuse haloes more or less submerged in background which is so characteristic of liquid mercury, glasses, vitreous silica and of the amorphous Beilby layer. From other polished crystal facets (brown beryl, moonstone, orthoclase and cordierite) composite patterns were obtained in which the single crystal pattern showed faintly through that due to the amorphous layer. Spinels, both synthetic and natural, yielded either halo patterns or haloes and spots, only faintly distinguishable through the general background scattering. In some cases the structure of the polish layer appeared to be determined by the crystallographic nature of the facet examined. Thus one facet of a blue kyanite yielded a Beilby layer pattern through which single crystal spots were faintly distinguishable, whilst other facets of the same specimen gave single crystal patterns. Again, though the end faces of the prisms of a Zeiss nicol afforded quite good single crystal patterns, those from the junction faces were characteristic of the true amorphous Beilby layer. After etching, which revealed many coarse grinding scratches on all these faces, only typical single crystal patterns were obtained.

These results seem clearly to establish the validity of Beilby's view of the formation of the polish layer. That the layer is, however, often crystalline may be ascribed, except perhaps in the case of the diamond where polishing is possibly the effect of attrition alone, to a ready and spontaneous re-ordering of the molecules, disarranged by the act of polishing, in more or less strict orientation with those of the crystal matrix, whilst the amorphous nature of the polished surfaces of other crystal facets is evidence of the reluctance of the flowed layer to recrystallize; a reluctance which appears to be determined in some cases by the nature of the mineral, in others by the crystallographic direction of the polished facet.

Carborundum affords an example of a chemically formed amorphous polish layer. The untreated crystals, even though possessing perfect mirror-like surfaces, invariably yield typical Beilby layer patterns. Abrasion with fine emery paper (mainly rouge and aluminium oxide) or immersion in hydrofluoric acid appear to have no visible effect; nevertheless, after either of these treatments, carborundum flakes furnish single crystal patterns of quite exceptional clarity. Presumably the raw crystal surfaces are covered by a thin film of glassy silica formed by superficial oxidation during cooling of the charge[3].

An important result of these experiments is that the study of the diffraction of electrons by single crystals need no longer be confined to the often imperfect natural or cleavage faces. Any desired type of face can be exposed for this purpose by grinding and polishing, followed by etching in those cases where the polish layer happens to be amorphous. Finally, we have obtained good single crystal patterns from all over the curved surface of a short-focus plano-convex quartz lens. Thus every conceivable crystal plane should be accessible to the electron beam in a single crystal ground and polished as a sphere.

[2] Raether, *Z. Phys.*, **86**, 82 (1933).

[3] Germer, *Phys. Rev.*, **49**, 163 (1936), also obtained a halo pattern from carborundum and concluded that this vitiated the usual interpretation of the haloes obtained from polished surfaces; had he, however, removed the glassy film due to surface oxidation, a single crystal pattern would certainly have been obtained.

Scattering of Neutrons by Protons

THEORETICAL investigations of the interaction of protons and neutrons have been given by Wigner, Heisenberg and Majorana. A very valuable check on their conclusions is provided by the study of the scattering cross-section of the hydrogen nucleus for neutrons of various energies. Cross-sections have been measured for neutrons of low energies (a few volts) by Fermi and his collaborators[1]; for the photo-neutrons from heavy hydrogen (energy about 250 k.v.) by Goldhaber[2]; and for the neutrons obtained by bombarding carbon with heavy hydrogen (600–1,200 k.v.) by Tuve and Hafstad[3]. Dunning[4] also gives a value for the fast portion of the continuous spectrum of radon-beryllium neutrons, of which the average effective scattering energy probably lies in the region of 3–4 m.e.v.

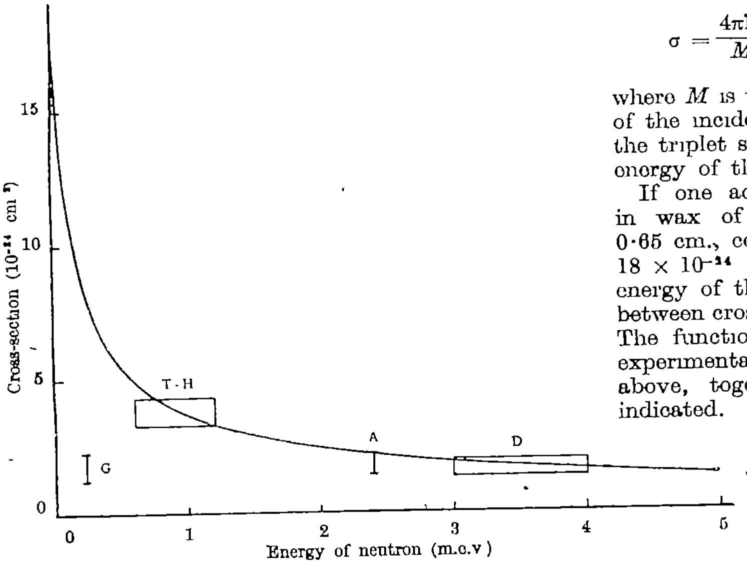

FIG. 1. The curve represents Wigner's theoretical neutron-proton scattering cross-section for neutrons of various energies. Experimental results of various investigators are also shown: G = Goldhaber, T-H = Tuve and Hafstad; A = Booth and Hurst; D = Dunning.

We have measured the cross-section of protons for the 2·4 m.e.v.[5] neutrons obtained from the D + D reaction. A fast neutron detector, consisting of an indium foil embedded in a block of paraffin wax 9·5 cm. × 5·5 cm. × 6·5 cm. was placed 23 cm. from the heavy phosphoric acid target. This detector was wrapped in cadmium foil to prevent so far as possible the entrance of any slow neutrons reflected from the surrounding walls: extraneous neutrons would tend to make the measured value of the cross-section too low. The scatterer consisted of a sheet of paraffin wax 7·7 cm. long, 4·8 cm. wide and 1·85 cm. thick. This was placed midway between the target and the detector. A thin packet of phosphorus, which responds only to fast neutrons, was placed near the target to enable a correction to be made for small variations in the intensity of the neutron source. The activities induced in the phosphorus and indium were measured on a Geiger-Muller counter.

Ten runs, five with and five without the scatterer, were made. After correcting for neutrons which were scattered and yet entered the detector, a free path of 4·6 ± 0·9 cm. was obtained for the neutrons in the wax. For the carbon correction, we adopted Dunning's value of $1{\cdot}7 \times 10^{-24}$ cm.^{2} for the scattering cross-section, for fast neutrons in carbon. After applying this correction we find a cross-section of $(1{\cdot}8 \pm 0{\cdot}4) \times 10^{-24}$ cm.^{2} for 2·4 m.e.v. neutrons scattered by protons.

A theoretical formula, assuming singlet and triplet states for the neutron-proton system, has been derived by Wigner. This gives the cross-section as a function of energy in the form

$$\sigma = \frac{4\pi\hbar^2}{M}\left[\frac{1}{4}\cdot\frac{1}{\varepsilon^1 + \frac{1}{2}E_0} + \frac{3}{4}\cdot\frac{1}{\varepsilon + \frac{1}{2}E_0}\right],$$

where M is the mass of the proton, E_0 is the energy of the incident neutron, ε is the binding energy of the triplet state (2·15 m.e.v.) and ε^1 is the binding energy of the singlet state.

If one adopts Fermi's value for the free path in wax of the DABI neutron groups, namely, 0·65 cm., corresponding to a cross-section of about 18×10^{-24} cm.^{2}, one can determine the binding energy of the singlet state and obtain the relation between cross-section and energy of incident neutron. The function is shown graphically (Fig. 1). The experimental results of the investigators mentioned above, together with our own value, are also indicated. The agreement between theory and experiment is satisfactory at the higher energies, but further experimental work seems to be needed in the intermediate region between 0·1 and 1 m.e.v.

A target of heavy ice cooled with liquid air has been installed since the above experiment was completed. As a consequence the neutron yield has been increased by a factor of five, and we hope to repeat the measurements using phosphorus as the neutron detector.

Inconsistency of the Neutrino Theory of Light

The neutrino theory of light proposed by Jordan[1] postulates a connexion between the quantized wave function of the light field (F) and that of the neutrino field (Ψ). Since Ψ satisfies the commutation rules for Fermi statistics and F those of the Bose statistics, the connexion cannot be a linear one. On the other hand, we know from quantum electrodynamics that F satisfies a linear differential equation; a similar equation of d'Alembert's type is to be expected for Ψ. Thus a contradiction arises between the linearity of the equations and the non-linearity of the connexion between F and Ψ. (This contradiction is avoided only in the case of plane waves propagating in one definite direction.) Besides, serious doubts arise as to the possibility of expressing the quantized amplitudes $b(\nu)$ for F (Bose statistics) in terms of the amplitudes $\gamma(\nu)$ for Ψ (Fermi statistics), the operators $b(\nu)$ and $\gamma(\nu)$ being of a quite different mathematical nature.

Jordan proposes[2] the following expression:

$$\sqrt{\nu}\, b(\nu) = \int_{-\infty}^{+\infty} \gamma^{+}(\alpha)\gamma(\nu+\alpha)\, d\alpha \qquad (1)$$

But it may be shown that the operators $b(\nu)$ so defined commute with one another as well as with the conjugate operators. In fact, applying the Fourier transformation from $\gamma(\alpha)$ to $\Psi(x)$, it is easily seen that (1) is equivalent to

$$\sqrt{\nu}\, b(\nu) = \int_{-\infty}^{+\infty} e^{-\nu x}\, \Psi^{+}(x)\, \Psi(x)\, dx \qquad (2)$$

The operator on the right-hand side has in configuration space of n particles (neutrinos) the meaning: multiplication by $\sum\limits_{k=1}^{n} e^{-i\nu x_k}$ and thus commutes with the conjugate one. The converse conclusion reached by Jordan is obviously due to some mistake in his calculations, most probably to the fact that he implicitly uses in his arguments indefinite expressions of the form $\infty - \infty$.

Since the relation (1) is the mathematical basis of Jordan's theory, the disproof of this relation entails the failure of the whole theory, at least in its present form.

From general arguments developed above, it is to be expected, however, that no consistent neutrino theory of light based on a relation between F and Ψ can be constructed.

Minimal Lines and Geodesics within Matter: a Fundamental Difficulty of Einstein's Theory

ACCORDING to Einstein's relativity theory *the minimal lines*, $ds^2 = g_{\iota\kappa}dx_\iota dx_\kappa = 0$, represent, in any circumstances (that is, in space-time upon which any metrical tensor $g_{\iota\kappa}$ satisfying the field-equations has been impressed), *light-lines*, and thus the laws of propagation of light. Now, *in vacuo*, the representation is of course correct, giving—apart from minor refinements—uniform, isotropic propagation with the velocity c, as pre-arranged. But inside matter, considered as a continuous medium characterized by the material tensor $T_{\iota\kappa}$, the minimal lines manifestly *cannot represent light propagation*, even to a rough approximation. For in such a medium, supposed isotropic, the light velocity is, essentially, c/μ (where μ is the refractive index, say, for light of a fixed frequency), whereas $T_{\iota\kappa}$, determining the $g_{\iota\kappa}$, contains no trace of μ, in fact, no properly optical feature of the medium in question. Thus, even without detailed mathematical deduction, one can see that, *within matter*, minimal lines are *not* light-lines; that is, $ds = 0$ does not represent light propagation.

To illustrate my point, let us consider the case of Schwarzschild's incompressible liquid sphere in equilibrium, that is, $T_1^1 = T_2^2 = T_3^3 = -p/c^2$, $T_4^4 = \rho$ (density) = constant, for which the complete solution is available. Take, for example, the case of purely radial propagation. Then, rigorously,

$$ds^2 = \frac{1}{4}\left(3\cos\frac{a}{R} - \cos\frac{r}{R}\right)^2 c^2dt^2 - dr^2,$$

where r is radial length in 'natural measure', $r = a$ the boundary of the sphere, and $R = c\sqrt{3/8\pi k\rho}$ the curvature radius of the manifold within the sphere (k = gravitational constant). Thus the minimal lines give for the velocity of propagation:

$$v = \frac{c}{2}\left(3\cos\frac{a}{R} - \cos\frac{r}{R}\right).$$

This velocity, then, is a curious function of the distance r from the centre of the sphere, but manifestly wrong. For of the properties of the medium, say, water, it contains only the mass-density ρ, through R. If $\rho = 0$, we have $R = \infty$ and the expression reduces to $v = c$, as it should. But this (absence of matter) *is the only case* when things are correct.

The net result is that within any material medium, as water or glass, Einstein's minimal lines express nothing of physical interest.

In much the same way, the *geodesics*, $\delta\int ds = 0$, which are claimed to represent the motion of free particles in any field $g_{\iota\kappa}$, have this property *in vacuo*, but not within a material medium. This may again be illustrated by Schwarzschild's solution, ds, for a liquid sphere as medium. The corresponding geodesic equations are readily written down, and they yield the following result.

If the Schwarzschild sphere is comparatively small (a/R a small fraction), a 'particle' placed in it at rest, at a distance r from the centre, is subjected, according to Einstein's theory, to an initial acceleration

$$E = -\frac{4\pi k\rho}{3}r,$$

towards the centre, no matter what the density (ρ_p) of the particle itself, whereas the (approximately) correct, Newtonian acceleration is, of course,

$$N = \frac{4\pi}{3}k\rho r\left(\frac{\rho}{\rho_p} - 1\right).$$

The Einsteinian acceleration E, as claimed by the geodesic, happens to agree with the Newtonian acceleration N when $\rho_p = \infty$, but in no other case. Of course, the correct acceleration would come out if we had supplemented the geodesic equations by the resultant of the pressures of the liquid upon the surface of the particle (Archimedes). But we are concerned here with the pure *geodesics* as characteristic lines of the four-dimensional manifold.

In fine, in the geodesic scheme, no account whatever is taken of the 'density' of the immersed test particle. The failure of the geodesics as representatives of motion within a material medium is quite analogous to that of the minimal lines, where no account is taken of the features of the immersed light, so to speak (namely, of its frequency entering into μ or into the dielectric constant of the medium). In fine, similarly to the minimal lines, the geodesics within matter express nothing of physical interest.

The whole part of Einstein's theory which claims to deal with the phenomena within material media would, then, have to be thoroughly rebuilt, which seems scarcely possible without entering into the granular structure of matter—a formidable task.

An Ecological Aspect of the Gulf Stream*

THE view has been increasingly accepted, since first put forth by Nathansohn[1], that the fertility of the sea depends upon the restoration to the surface of plant nutrients such as phosphates and nitrates liberated by the decomposition of organic matter within its depths. In shallow coastal waters the turbulence due to wind and tide, aided in high latitudes by the instability resulting from cooling in winter, suffice to maintain this part of the nutritional cycle. In the deep sea, organic matter generated in the surface as the result of photosynthetic processes appears in large part to sink to great depths before being finally oxidized to its ultimate inorganic products. This is evidenced by the increasing concentration of nitrate and phosphate (and decreasing quantity of oxygen) which is observed until depths of 800–1,000 metres are reached.

Wattenberg[2] has recently listed four processes by which these materials are brought again to the surface in the Atlantic Ocean and thus made available for the organic cycle. These are: (1) upwelling resulting from offshore trade winds off the African coast; (2) upwelling of deep Atlantic water in the Antarctic; (3) upwelling in the boundary between currents as in the Arctic polar front; and (4) winter convection in high latitudes. The present note is intended to direct attention to an additional and hitherto unrecognized mechanism which would appear to accomplish the same end and particularly to maintain the high fertility of the waters of the eastern coast of North America.

In a paper entitled "The Dynamics of Steady Ocean Currents in the Light of Experimental Fluid Mechanics", Rossby[3] has shown that the Gulf Stream may be likened to a wake stream discharging into the upper layers of a stratified medium. A wake stream, which appears to be a divergent current, is actually drawing in water from the surroundings. In a stratified medium the boundary between the layers must dip down towards the right in the northern hemisphere, as the isopycnics are observed to do in sections across the Gulf Stream, and this dip is to be regarded as the result rather than the cause of the current flow. The compensating movements set up in the surroundings of a wake stream must have a component in the direction of the current itself on the right side. The Antilles current appears to be such a compensating current. On the left side, the compensating movements must appear as a counter current, represented by the slope water of the American coast.

It is brought out that the absorption of water into the wake stream must take place primarily along the right edge, and that water will be ejected from the wake stream into the counter current. It results that water may be transferred across the current from the open ocean basins to the right into the limited body of water to the left of the current. This lateral transport must take place principally along isopycnics, which are known to slope sharply as they cross the Gulf Stream. Water is thus carried upward as well as shoreward as the result of the primary stream.

The observations of Seiwell[4] on the distribution of oxygen and phosphate in the north Atlantic make it clear that the apparent site of maximal decomposition of organic matter lies much closer to the surface (250 metres) in the continental slope water than in mid-ocean (800 metres). Such a large difference cannot reasonably be ascribed to differences in the rate of sinking or of decomposition of organisms in the contrasted localities. The findings are, however, entirely consistent with the wake stream theory developed by Rossby, since on this view the slope water is derived in considerable part from water absorbed at a greater depth along the offshore edge of the Gulf Stream. The close correlation which may be observed in a section across the Gulf Stream between the conservative properties of temperature and salinity, on one hand, and the properties of biological origin such as oxygen, phosphate and nitrate concentration, on the other, suggests that the observed distribution of the latter is the result of hydrographic factors rather than biological action *in situ*. The products of decomposition which appear at a depth of 200–300 metres in the slope water may have been actually derived from a much greater depth in the open ocean.

Rossby's wake stream theory thus provides a mechanism for the transport of water rich in organic nutrients from the depths of the Atlantic basin on to the edge of the continental shelf. Here it comes within the influence of tidal mixing and winter convection, which complete the transport of nutrients to the surface. The latter stages in the process may be observed in the Gulf of Maine, into which slope water penetrates, and along the continental shelf[5]. Rossby's study suggests that the absorption of oceanic water into the Gulf Stream takes place chiefly south of the latitude of Chesapeake Bay; the discharge of this water at a lesser depth occurs from Chesapeake Bay to at least Nova Scotia. If his theory is correct, he has discovered a mechanism on which the fertility of the waters of the Atlantic Coast of North America must largely depend.

Devernalization of Winter Rye by High Temperature

ALTHOUGH the effect of low temperature in inducing vernalization is now well established, it is by no means clear to what this effect is due. It appeared possible that the mere check in growth at low temperature is the chief factor. The results of Vasiljev[1], which showed that when the period of low temperature treatment is included the time taken to flower remains nearly constant, lends support to this view.

Experiments were therefore performed in which growth was checked by keeping the imbibed grain in an atmosphere of nitrogen for varying periods of time. At low temperature (1° C.) this may be extended to twelve weeks, and the seeds on exposure to air are viable and produce normal plants. They are, however, unvernalized. At 20° C. the seed does not remain viable if the continuous anaerobic period extends for more than three weeks. After such a period of checked growth, the further time required to flower is equal to that required by untreated plants.

It may therefore be stated that the check to growth is not the potent factor in vernalization, but that the effect must be attributed to the low temperature. This result also confirms the statement of Lysenko[2] that oxygen is necessary for the vernalization process.

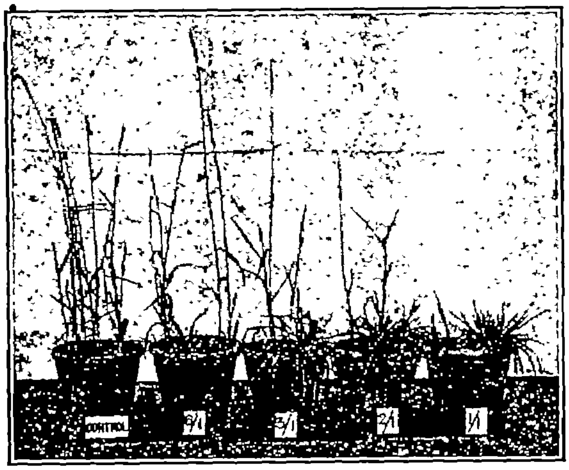

FIG. 1

By giving periods at 1° C. in air, alternating with periods in nitrogen at 20° C., it was possible to test whether high temperature can act antagonistically to low temperature. The alternating periods varied from six days in air at 1° C. followed by one day in nitrogen at 20° C., to one day in air at 1° C. followed by one day in nitrogen at 20° C., in each case the total period at 1° C. being six weeks. The controls were kept at low temperature continuously, but were in air and in nitrogen for alternate days for a total period of twelve weeks, thus also receiving six weeks of normal low-temperature treatment. The controls were all vernalized, whereas when the alternating periods in nitrogen were at 20° C. and of equal duration to the cold periods, vernalization was prevented. The results of four series with varying ratios of exposure to high and low temperatures are shown in the accompanying table.

Winter rye: total period at 1° C., six weeks in every case.

Treatment $\frac{\text{Duration in air at 1° C.}}{\text{Duration in N at 20° C.}}$	Days to anthesis from planting (average of those plants which eared)	Proportion of vernalized plants
1 . 1	unvernalized	None
2 : 1	106	20 per cent
3 · 1	99	60 ,, ,,
6 · 1	89	100 ,, ,,
Control	71	100 ,, ,,

The results show that high temperature negatives the effect of low temperature progressively as the relative period of high temperature is increased; further, this effect is not directly due to the anaerobic condition as the control experiments show.

Colloids and the Biological Effect of Radiation

IN a previous publication[1] I have pointed out that the problem of the primary process of the effect of radiation on living objects is a question of the action of rays on the different colloidal systems of the living cell. Therefore the question arises whether it is necessary to assume a special colloidal-chemical theory for the biological action of radiation.

The present investigation was undertaken to obtain information regarding the effect of ultra-violet light on colloids. Proteins, the most important colloidal constituents of the living cell, are of too complex a nature, and therefore difficult to study. As simple models, the ferric hydroxide sol (positively charged) and the negatively charged mastic and congorubin-red sol were therefore used; furthermore, I have studied the negatively charged gold and platinum sols, which were protected by decomposition derivatives of protein. These colloids are interesting models of bio-colloids. As source of light, a mercury vapour lamp was used. The exposures were made in water-cooled Petri dishes. The lamp was kept at a distance of 25 cm. above. The determination of the precipitating threshold of electrolytes (potassium chloride, hydrogen chloride, sodium hydroxide) was used as a test of the reaction to radiation.

The following results were obtained: (1) A completely negative result of irradiation in the precipitation of iron hydroxide sol; no visible change of the colour occurred, and no photo-chemical decomposition on measuring the pH by the electrical method of Michaelis. This completely negative effect agrees with the results of Burton[2] obtained with the electro-positive copper oxide sol. (2) The mastic sol demonstrates also no visible change, but a marked acceleration of electrolyte precipitation. This effect of irradiation outlasts the irradiation itself. An explanation of this phenomenon is only possible assuming a photo-chemical decomposition either of the particles themselves or the charging ions. (3) The irradiation of the congorubin-red sol effects a visible change of colour, making the photo-chemical decomposition of the particles very obvious. It was impossible, therefore, to precipitate the irradiated sol with electrolytes. (4) The irradiated gold and platinum sols demonstrate no visible change but a clear acceleration of electrolyte precipitation. Again this effect outlasts the irradiation itself. This effect points to a photo-chemical decomposition on the periphery of the particles, as photo-chemical decomposition of the particles themselves is not tenable. As these colloids were protected by decomposition derivatives of protein, the assumption appears permissible that the necessary photo-chemical action takes place in the protecting agents. This fact is of great importance in the examination of the action of radiation on bio-colloids, because many of them are known to be protected by light-sensitive substances.

Surveying these results, the following conclusions can be drawn: (1) The effect of ultra-violet light on colloids is purely a photo-chemical one. (2) The photo-chemical action can affect the particles themselves or their covering, for example, the protecting colloid, the charging ions. (3) The photo-chemical decomposition can cause a change of the electrical charge of the colloids corresponding to the electrical properties of the radiation, but it may also have just the opposite effect. (4) Where no photo-chemical action takes place, neither is there any change in the electrical charge. (5) In agreement with Nordenson[3] working with ultra-violet light and gold sols, and Annets[4] working with cathode rays and many positively and negatively charged colloids, it was found that the effect of irradiation is independent of the electrical charge of colloids. (6) It appears, therefore, unnecessary any longer to postulate a special colloidal-chemical theory of the biological action of radiation. (7) The photo-chemical theory of the effect of irradiation may also be applied successfully to the phenomena observed in different colloids after irradiation.

Oxygen Consumption of Mayfly Nymphs in Relation to Available Oxygen

LITTLE is known of the reasons why freshwater animals are confined to certain habitats, or of the effects of their particular environments on the metabolism of the animals. The first steps in a study of these questions were reported in NATURE, 130, 277 (1932). It has been shown that certain animals living in swift streams have a higher oxygen consumption and rate of heart beat than nearly related animals living in still waters, and that they are less resistant to water lacking oxygen[1,2,3]. The next step has been to study the oxygen consumption of such animals in terms of the available oxygen, and we have confined ourselves to mayfly nymphs. We have used *Baëtis scambus* and *Baëtis* sp. (the latter is one third the weight of the former) from a swift stream, *Leptophlebia vespertina* from Lake Windermere, *Cloëon dipterum* from a pond, and *Ephemera vulgata* living in mud in a pond. Our results are summarized in Fig. 1, in which the vertical line at an oxygen concentration of 7·9 c.c. per litre marks the oxygen content of water in equilibrium with the atmosphere at the temperature of the experiments, namely, 10°.

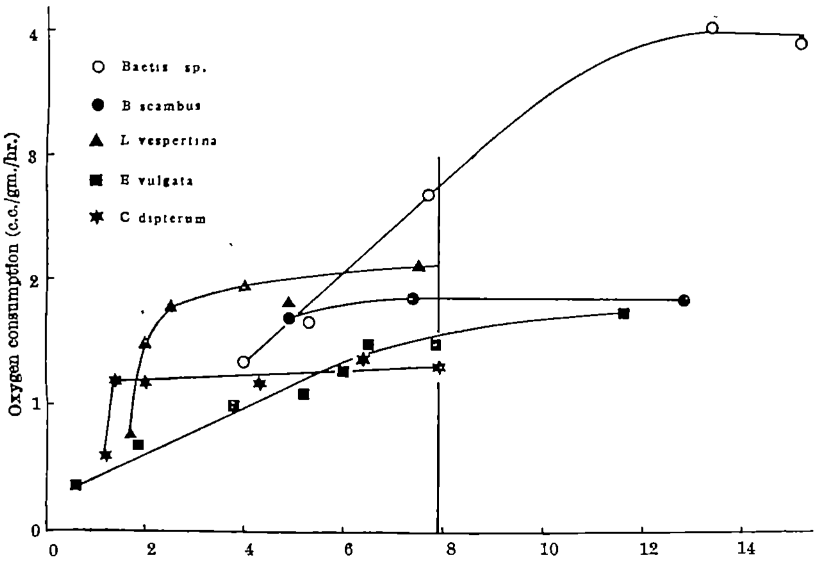

FIG. 1.

It is clear that *Baetis* sp. and *Cloeon dipterum* present extreme contrasts: as the available oxygen falls below air saturation, the oxygen consumption of *Baëtis* sp. falls off at once, while that of *Cloëon dipterum* does not decrease until the oxygen concentration is below one fifth air saturation. The oxygen consumption of *B. scambus*, which is much lower than that of *Baëtis* sp., decreases very little when the oxygen in the water diminishes. The oxygen consumption of *Ephemera vulgata* falls as soon as the oxygen in the water begins to decrease, but less rapidly than that of *Baëtis* sp. *Leptophlebia vespertina* recalls *Cloëon dipterum*: its oxygen intake falls slowly at first, and then, below one third air saturation, it drops suddenly.

As the oxygen in the water is raised above air saturation, *Baëtis* sp. increases its oxygen consumption until it has reached one and a half times its value in Nature, while, on the contrary, the oxygen intake of *Baëtis scambus* remains steady, and that of *Ephemera vulgata* scarcely rises.

It is evident that the species most dependent on the oxygen in its environment is *Baëtis* sp., and it lives in streams where oxygen is always abundant. *Cloëon dipterum*, the most independent form, was taken from a pond in which the oxygen falls low at night in summer. But if the behaviour of these species fits their environments, that of *Ephemera vulgata* apparently does not do so, for it was found buried in mud in a pond, yet its oxygen intake drops as soon as the oxygen in the water decreases.

These results will be published in full in the *Journal of Experimental Biology*.

Diastase in Rabbit Saliva

IT is frequently stated in general zoological literature that rabbit saliva contains an enzyme capable of hydrolysing starch to sugar. There is, however, so far, very little published experimental work to substantiate this statement. In fact, Schwartz and Rasp[1] were of the opinion that it was doubtful whether rabbit saliva contains a starch splitting enzyme of any kind. The low diastatic activity which they estimated, they were inclined to attribute to enzymes inherent in the food of the animal. Dukes[2] accepts this statement in a summary of recent work on the physiology of digestion.

Schwartz and Rasp, estimating the diastatic value by the production of achroodextrin from starch, reported that rabbit saliva (quantity unstated) would hydrolyse 2 c.c. of a 1 per cent starch solution in times varying from 50 to 81 minutes with an average of 68 minutes. I have been able to obtain complete hydrolyses of the same volume of starch solution in times varying from 30 seconds to 7 minutes. This marked difference in results seems to arise from the method by which the saliva is obtained from the animal. Schwartz and Rasp procured the secretion by placing in the rabbit's mouth a small wad of cotton wool which absorbed any free saliva in the mouth cavity. This was then placed in the given quantity of starch solution. I have been able to obtain the saliva by a suction method directly from the mouth, the fluid being collected in a small glass vessel. In this way, up to 0·3 c.c. can be procured in 3–5 minutes. I have also demonstrated that by placing a shred of cotton wool in the saliva so obtained, its activity is very considerably impaired. The low diastatic activity observed by Schwartz and Rasp, then, seems to lie in the fact that the enzyme is readily adsorbed by the cotton wool and so removed from the sphere of activity.

Work is at present in progress to try to account for the marked fluctuations in reaction time observed with saliva obtained by the suction method.

Rabbit saliva, like human saliva, has no effect whatsoever on uncooked or unbroken starch grains, owing to the resistant sheath of amylopectin in which the individual grains are enclosed. Work done by Pozerski[3] (1927) suggests that only a very small percentage of the grains are broken in the process of mastication. This brings to light the rather interesting problem of the possible utility of the enzyme in rabbit's saliva.

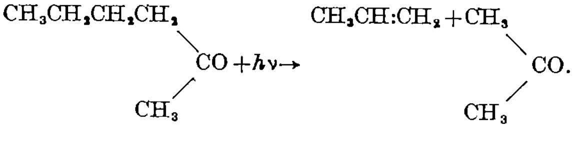
Photodecomposition of Aldehydes and Ketones

WE have recently extended our study of primary photochemical change by an investigation of the photodecomposition of the homologues of acetone in cyclohexane solution. It has been shown that in the gas phase there are two main types of decomposition. Type I occurs in short-chain aldehydes and ketones, and consists of an elimination of carbon monoxide, and the formation of an approximately equivalent amount of saturated hydrocarbon, resulting from the primary rupture of one of the carbonyl bonds; for example, in the case of acetone at 60° C. we have[1,2,3,4]:

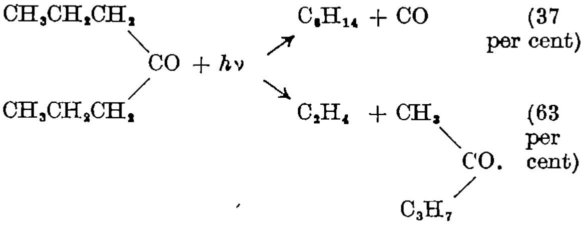
$$\begin{aligned} CH_3COCH_3 + h\nu &\rightarrow CH_3CO + CH_3 \\ CH_3CO &\rightarrow CH_3 + CO \\ 2CH_3 &\rightarrow C_2H_6. \end{aligned}$$

Type II, on the other hand, may be described as a species of cracking of the hydrocarbon chain in the $\alpha - \beta$ position to the carbonyl group, with the production of an olefine, and occurs increasingly with the higher homologues[2,5].

Thus with methyl-*n*-butyl ketone we have:



It has been shown that some carbonyl compounds in the gas phase decompose simultaneously in the two ways. This is the case with di-*n*-propyl ketone, in which both types have approximately equal probabilities of occurrence:



In solution and in the liquid state these results are considerably modified. Liquid acetone and acetone dissolved in benzene show no reaction whatever. In cyclohexane solution, however, as has been shown by Bowen[6], some reaction occurs with the solvent. Thus Type I decomposition is completely suppressed, and the excited molecules first formed must persist long enough to be deactivated by collision, or for reaction with the solvent.

With 10 per cent solutions of methyl-*n*-butyl ketone and di-*n*-propyl ketone in cyclohexane, however, at 20° C. we find a steady evolution of gas—practically pure propylene in the first case, and 98 per cent ethylene in the second, while in the irradiated solution of methyl-*n*-butyl ketone we have detected the presence of free acetone. It is therefore clear that while photodecomposition of Type I is almost completely suppressed, decomposition of Type II continues apparently unabated in solution. This is particularly apparent in the case of di-*n*-propyl ketone, in which both types occurred nearly equally in the gas phase.

At temperatures of *c.* 100° C., on the other hand, we have found that decomposition of Type I can also readily occur. For example, while pure liquid di-*n*-propyl ketone at 20° C. gives 98 per cent ethylene, at 90°–95° C. it gives a mixture consisting of *c.* 61 per cent ethylene, 30 per cent carbon monoxide and 9 per cent of ethane. At the same time the absolute amount of reaction according to Type II appears to be approximately independent of temperature.

It may be concluded from these results that:

(*a*) The mechanism of Type II decomposition is entirely separate from that of Type I.

(*b*) Molecules of the carbonyl substance can be activated in two alternate ways. In the first case (Type I), the excited molecule has a comparatively long life and is subject to strong deactivation by collision with the solvent, but the probability of reaction increases with temperature. In the second case (Type II), the time between excitation and reaction is so short as to be comparatively uninfluenced by the solvent molecules.

A Novel Interrelationship in the Triterpene Group

WE have elsewhere described the isolation of a diethenoid alcohol, $C_{30}H_{50}O$, accompanying β-amyrin and lupeol in the non-saponifiable fraction of shea nut oil[1]. We have now found that this alcohol, for which we propose the name basseol, is very readily cyclized by a variety of reagents to β-amyrin. This reaction is, we believe, the first example of the conversion of a naturally occurring tetracyclic triterpene to a likewise naturally occurring pentacyclic triterpene. It is of considerable biological importance in that it supplies an experimental realization of one stage in the natural evolution of a pentacyclic triterpene from presumably an acyclic structure of the squalene type by means of stepwise cyclizations.

A full account of this investigation will be published shortly.

Radio Fadings and Bright Solar Eruptions

WITH reference to the three recent large sunspots reported in NATURE of December 5, p. 965, it is of interest to note that on December 3 a bright hydrogen eruption was observed at the Royal Observatory, Greenwich, to take place near one of them which was at the time 55° west of the sun's central meridian. The region in question was under observation with the spectrohelioscope (using the hydrogen line of the solar spectrum, $H\alpha$) at $11^h\,46^m$ U.T., when a minor bright eruption was seen to be in progress. At $11^h\,57^m$ a recrudescence of activity began, and by $12^h\,03^m$ the bright hydrogen eruption had become as bright as the continuous spectrum 4A. from the centre of the $H\alpha$ line. At $12^h\,18^m$, cloud unfortunately intervened, but from previous experience it is known that the average duration of the major bright eruptions is 30–45 minutes.

The chief interest of the present solar eruption is that a marked abnormality in the ionosphere affecting radio transmission was reported to the Royal Observatory as having occurred on the same day from $12^h\,12^m$ until $12^h\,42^m$.

In a memorandum issued by the Astronomer Royal on December 1, it is pointed out that, from a preliminary comparison of twenty-three marked radio fadings and bright solar eruptions recorded during the twelve months, July 1, 1935–June 30, 1936, eight radio fadings occurred during the actual observation of bright eruptions on the sun. In addition, two fadings occurred when a bright eruption was listed as having been seen some minutes later to be already in progress, although its time of origin was not observed owing to cloud or some other circumstance. Of the remaining thirteen radio fadings, in one case the sun was not under observation at the time, and in twelve cases it could not be ascertained from the international solar data (published in the Zurich solar *Bulletin*) whether any solar eruption was observed at the respective times—the sun being actually under observation—or whether, owing to cloud, observations were impossible.

The memorandum proceeds to point out that since nine or ten marked radio fadings were closely associated in time with bright solar eruptions (the expectation of chance coincidences being less than two, if solar eruptions of all intensities be considered and almost negligible if the proportion of the more intense solar eruptions, appropriate to the twenty-three radio fadings, be taken into account), a definite correlation is suggested between the two phenomena, the relationship appearing to depend on a rapid transmission of some solar agency travelling with a speed approaching that of light.

It is suggested that in future the published international solar data should be still further extended, so as to provide the additional information as to whether at the time of any marked radio fading the sun was actually under observation at one or more of the observatories equipped with spectroheliographs and spectrohelioscopes.

Natural Selection

IN reply to Prof. MacBride's letter in NATURE of November 21, p. 884, may I just say that, both by my distinguished predecessor and myself, the study of as many specimens as possible has been recognized as of the first importance, and that is done not only at Oxford but also by visits to the British Museum (Natural History) and to Lord Rothschild's wonderful collection at Tring: indeed I was there yesterday.

The study of geographical variations, as we have so often emphasized, plays a leading part in the subject of mimicry; and, to paraphrase my friend's words, if he really wishes to know how the evolution of a mimetic pattern proceeded, let him come to the museum at Oxford. There he will see hundreds of *Papilio dardanus*, and all stages of evolution of the sundry mimetic tail-less forms of female from the tailed, male-like form.

I do not attempt to meet Prof. MacBride's arguments about mutations because, as I said in NATURE of October 17, they should be answered by more competent hands than mine.

Professional Associations of Scientific Workers

THE leading article in the issue of NATURE dated November 14 directs attention to the limited scope of most professional associations of scientists and emphasizes the need for one which concerns itself with the social aspects of science. The Association of Scientific Workers has for many years tried to fulfil this function, as reference to its policy will show. "The main objects of the Association are to promote the interests of the Scientific Worker and to secure the wider application of science and scientific method for the welfare of society."

It must not be thought that the Association believes that society is likely to be ruled by 'technocrats' in this or any other country in the near future. Political power is wielded by dictators and by organized masses, but not by professional associations. Even so, as NATURE asserts, scientists have an important contribution to make to the government of our country, and the Parliamentary Science Committee is a live expression of the holding of this belief by many scientists. The Association has played a large part in the formation of this Committee, which now speaks on behalf of 100,000 supporters in its constituent bodies.

Attention to the influence of science in national affairs and its bearing on current legislation is one aspect of the Association's work. In its other functions it is more like other professional associations which dislike the name trades union; like both, it takes an active interest in the conditions of employment and security of tenure of scientific workers of all kinds—it has often been able to assist individual members in cases of unfair treatment. Because of the general character of the work done by the Association, we feel justified in seeking your courtesy in publication. At the same time, we wish to urge all who would see science properly applied to get in touch with the Association and either join it or give it financial support.

W. A. WOOSTER.
Hon. General Secretary.

South Kensington,
London, S.W.5.

Points from Foregoing Letters

DR. E. E. JELLEY finds that certain dyes exhibit a characteristic absorption spectrum associated with fluorescence of slightly longer wave-length, on precipitation from their solutions, before they become crystalline. He considers that they are then in a molecularly disperse state. The author describes the preparation of such disperse systems of a ψ-cyanine dye in both liquids and solids. They show an unusually narrow absorption and fluorescence band, analogous to that of the ruby.

Prof. G. Ingle Finch reports that whilst polished surfaces of single crystals of certain substances (quartz, diamond, sapphire) yield electron diffraction patterns of spots and lines characteristic of crystalline structure, polished surfaces of other crystals (zircon, tourmaline, cassiterite) give patterns of diffuse haloes typical of liquid mercury and various glasses. Etching removes the amorphous polished layer and restores the crystalline pattern. This, the author considers, supports Beilby's view of an amorphous layer of polish which, however, may afterwards recrystallize.

The mean free path of neutrons of 2·4 m.e.v. in paraffin wax is found by E. T. Booth and Dr. C. Hurst to be $4 \cdot 6 \pm 0 \cdot 9$ cm., which corresponds to a scattering cross-section of $1 \cdot 8 \times 10^{-24}$ cm.^{2}. This value together with the neutron-proton cross-sections found by other investigators, for neutrons of different energies, is compared with the theoretical scattering curve derived from Wigner's formula.

V. Fock finds a contradiction in Jordan's neutrino theory of light, owing to the linearity of the equations and the non-linearity of the connexion between F, the quantized wave function of the light field, and Ψ, that of the neutrino. He considers, moreover, that no consistent theory of light can be constructed based on a relation of F and Ψ.

A difficulty in Einstein's theory when applied to phenomena within material media is discussed by Dr. L. Silberstein. Both the minimal lines which represent laws of propagation of light, and the geodesics which give the motion of a free particle in a field, are applicable, according to Dr. Silberstein, only in the absence of matter.

Dr. A. C. Redfield states that a theory proposed by Rossby concerning the Gulf Stream and its associated counter currents provides a mechanism for the transport of water rich in organic nutrients from the depths of the Atlantic basin, on to the continental shelf of North America, thus accounting for the fertility of the water of this region.

Prof. F. G. Gregory and O. N. Purvis report that winter rye is not 'vernalized' at low temperature (1° C.) if oxygen is excluded; also that seeds can be 'devernalized' by keeping them at a temperature of 20° in nitrogen for a period equal to that which they have been exposed at the low temperature.

The effect of ultra-violet light upon the stability of several colloidal systems (sols of ferric hydroxide, mastic, etc.) has been investigated by F. Ellinger. The author enumerates some of the results obtained which, he considers, bear upon the question of whether a special colloid-chemical theory is necessary to explain the biological action of radiation.

The oxygen consumption of various species of mayfly nymphs has been studied by Prof. H. Munro Fox, C. A. Wingfield and B. G. Simmonds, in relation to the amount of oxygen in the water. In some species the oxygen intake does not diminish until the available oxygen has fallen to a very low value; in others it decreases as soon as the environmental oxygen drops. In the presence of more oxygen than is available normally in Nature, the oxygen intake of one species rises as high as 1½ times its normal value.

That the rabbit saliva has the power of changing (broken) starch grains to sugar is confirmed by I. M. Thomas. He states that Schwartz and Rasp had failed to prove this conclusively because they had used cotton wads to collect the saliva, with the result that the enzyme responsible for the hydrolysis of the starch was adsorbed and rendered ineffective.

The chemical action of light upon compounds belonging to the acetone series, in cyclohexane solution, is found by Dr. R. G. W. Norrish and C. H. Bamford to be of the 'cracking' type only (leading to the formation of unsaturated hydrocarbons like ethylene), while in the gaseous state the same compounds under the action of light yield, in addition, saturated hydrocarbons like methane. The authors suggest an interpretation of these results based upon the length of life of the 'excited' molecules.

Research Items

Palæolithic Site in Manchukuo

PALÆOLITHIC artefacts excavated at Ho-Chia-Kou in Ku-Hsiang-Tung in the environs of Harbin, Manchukuo, by the Japanese First Scientific Expedition to Manchukuo, 1933–34, have been described by Shigayasu Tokunaga and Nobuo Naora (Report: Section 6, Anthropology, Pt. 2. Waseda University, Tokyo). The deposits had been much eroded by river action, which had exposed clay, now being used for making bricks, and fossil mammalian remains. The site was excavated by members of the expedition in 1933 and 1934. At a depth of 1–3 m. below the surface were found numerous fossil mammalian and plant remains, as well as artefacts coeval with the fossil remains. This account deals only with the artefacts. A notable feature of the culture of the site is the great preponderance of bone artefacts; 262 artefacts were unearthed, of which 24 were stone, 217 bone, 4 horn, and 11 tusk. A large quantity of charcoal was found, which may have served for fuel. There were also hundreds of animal bone pieces. The types represented in the stone implements were the willow type, the triangular type and the scraper type. The workmanship is generally rough. Though there are indications that some of the implements may have been manufactured locally, there is no material available within fifty kilometres of Harbin. The implements resemble the Far Eastern series which has been found at the base of the loess at Ordos and Shansi, and belong to the culture of the Loess period, which Boule, Breuil and others regard as either Mousterian or Aurignacian. They are, however, decidedly oriental. The bone artefacts include sixteen forms, among which are spear-head shape, harpoon shape, chisel, chopper, bowl, spoon, arrow-head shape, axe, wedge, etc. There are edged tools made from an animal pelvis, and a bowl-shaped artefact made from a deer's cranium. The tusk implements are all of mammoth ivory. Several walnut fruits were found.

Physiological Effects of Pressure

A USEFUL review of the researches on the physiological effects of pressure is provided by McKeen Cattell (*Biol. Rev.*, Oct. 1936). It is restricted to hydrostatic pressure transmitted to a tissue or organism completely immersed. Pressure applied locally on a part or by means of a gas introduces further complications, and so is not considered. The principal effects are reduction in volume, alteration in the velocity of chemical reaction and changes in viscosity. Other effects include changes in solubility, ionic dissociation and surface tension. In view of the incompleteness of our knowledge, generalizations can scarcely be drawn. It does seem, however, that relatively small pressures speed up physiological processes, perhaps in part due to the fact that decrease in volume involves a diminution in the spaces between molecules and a consequent increase in the collision rate between the reactants. Higher pressures bring about depression of activities and finally an irreversible polymerization of proteins and allied substances, and also the inactivation enzymes, toxins, antibodies and viruses. There is apparently a pressure-time threshold varying widely with different tissues or organisms below which the changes induced by pressure are reversed with decompression but above which the changes are irreversible. It is suggested that pressure, because of the ease with which it can be applied and controlled, may be a valuable aid in attacking physiological problems.

Distribution of Coast Gorilla

IN describing four gorillas from the Sanga River region, collected by the George Vanderbilt African Expedition of 1934, Harold J. Coolidge, jun., discusses the question of the distribution of the species (*Proc. Acad. Nat. Sci. Philadelphia*, 88, 479; 1936). In contrast to the opinion of Dr. A. H. Schulze, he regards the mountain gorilla as a race (*Gorilla gorilla beringeri*) distinct from the coast gorilla (*Gorilla gorilla*); and as collateral support of this point of view, he instances the discontinuous distribution of the two forms. There would appear to be a forest belt, 650 miles broad, stretching from long. 17° E., the eastern limit of the known range of the coast gorilla, and long. 28° E., the western limit of the mountain gorilla, in which gorillas are absent. For although various statements have been made of the presence of gorillas in this area, critical examination of the records shows that, with the exception of four skulls collected in 1908 from Bondo on the Uelle River, no great importance can be attached to the evidence. The lack of evidence is the more striking when account is taken of the fact that no record has been forthcoming during the last thirty-five years of active hunting and exploration in this part of the Congo.

Morphology of Coleoptera

IN the *Smithsonian Miscellaneous Collections*, 94, No. 13 (1936) are two papers of special interest to students of this order of insects. Mr. W. H. Anderson, of the University of Maryland, contributes a comparative study of the labium in Coleopterous larvæ. In this paper special stress is laid upon the origins and insertions of the labial muscles and their importance in determining the homologies of the parts concerned. The composition of the labium is described in representatives of many of the more important families, and what is regarded as its typical formation is seen in the larvæ of *Byrrhus* and *Silpha*. The second paper is by Mr. Richard E. Blackwelder, of Stanford University, who discusses the adult morphology as displayed in the family Staphylinidæ. Practically all the exoskeletal parts are described and figured from representatives of ten out of the fifteen subfamilies. A comprehensive study within the limits of a single family, as in the present case, merits the attention of systematists as well as morphologists, and a number of anatomical parts are dealt with which present available characters of possible importance for taxonomic purposes. Both the above papers are well illustrated and provided with useful lists of the special literature concerned.

Genetical and Taxonomic Investigations in *Œnothera*

THE importance of combined cytological, ecological, genetical and taxonomic research is slowly but surely becoming recognized by botanists. A paper by Prof. R. Ruggles Gates in which field, cultural, and, to a less extent, laboratory investigations are combined, has recently appeared (*Phil. Trans. Roy. Soc. Lond.*, B, 226, 239–355; 1936) and is doubly welcome for the results given and as a further example of improving taxonomic methods. The paper is concerned mainly with the results of field investigations of *Œnothera* populations made in eastern Canada in 1932, and with the detailed analysis of the cultures raised from the seeds collected. Seventeen new species and fifteen new varieties are fully and carefully described and figured. Valuable notes are given on the ecology, genetical peculiarities, behaviour under cultivation, and, for some of the cultures, the cytology. Such studies have enabled the author to indicate south to north movements in several different lines, epharmonic responses to environmental conditions, and evanescent characters which appear only during a part of the flowering season. That the catenation of all the plants dealt with in the paper and cytologically investigated was found to be, without exception, a ring of 14 chromosomes, may be considered further evidence that the genus *Œnothera* is cytologically exceptional among plants. Nevertheless, the suggestions made as to the causes of the polymorphism found in Eastern North America also apply, with certain modifications, to other genera. Gene mutations are said to have been active in supplying the raw materials for specific differentiation. Crossing has also probably played a part in increasing the number of specific types, the hybrids breeding true because of catenation. Such new 'constant' types are morphologically of equivalent value to the older species. Parallel mutations have also occurred many times in the different species.

Virus Diseases and Cytology

Two short papers by Dr. F. M. L. Sheffield (*Ann. App. Biol.*, 23, 498 and 506; August 1936) consider the reactions of host-plant cells to attack by virus disease. The first paper confirms some earlier experiments by Prof. B. M. Duggar, that the spraying of virus extract upon an unwounded plant did not result in entrance of the virus. Actual injection of an infectious liquid into single cells only resulted in about ten per cent infection, thus suggesting that all cells of the host are not equally susceptible to virus attack. The second paper shows that virus does not produce inclusion bodies in the guard cells of a leaf of *Solanum nodiflorum*, though these bodies may appear in every cell over large areas of the epidermis. This fact has now been correlated with the absence of protoplasmic connexions between the epidermal and guard cells, thus providing circumstantial evidence that the spread of virus from cell to cell is along the plasmodesma.

Irish Fungi

DR. P. O'CONNOR has published a "Contribution to Knowledge of the Irish Fungi" (*Sci. Proc Roy. Dub. Soc.*, 21, No. 39; Sept. 1936). He has paid most attention to the rusts and smuts, the Ascomycetes, Phycomycetes and Fungi Imperfecti, but the Aphyllophorales, the Exobasidiales and Auriculariales of Rea's classification of the Basidiomycetes have also received attention. Nearly 350 species are recorded, frequently from numerous localities; the kind of spore produced by rust fungi is noted, and host plants are also listed. Several fungi are cited as new to the Irish flora, whilst *Cicinnobolus Plantaginis* on *Plantago maritima*, *Septoria Rubiae* on *Rubia peregrina*, *S. Saxifragæ* on *Saxifraga spathularis*, and *Rhabdospora lentiformis* on ash, are new to the fungus flora of the British Isles.

Alkaline Rocks of Chilwa, Southern Nyasaland

AT the meeting of the Geological Society of London on November 4, Dr. Frank Dixey delivered a lecture on the alkaline rocks occurring in the vicinity of Lake Chilwa. The types described comprise the following: syenite; volcanic vents infilled with carbonates and brecciated felspar-rock; hydrothermal rocks in the vents; nepheline-syenite; and swarms of associated dykes of solvsbergite, microfoyaite, phonolite and nephelinite. The period of activity is ascribed to about the end of the Lias or not very long afterwards. The series thus represents a hitherto unrecognized phase of Karroo or early post-Karroo igneous activity. The felspathic materials of the vents include a unique rock-type containing 70–78·8 per cent of orthoclase, but with a potash content of 13 per cent—an amount which is even higher than is normally found in orthoclase itself. The gneisses and other rocks surrounding the vents are all altered, and sometimes they are thoroughly impregnated by the felspathic intrusive, with production of types comparable with Brogger's fenite-tveitåsite series (Fen Complex, Oslo District). The limestones of the Basement Complex in southern Nyasaland and the overlying younger limestones are of negligible bulk compared with the carbonate-rock of the vents and are also of different composition. The sedimentary or metamorphic limestones are accordingly rejected as a source of the carbonate-rock of the vents, which is regarded as of very deep-seated or even of magmatic origin. An account of Dr. Dixey's field work and that of C. B. Bisset, accompanied by the results of a petrographical investigation by W. Campbell Smith, will be published as a Bulletin of the Geological Survey of Nyasaland.

Temperature Measurements in Oil Wells

UNTIL recent years, systematic measurement of well temperatures has been impracticable owing to lack of a suitable instrument and technique. M. Schlumberger, H. G. Doll and A. A Perebinossoff, in a paper presented for discussion at a meeting of the Institution of Petroleum Technologists on November 10, describe how these difficulties have been to a large extent overcome by the evolution of an extremely sensitive recording thermometer and technique for its operation. The instrument is capable of being run through all normal sizes of drill-pipe and tubing, has an accuracy of 0·1° C. and permits continuous logs to be traced at 15 cm. per sec. without noticeable time-lag. When run inside the well, it is in contact with the fluid contained therein and consequently measures the temperature of the fluid and not of the surrounding formations. It can be used in wells in thermal equilibrium with their surroundings and also in wells in thermal evolution with equally valuable results; also in both open and cased holes. Moreover, in a well where the exchange of surroundings is not limited to heat alone, it is capable of recording actual material flows of oil, gas or water into the well. The advantages of the instrument are, therefore, obvious, but factors such as bottom-hole effect in drilling wells, size of the hole, nature of the fluid in the hole, etc., complicate interpretation of temperature diagrams. Close co-operation between a surveyor having experience of temperature measurement and a field staff familiar with local conditions is the prime necessity for accurate interpretation of temperature records, and only in this way can the maximum aid be drawn from them.

Production of Artificial Radioactivity by Deuterons

J. J. LIVINGOOD and J. J. Livingood and G. Seaborg have recently described the results of bombarding a number of heavier elements with 5-million volt deuterons from the Lawrence cyclotron accelerator (*Phys. Rev.*, 50, 425; 1936). Zinc, antimony, ruthenium, bismuth, tin were bombarded with deuterons (currents up to 3·5 microamp.) and in every case β-radioactivity was produced. The complicated decay curves show that several radio-elements are formed in each case, and tentative nuclear reactions are suggested. In some cases the new active elements can be identified by comparison of their decay periods with those of the products of bombarding neighbouring elements with neutrons. In the case of tin, a chemical separation of indium, tin, antimony was made, and each of these was found to be associated with a characteristic activity. The case of bismuth is particularly interesting. since the product of the reaction

$$^{209}_{83}\mathrm{Bi} + {}^{2}_{1}\mathrm{H} \rightarrow {}^{210}_{83}\mathrm{Bi} + {}^{1}_{1}\mathrm{H}$$

appears to be identical with the radium E of the natural radium series. It has the expected decay period, and it was possible to detect the α-particle activity of the polonium (radium F) formed by a successive transformation. The α-particles had the correct range. This is the first case of the synthesis of a naturally occurring radio-element.

Protium – Deuterium Ratio in Water

SEVERAL attempts have been made to determine the ratio protium – deuterium (^{1}H:^{2}H) in ordinary water, and the results mostly fall into two groups, either near 5500 or near 9000. The ratio has again been determined by a method which involves no extrapolation and in which the final value is approached from both the light and heavy side (N. F. Hall and T. O. Jones, *J. Amer. Chem. Soc.*, 58, 1915; 1936). The authors believe that many of the discrepancies found rest upon inadequate correction for alteration in the oxygen isotope ratio (^{16}O:^{18}O) in the water used. They paid special attention to this. Surface water from a lake was freed from deuterium by repeated electrolysis with recombination of the electrolytic gases. When the *deficiency* in ^{18}O thus caused had been restored by carbon dioxide equilibrium against the original water, the density loss due to deuterium alone was 16·5 γ. The same water was electrolysed in stages and the electrolytic hydrogen burned in air. The *excess* of ^{18}O thus introduced was removed in the same way, and the density loss was again 16·5 γ. Control of oxygen isotope ratio was exercised by index of refraction measurements. With the value 1·1074 for the density at 25° of pure deuterium oxide (oxygen normalized) the protium – deuterium ratio in Lake Mendota (Madison, Wis.) surface water is calculated to be 6,400 ± 200, taking account of the non-additivity of volumes. This is in good agreement with G. N. Lewis's early estimate of 6,500. Using the ratio 6,400, Aston's recent determination of the physical atomic weights of the hydrogens, and the Mecke-Childs' conversion factor, the physical atomic weight of ordinary hydrogen becomes 1·0083 and the chemical value 1·0081.

Range of Loudspeakers

LOUDSPEAKERS are of value not only for domestic use with radio sets but also for other purposes. The paper on "The Appraisement of Loudspeakers" by F. H. Brittain, of the Research Laboratories of the General Electric Co., Ltd., the first half of which appeared in the *G.E.C. Journal* of November, is of both scientific and commercial value. Mr. Brittain begins by enumerating the common imperfections of electro-acoustic systems and then considers in detail the effect they have on the performance of loudspeakers used in connexion with domestic entertainment, with public entertainment such as talking films, etc., and with public address systems. If the sound originates in a studio, the sound waves of frequencies lying between 50 and 7,000 cycles are usually clearly transmitted. If the sound originates under less carefully controlled conditions, such as 'outside broadcasts', the frequency band may be much curtailed. In the case of reproduction from a gramophone record, the frequencies recorded lie between 200 and 6,000 cycles, after which there is a progressive reduction in output until about 40 cycles, when there is a complete cut-off. The frequency discrimination of radio receiving apparatus is nearly always well marked. When using broadcast receivers, owing to the closeness of adjacent stations, it is not usually possible to receive frequencies above about 7,000 cycles, and this is only attained under favourable conditions. At the low-frequency end the cost of the equipment at about 80 cycles makes it necessary to reduce the output. With the loudspeakers at present in use, the small size of the average table set makes reproduction of frequencies below 80 nearly impossible. Even with the latest sets fitted with special devices, the frequency band never exceeds about 10,000 cycles. Further causes of failure are described and the methods used for measuring them are indicated.

Changes in the Spectrum of the Star 25 Orionis

A STUDY of the spectrum of 25 Orionis by Helen Dodson (*Astrophys. J.*, 84, 180) forms a useful contribution to the literature of bright-line stars. She has measured 147 spectrograms, covering the period 1915–33, and has found periodic variations in velocity (from both absorption and emission lines), line width, line contours, and line intensity ratios (V/R) for the double hydrogen emission lines. The velocity changes from the hydrogen lines are nearly synchronous with changes in the V/R ratio, but the period is not constant—having decreased from 1817 to 1025 days. The amplitude of velocity changes from individual hydrogen lines increases for the later members of the Balmer series; but the phase is the same for each, although the V/R ratio shows marked differences of phase from line to line. The helium lines are exceptionally interesting owing to the fact that their changes (in velocity and contour), while definitely related to the central hydrogen line velocities, are conspicuously out of phase with the latter. This is the only difficulty in accepting McLaughlin's hypothesis of a rotating, pulsating, nebulous atmosphere, which would account satisfactorily for all the remaining features of this and other similar bright-line stars.

Some Chemical Aspects of Nutrition

THE thirty-fifth Bedson Lecture was delivered by Prof. J. C. Drummond on November 20 at Armstrong College, Newcastle-on-Tyne, on "Chemical Aspects of some Modern Nutritional Problems".

Prof. Drummond pointed out that animals are dependent on plants for certain compounds which they cannot synthesize themselves from potentially suitable material. Such compounds can be divided into two types: tissue-building stores, and what might be termed 'chemical lubricants', for example, vitamins and hormones.

Cystine is a good example of the former type. Animals cannot synthesize this important amino-acid even if provided with sulphur, in various forms, and closely related compounds not containing sulphur, for example, serine. However, they can use menthionine, and dithioldilactic acid, but not homocystine and cystineamine to replace a cystine deficiency. Persons suffering from cystinuria who are given menthionine excrete it as cystine only.

Vitamins A, B_1, C and D are examples of the second type. In dealing with the work leading to the synthesis of vitamin B_1, Prof. Drummond pointed out that alteration in the position of the methyl group in the pyrimidine ring leads to the formation of biologically inactive products.

Vitamin A has been shown to be a C_{20} compound closely related to the carotinoid pigments. Those carotinoids possessing a β-ionone ring and a suitable side chain act as precursors of the vitamin. β-carotene itself is probably quantitatively converted into it. It is remarkable that the molecule divides at the central double bond considering that polyene chains are usually susceptible to oxidative attack at various points. Certain birds can use xanthophylls as vitamin A precursors, whereas other animals cannot. This suggests that there may be more than one vitamin A.

Chemical studies of vitamin C (*l*-ascorbic acid) are fairly complete, and it is interesting to compare the antiscorbutic activities of various substituted ascorbic acids. *d*-Ascorbic acid is quite inactive, *d*-arabo-ascorbic acid possesses one twentieth the activity, while *l*-rhamno-ascorbic acid and dehydro-ascorbic acid are less active. The preparation of these synthetic products possessing activity raises the question of the possibility of the synthesis of compounds of greater antiscorbutic power than vitamin C.

Turning to vitamin D (calciferol), Prof. Drummond said that it is generally held that rupture of one ring of its sterol precursor takes place during irradiation with ultra-violet light. Vitamin D activity is not dependent on the presence of a double bond in the side chain. Recent work on the antirachitic substance produced by irradiation of 7.dehydrocholesterol and on the products formed when 7.dehydrostigmasterol and 22.dihydro.7.dehydrostigmasterol are similarly treated was reviewed. The relation between constitution and biological action is not yet clearly apparent. There are two views to account for the activity of the various compounds. Either it is necessary to provide substances capable of being broken down to simpler molecules, or compounds with the same carbon skeleton as vitamin D are required. The former gleans some support from the fact that compounds, very different in structure from those obtained from natural sources, are capable of producing œstrus. For example, *l*-keto-tetrahydro phenanthrene and certain dibenzanthrone diols have some activity. A more remarkable case is that reported by Prof. E. C. Dodds, who found that dihydroxydiphenyl is active.

The Part played by Skin-Friction in Aeronautics*

THIS paper, running to some forty-seven pages of closely printed matter, is a book in itself. It is illustrated by twenty-seven figures, and is in five parts; Part I deals with resistance due to skin-friction, on an empirical basis, the determinations of Froude and of the many workers who followed him being presented in the form of a logarithmic diagram, in which, as is usual, ordinates give values of the constant C_0 (as in the expression $R = C_0 \rho V^2 \times 2a$) and abscissæ give Reynolds' numbers from 10^2 to 10^{10}; these numbers, denoted by the symbol N_R, cover the whole range from that proper to laminar flow, to that which obtains for ocean-going liners. The author points out that it is not possible to reconcile the wide variations in known data and gives a graph as indicating the probable minimum under ordinary average conditions. After a general discussion, an example is taken in the *Graf Zeppelin*; the hull resistance is calculated on the basis suggested by Froude in the case of ships; the horse-power is deduced for a flight speed of 80 m.p.h. and is in approximate agreement with that declared. A second example is given.

Parts II and III give in an abridged form the author's cyclic or vortex theory (sometimes referred to as the Prandtl theory) of sustentation, describing the two methods of treatment adopted by him in 1907 and 1914 respectively, and proving their quantitative identity. The criterion is shown to be the 'peripteral area' which defines the quantity of air handled by an aerofoil or the wings of a machine in flight. According to both methods the peripteral area is shown to be equal to 0·78 of the square of the span; that is to say, the area of a circle having a diameter equal to the span. From this the aerodynamic resistance may be calculated making use of the Newtonian principle of the equality of *force* and *momentum per second*. Parts II and III, though not directly concerned with skin-friction, lead up to Part IV, in which it is shown that the theory of sustentation has to be used in order to institute a comparison between theory and experiment. In Part II certain propositions which were first enunciated in the author's "Aerodynamics" are given.

---

* Synopsis of a paper by Dr. F. W. Lanchester, F.R.S., read before the Royal Aeronautical Society on November 12.

Part IV, which contains the gist of the whole paper, is devoted to a comparison instituted between theory and recent data furnished by experiments conducted in the compressed air tunnel at the National Physical Laboratory (Aeronautical Research Committee: Reports and Memoranda, 1627). The essence of the matter is that prior to the installation of this tunnel, it was not possible to conduct wind channel experiments at high Reynolds' numbers such as apply in the case of full-scale machines, and it had long been known or at least suspected that there is a great difference between high and low Reynolds' numbers. The extent of the agreement (or disagreement) was a matter of conjecture. *It is demonstrated that complete reliance may be placed on the predictions of theory under conditions of high Reynolds' numbers.* The examples taken for the purpose of investigation are aerofoils R.A.F. 48, Clark *YH*, and Göttingen 387; the results are given tabulated and as plottings.

In Part V it is shown that in contrast to the agreement found over a range of high Reynolds' numbers (namely, about 2×10^6 and upwards) theory can no longer be considered reliable. For the full-scale glider or sail-plane where the Reynolds' number is in the region of $1 \cdot 7 \times 10^6$, agreement is still good, but when the same methods are applied to the investigation of model aerofoils and gliders the discrepancies are shown to be considerable. The reasons for this are discussed.

In the four appendixes the more important matters are: A relation is established between the gross weight of an aeroplane and the Reynolds' number; and three diagrams are given, by the aid of which the Reynolds' number may be ascertained prior to design, if the projected gross weight and the aspect ratio are given. In Appendix III reference is made to the region of instability or uncertainty in the relations of C_0 to the Reynolds' number, illustrated by plottings due to Mr. G. Baker (1915) and Prof. Melvile Jones (*Rep. and Mem.*, 1199). Appendix IV is devoted mainly to the aerodynamics of flying at high altitude.

A Magdalenian Site of Southern France: The Cave of Isturitz[*]

IN continuation of the exploration of the palæolithic cave of Isturitz (Basses Pyrénées) by Dr. R. de Saint-Périer, of which the Magdalenian levels in the Hall of St. Martin have already been described (*Arch. Inst. Pal. Hum. Mém.*, 7; 1930. See NATURE, 128, 988; 1931), the Magdalenian deposits of the adjoining Great Hall, or Hall of Isturitz, as it has been named, have now been excavated; and it has become possible to take a general view of the Magdalenian culture of the site as a whole.

The Magdalenian deposits overlie Solutrean and Aurignacian levels, which are now being examined, without the intervention of any sterile layers. It is evident that both the Solutrean and the Magdalenian tribes established themselves here without any independent stratigraphic formation taking place. Both halls were occupied at the time the earliest Magdalenian deposits were laid down; but it is apparent that the occupation of the Great Hall was both longer and more intense than that of the Hall of St. Martin. Hearths, however, in the Great Hall are less frequent. A further difference is that while engraved plaques are exceptional in the Great Hall, though there art blossoms into great richness, in the Hall of St. Martin such plaques are numerous.

Although the age of the Magdalenian is that of the older Magdalenian of the Pyrenees, it is not, even at the base levels, the oldest stage of that culture. As is shown by the character of the lance-heads and certain of the engravings, these lower levels belong to Magdalenian iii, corresponding to Marsoulas. Above this is the culture of Magdalenian iv; but only in the Great Hall are found the harpoons, of which the evolved character points to a later occupation.

The most important period of occupation is Magdalenian iv, of which the chief characteristics are: a cold climate fauna, in which the horse is predominant, but a few retarded forms such as *Rhinoceros tichorhinus*, *Ursus spelæus* and *Hyæna crocuta* survive; and a lithic industry which is small and of mediocre execution, the various forms being not clearly defined and many implements being made from irregular and bad flakes. Burins are dominant. The bone industry is abundant, especially in the Great Hall. Many used bones show little sign of preparation for their purpose. The bone objects include needles, lance-heads of diverse types, *bâtons*, etc. A large number of the artefacts have been treated under a single classification as 'perforated'. The prototypes of harpoons found in the Great Hall already show signs of evolution.

The art forms of this period are here fully represented. They occur indiscriminately from bottom to top of the deposits of the period without distinction as to the level in which they are found. As already mentioned, the art of the Great Hall is richly developed both in the naturalistic form and in the conventionalized decorative motives. The naturalistic art in both sculpture and engraving shows remarkable powers of accurate observation of animal forms; while the conventionalized designs are clearly based on an equally accurate observation of the natural forms from which they are derived. One remarkable piece of engraving on bone represents a scene between a man and woman, of which the pose and composition depict graphically an expression of intense desire on the part of the male. The head of the woman and the lower part of the man are missing. The artist appears to have intended to represent the woman as thickly covered with hair over a great part of her body.

The abundance of the examples of this art in the Great Hall must account for the fact that, although much of it is of the highest quality, as a whole it is uneven and the choice of material is sometimes bad. The inferior may represent trial and practice pieces.

---

[*] Archives de l'Institut de Paléontologie Humaine. Mém. 17. La Grotte d'Isturitz. 2: Le Magdalénien de La Grande Salle. Par Dr. René de Saint-Périer. Pp. 140+12 plates. (Paris: Masson et Cie., 1936.) 120 fr.

In the levels of Magdalenian v and vi the climate is still cold; but the horse is less abundant. For a time the reindeer is important and then gives way to the deer. Birds become abundant. There is no very marked change in the character of the stone industry; the bone artefacts show a characteristic 'fossil' in the form of a staghorn point with a forked base; barbed harpoons appear. Objects of art become scarcer; sculpture disappears, and the art form is reduced to simple graving. Both realist and decorative art weaken and are less varied.

In the material of this level, the Azilians made their hearth. The stone industry above the Magdalenian levels resumes the forms of the Aurignacian culture with characteristic delicacy and beauty of retouch. Circular scrapers determine the Azilian character of the culture, their evidence being confirmed by the harpoons, which become more and more evolved.

With the close of this period man's occupation of the cave, save for burial purposes, comes to an end.

The British Institute of Radiology

ANNUAL CONGRESS AND EXHIBITION

THE tenth Annual Congress and Exhibition of the British Institute of Radiology was held at the Central Hall, Westminster, on December 2–4, 1936. The arrangements differed to some extent from those of previous years, notably in the inclusion of a section of the exhibition devoted to physical research. Among the institutions represented in this section were St. Bartholomew's, the Royal Cancer and the Mount Vernon Hospitals, Radium Beam Therapy Research, and the National Physical Laboratory, while Dr. Russell Reynolds showed an X-ray cinematograph apparatus. The section showed clearly the close connexion between physical research, even modern atomic physics, and the medical applications of radiations of all types. The exhibit of radium beam therapy research was concerned with a study of induced radioactivity, the principal item being a Geiger counter connected to a cathode ray oscillograph, the screen of which is photographed on a 35 mm. ciné film operated by a mechanism so designed that the speed of motion of the film varies logarithmically with time. By the use of this device, the film moves quickly enough to record the rapid counts of a newly activated material but slows down as the activity decays, so that considerable economy in the cost of film results.

The Royal Cancer Hospital and the Mount Vernon Hospital had exhibits dealing with X-ray and radium dosage, their measurement and typical results. The apparatus used at the Royal Cancer Hospital to determine the gamma-ray output of radium in röntgens consists of accurately made air-wall ionization chambers connected to a Lindemann electrometer, while the Mount Vernon Hospital exhibit included a valve amplifier of the DuBridge type working in conjunction with air-wall chambers and used for exploring the fields round radium sources.

The St. Bartholomew's Hospital exhibit included a demonstration of a simple form of Geiger counter employing a neon lamp for measuring weak beams of gamma-rays and locating missing radium containers, and also a series of photographic films illustrating the paths of alpha- and beta-rays in celluloid and in photographic emulsions.

The National Physical Laboratory showed, *inter alia*, transparencies illustrating the apparatus used in the standardization of X-ray and gamma-ray dosemeters and in the testing of radium containers, sensitive dosemeters for the measurement of stray radiation, and various X-ray crystal photographs dealing with the structure of teeth, electro-plating, corrosion and fatigue in metals, etc. A further exhibit consisted of a model of a periscope for observing patients undergoing treatment with very penetrating radiations. The optical system comprises eight concave mirrors, but the system is so designed that, although the light beams fall on the mirrors at approximately 45° to their normals, there is negligible distortion and the image appears normal size and nearer to the observer than the object.

The X-ray cinematograph equipment shown employs an indirect method in which the image on a fluorescent screen is photographed on 35-mm. ciné film, which has an emulsion specially developed to have a high sensitivity to the light emitted by the screen. In order to reduce the strain on the apparatus and the X-ray tube, an ingenious switch is incorporated so that the tube is only excited during actual exposure. The ciné camera is of the conventional type, fitted with a special lens operating at *f*0·8.

The session of the Congress devoted to physical and technical papers consisted in a symposium on "The Measurement of Ionization Current". Dr. D. E. Lea described a valve amplifier for the measurement of ionization currents which shares with the Townsend compensation method the advantage that the collecting electrode of the necessary ionization chamber is always substantially at earth potential. The ionization current is passed into a condenser connected to the grid of an electrometer triode the output of which is connected to two further stages of valve amplification, with the result that, in normal settings, a change of voltage of one millivolt on the grid of the electrometer valve brings about a change of voltage of ten volts in the output of the amplifier. The variation in the output voltage is thus sufficiently great to permit the operation of suitable relays and counting mechanisms through the intermediary of a thyratron. For the measurement of weak beams of radiations the rate of variation of the output voltage can be found over part of the full scale of the output voltmeter. By suitable adjustments the sensitivity of the instrument can be varied over a wide range.

Dr. G. W. C. Kaye, Mr. W. E. T. Perry and Mr. D. E. A. Jones described a ballistic amplifier in which troubles due to slow drifts and zero unsteadiness are avoided by isolating the detecting galvanometer from the anode circuit of the valve by the use of a blocking condenser. The apparatus may be used in two ways. In the first, the grid of the valve is maintained at zero potential with respect to the filament by the operation of a suitable potentiometer, the balance being tested by short-circuiting the grid resistance. If the system is balanced, short-circuiting the resistance does not alter the grid potential and the (ballistic) galvanometer does not deflect. The second method depends on the fact that, with the system unbalanced, the magnitude of the ballistic throw is proportional to the ionization current and to the capacity of the blocking condenser.

Mr. T. B. Lane described a radiation integrator designed to measure the total quantity of radiation used in a given experiment. An ionization chamber is connected to the grid of an ordinary radio valve, in the output of which a thyratron is connected. The grid of the amplifying valve is given a considerable negative bias, which is reduced by the action of the ionization current until the valve operates the thyratron, which in turn operates a counting mechanism recording the number of units of charge liberated in the ionization chamber.

In closing the discussion, Prof. J. A. Crowther said he was inclined to doubt whether the various more or less elaborate amplifier and counting mechanisms in regular use to-day really do offer advantages over the older types of electrometer, which are inexpensive and reliable, and only have the disadvantage that their use requires some experimental skill.

The seventeenth Mackenzie Davidson Memorial Lecture was delivered by Dr. J. D. Cockcroft, on the subject of "High velocity positive ions. Their application to the transmutation of atomic nuclei and the production of artificial radioactivity". Dr. Cockcroft dealt with this subject in his usual lucid and fascinating manner, describing the early work on atomic transformations carried out with alpha-particles, the later work with canal rays, accelerated by potential differences of many hundreds of kilovolts, produced perhaps by the Van de Graaff static machine or the 'cyclotron' of Lawrence. Pointing out how, while earlier experiments only succeeded in transmuting light elements, a large number of heavy elements have now been transmuted, and in particular bismuth has been changed into radium E, having the same radioactive properties as the naturally occurring element. As an example of the biological significance of the effect, he mentioned the work of Hevesy, who, by injecting into plants and animals mixtures of ordinary phosphorus and radiophosphorus, has been able, by means of Geiger counters and otherwise, to detect the movements of the phosphorus in the plant or animal and explore with some accuracy the distribution of the element at any time.

Educational Topics and Events

Cambridge.—Miss H. G. Wanklyn (Girton College) has been appointed University lecturer in the Department of Geography and Dr. S. R. Nockolds (Trinity College) University demonstrator in mineralogy and petrology.

Oxford.—The electors to Dr. Lee's professorship of chemistry intend to proceed to the election of a successor to Prof. Frederick Soddy on January 16, 1937. It is the desire of the sub-faculty of chemistry that, if possible, a physical chemist be appointed. To this end some changes in the statute defining the duties of the new professor were proposed in Congregation on December 1 and after discussion carried. The main difficulty of the new proposal, brought out in the discussion, is that while the new professor is to be given the direction of both the Inorganic and the Physical Chemistry Departments, there is, in fact, at present no official University department of physical chemistry, the whole of the teaching, and much of the research, in this subject being done in college laboratories.

It is now settled that Lord Nuffield's benefaction of £2,000,000 to the medical school is to be paid in thirteen equal half-yearly instalments for the next six and a half years. Mr. W. M. Goodenough of the Radcliffe Hospital and Barclays Bank has been appointed chairman of the Trustees.

The twenty-fifth Annual Conference of Educational Associations will be held at University College, London, W.C.1, on January 4–11, under the presidency of the Right Hon. W. Ormsby-Gore, whose presidential address entitled "Some Educational Problems of our Colonial Empire" will be delivered on January 5 at 5 p.m. On January 7 at 5 p.m., a joint conference on "Problems of Education within the Empire" will be held, when the speakers will include Sir Firoz Khan Moon, the High Commissioner for India, formerly Minister for Education in the Punjab; Dr. S. F. N. Gie, South African Minister in Berlin, formerly Secretary for Education, Union of South Africa; Prof. G. V. Portus, professor of political science and history, University of Adelaide; Prof. C. A. Krug, professor of education, Mount Allison University, New Brunswick; Prof. F. Clarke, director, Institute of Education, University of London. Further information can be obtained from the Conference Secretary, 29 Gordon Square, London, W.C.1.

The Annual Conference of the Geographical Association will be held in the London School of Economics, Houghton Street, Aldwych, London, W.C.2, on January 5–7, under the presidency of Sir Josiah Stamp, whose address, "Geography and Economic Theory", will be delivered on January 7. A symposium on "Whither Population" will be held, when Prof. C. B. Fawcett, Dr. R. R. Kuczynski and Sir William Beveridge, among others, will speak. Among the lectures to be delivered will be one entitled "Problems of the North-East Coast", by G. H. J. Daysh, and one of the discussions announced is "Broadcast Geography Lessons" in which L. Brooks, Dr. H. Thomas, and others will speak. Further information can be obtained from the Secretary, Geographical Association, c/o Municipal High School of Commerce, Princess Street, Manchester, 1.

Science News a Century Ago

Lord John Russell and the University of London

The Times of December 13, 1836, contained a copy of the Charter of the University of London signed on November 28, together with the letter of Lord John Russell to the Earl of Burlington, dated December 1, and the Earl's reply dated December 9.

In his letter, Lord John Russell said: "I have the honour to transmit to your Lordship the charter of the University of London.

"His Majesty has been pleased to approve of the appointment of your Lordship as Chancellor, and of Mr. Lubbock as the first Vice-Chancellor of the University.

"I feel convinced that it is not necessary to recommend to your Lordship either a zealous attention to the interests of learning, or a constant regard to those principles of religious freedom, which have furnished motives for the Royal grant. . . .

"You may be assured that on my part also I shall esteem it an honour to co-operate in the advancement of an institution destined to confer the distinctions justly due to proficiency in literature, science or art, without imposing a test of religious opinions, or binding by the fetters of the 17th century the talent and merit of this present enlightened age."

Among the scientific men who composed the "one body politic and corporate" entrusted with the affairs of the University were Airy, Neil Arnott, Captain Beaufort, W. T. Brandl, Faraday, Prof. Henslow, Mark Roget, Sheepshanks, James Walker and many others eminent in medicine.

Opening of the London and Greenwich Railway

On December 14, 1836, the London and Greenwich Railway as far as Deptford was officially opened by the Lord Mayor of London amid great rejoicings. The construction of the long viaduct of brick arches had been regarded as a very great achievement. Engines had been at work on the line for some time, but on the day of the opening five trains travelled to and from London Bridge and Deptford. "Comparing the sensation which the traveller feels on this," said a writer in *The Times*, "as compared with other railroads, one may state, that owing, no doubt, to the fact that the whole road being over archways, there is a rumbling noise which is not heard on other roads. Much of this, however, is obviated by the construction of the carriages."

At a luncheon held at the Bridge-house Tavern in the afternoon, the Lord Mayor said: "The great object which the new railway would effect was that of economising time; the great characteristic of modern commercial life was the value set upon time." In their replies to the various toasts, the speakers referred to the gratifying prospects with which the railway commenced, the great benefits such undertakings conferred upon commerce and upon domestic trade and "the great accommodation which this individual channel of communication supplied to the City of London and the town of Greenwich".

The Optical Phenomena of Crystals

In a paper entitled "Further Observations on the Optical Phenomena of Crystals" read to the Royal Society on December 15, Henry Fox Talbot referred to the property of some crystals, similar to those possessed by the tourmaline, of analysing polarized light. If a drop of a solution of sulphate of chromium and potash in tartaric acid is placed on a plate of glass, evaporation soon yields filmy crystals which frequently have this property. The plumose crystals of boracic acid when crystallized from a solution of borax in phosphoric acid also possess this analytic power, and present very beautiful appearances when viewed with the polarizing microscope. Talbot said that he entertained the hope that it would be possible to obtain large and permanent crystals, which would possess the advantages of the tourmaline, without the inconvenience resulting from its dark colour.

Societies and Academies

Paris

Academy of Sciences, November 16 (*C.R.*, 203, 961–1036).

Emmanuel Leclainche: Notices on Sir Arnold Theiler and on Edoardo Perroncito.

Henri Douvillé: The shell of the lamellibranchs: its formation in *Ostrea edulis*.

Charles Goldziher: Logistic extension of the mortality formula of Makeham.

Bertrand Gambier: Surfaces of which the asymptotics of either system belong to linear complexes.

Paul Vincensini: Surfaces deformable with transformation of kinematically conjugated systems into conjugated systems.

Jean Dieudonné: Derivatives of rational fractions.

Pierre Humbert: The extension to prepotentials of Kelvin's theorem.

Sklenar: A new aviation motor.

Robert Esnault-Pelterie: Remarks on the preceding communication.

Jean Chazy: Advances of the node and perihelion of a planet under the action of a circular ring.

Bernard Kwal: Quantic mechanics and the principle of relativity.

Pierre Vernotte: The theoretical dimensions of the cellular vortices of Bénard.

Gaston Dupouy: The utilization of the ballistic galvanometer as a null instrument.

André Lallemand: The application to photography of a method allowing the energy of the photons to be amplified. The application of an electric field to accelerate the photo-electrons.

Ernest Esclangon: Remarks on the preceding note. The method is important astronomically, especially in the fields of photometry and spectroscopy.

Jacques Rabinovitch: The magnetic rotatory polarization and magnetic double refraction of solutions of β-naphthol and of β-methylnaphthalene.

Léon Capdecomme: An arrangement allowing the vertical illuminators of microscopes to transmit rectilinear polarized light of any azimuth.

Maurice Curie: Phosphorescent glass. The influence of crystallization. Two specimens of zinc borate containing a trace of manganese oxide were prepared, one almost wholly crystalline, the other vitreous. The crystalline specimen showed strong and durable phosphorescence, the vitreous specimen almost none.

Henri Guérin: The melting points and densities of the tribasic alkaline earth orthoarsenates.

Etienne Canals and Pierre Peyrot: The fluorescence of some pure substances. Nine highly purified hydrocarbons showed no trace of fluorescence. Of all the pure substances so far examined, only oxygen compounds are fluorescent.

Jean Bureau: The hydrated magnesium nitrites.

Pierre Sue: The constitution of the hydrated alkaline niobates.

André Michel: Study of the solid solutions of ferrous sulphide with sulphur, selenium and arsenic.

Hubert Forestier and Mlle. Myriam Graff: The reduction of boric anhydride by manganese. Manganese reduces boric anhydride at a temperature below 1,000° C. forming a ferromagnetic boride (MnB).

Roger Testut: The formation of chromium carbides. By heating chromium powder with excess of carbon, two definite carbides are obtained, Cr_3C_2

and Cr$_3$C$_2$. The excess of carbon can be removed by heating in oxygen at 900° C., since neither of these carbides is oxidized below 1,000° C.

Charles Emile Brazier: The comparison of pyrheliometers. Two pyrheliometers measure the same physical magnitude only if, other things being equal, their apertures are exactly the same.

Roger Ulrich: Correlation between the elongation of the fruit and the development of the seeds in the wallflower, *Cheiranthus Cheiri*. The length of the fruit is proportional to the number of seeds, and this is not due to any mechanical action of the young seeds, since there are frequently large intervals between the seeds. It would appear that the seeds in the course of development exercise a stimulating influence on the growth of the pericarp.

Jean Beauverie: Studies in experimental cytology: the chromoplasts of species of *Ranunculus*.

R. Brunet and A. Jullien: The comparative architecture of the heart in some gastropod molluscs.

Robert Weill: The existence of polypoid larvæ in the cycle of the Trachymedusa *Olindias phosphorica*.

Philippe Joyet-Lavergne: Attempt at the valuation of the power of oxidation catalysis in the living cell. The reagent utilized for the study of oxidation processes in the living cell must fulfil two conditions; it must penetrate the cell without causing injury, and the colour changes brought about by oxidation must be appreciable. Alkaline solutions of cobalt sulphate or chloride have been found to be suitable for this study.

Pierre Nicolle: Physiological variations of the reticulocytary proportion in the course of gestation, during lactation and after ablactation in the rabbit.

Alexandre Lipschütz: A typical and destructive growth of the uterine glands after experimental ovarian interventions.

Boris Ephrussi and Morris Henry Harnly: The presence in different insects of substances intervening in the pigmentation of the eyes of *Drosophila melanogaster*.

Domingo Mauricio Gomez: The physical characteristics of the vessels, circulatory yield and law of decrease as a function of time of the arterial pressure.

Paul Durand, Paul Giroud, Edouard Larrive and André Mestrallet: Virulence of the fluids in the *maladie des porchers*.

Amsterdam

Royal Academy (*Proc.*, 39, No. 8, Oct. 1936).

L. S. Ornstein: Scattering of neutrons in matter (2).

Kingship and Kinship

FROM him to whom much has been given, much shall be required. The moving words with which on the night of December 11 Prince Edward took leave of his people, his subjects no longer, closed a great career of public usefulness, upon which strong hope for the future had been founded. That valediction, however, stands for far more than that. It marks the end of an epoch in which the relationship of the British Crown to the people has been peculiarly intimate and personal. It is true that the events of that momentous period of stress, which opened on December 2, have left the monarchy unshaken ; it is even strengthened ; but it would be idle to claim that it is unchanged. With the proclamation of His Majesty King George VI on December 12, a new era begins.

In the history of kingship, as has been shown by recent research, the well-being and virility of the king is identified with the prosperity and fertility of land and people. It is not without significance, perhaps, that it is precisely among the descendants of those peoples who relied most on the qualities of their king or chief as leader, the conquering Nordic peoples, to use a convenient descriptive nomenclature, that kingship has been most enduring. Yet if the king is the fount of honour, the leader in war, and in peace the source of law and order, as well as the supreme overlord of land and people, it is not in the sense of absolute monarchy in which Louis XIV claimed *l'état, c'est moi*. Britain, fortunate in this as in other matters affecting the liberty of its people, early won affirmation of the principle, which had governed the early kingship—even as now it regulates the powers of the paramount chief in parts of tribal Africa—that the king holds power in virtue of a trusteeship for his people and must rule in concurrence with his and their councillors. It is this principle, with many vicissitudes and obscurations, which runs through the weft of British constitutional development and the growth of self-consciousness in the people. It attained the full measure of imperial democracy in the Statute of Westminster of 1931, and first found opportunity for full expression, bitter though it was, in the tragedy of December 1936.

Events which in other days might well have given rise to revolution have passed without disturbance. That it has been possible for a great and unanimous volume of public opinion to crystallize without delay over the vast distances of the Empire is due in no small measure to the resources which science has placed at the disposal of our rulers in cable and wireless, aided by the newspaper press. It marks a new phase in the growth of democracy. But also it imposes a special responsibility on the new monarch.

It has been pointed out again and again in recent years that the King-Emperor is now the only link which binds together the independent nations which form the British Commonwealth. The new monarch has been acclaimed as "the people's King". This title confers upon him a great trust, but it lays upon him also a heavy burden, as guardian of the honour and integrity of his people. By his personal character and his sense of responsibility he will win the loyal support of his subjects in helping him to bear it. Now that the British Commonwealth of Nations has shown that it is no loose aggregate, but a closely knit unity, if of diverse parts, each of those parts will look to its king as its special representative, for whose services as arbiter, and as the interpreter of the constituent elements one to another, it will be prepared to pay with ever-ready loyalty.

General Science for Secondary Schools

THE science masters of Great Britain have hitched their wagon to a star; but, as men of science, they have selected the star with deliberate judgement and have satisfied themselves that the couplings are trustworthy. The interim report* on the teaching of general science just published by a sub-committee of the Science Masters' Association (after adoption by the general committee) is indeed characterized by the union of admirable ideals with sound good sense, and must be regarded as among the most weighty and most interesting of recent pronouncements on educational policy. There has long been on foot a movement to change the elementary part of the school science curriculum from its traditional, intensive and formal habit to a broader and more human shape; to substitute, in fact, a scheme of 'general' science for the rudiments of one or two branches of academic science hitherto constituting the usual course followed by School Certificate candidates. The terms of reference of the sub-committee were as follow:

> "To consider the problems presented to teachers in Secondary Schools by the introduction of courses in General Science as a constituent of general education, and to make specific suggestions about: 1. The aims to be kept in view. 2. The basic principles of the subject, an appreciation of which should be inculcated. 3. The material to be included in such courses. 4. Methods of development and treatment of the material. 5. Time-table requirements at different stages."

The report (1) summarizes the growth of this movement from its inception in 1915–16 to the appointment of the present sub-committee in 1935; (2) considers the aims of science teaching; and (3) suggests and interprets a syllabus of general science, with a special note on the biological section.

It is natural to turn first to the committee's views upon the aims of science teaching, for the curriculum and treatment to be adopted must obviously depend upon the ultimate objective. The report observes that the numerous reasons urged to justify the inclusion of any subject in the school course can be roughly classified under the three headings of (*a*) utilitarian or vocational, (*b*) disciplinarian, and (*c*) cultural; and the committee proceeds at once to make the important point that the preparation of technical experts cannot be considered as one of the functions of a school. We should have liked to see even greater emphasis given to this fundamental principle, which applies not only to the School Certificate stage but also to the two years afterwards spent in specialist studies by many boys and girls at school. We believe—and are confident that the vast majority of schoolmasters agree—that it ought to be no part of the business of a public or secondary school to train pupils for such professional examinations as the First M.B. The proper place for professional or technical training is the university or technical institution; and though parents may find it economical, and the university or institution convenient, to thrust a steadily increasing portion of such training upon the schools, the effect upon secondary education, already sufficiently serious, is likely in the long run to be extremely detrimental. On the other hand, the pre-preparation of experts is one of the schoolmaster's legitimate tasks, and, as the committee wisely remarks, "this can best be achieved by broadening the syllabus; for it is at school that particular talents are discovered and their development fostered. Many a potential specialist, in the life sciences especially, has been lost to the world by the narrowness of the teaching at school". The committee is too timid—or too polite—to add what should nevertheless be said in the plainest and most uncompromising English: that if the teaching at school is narrow, the fault is chiefly due to the stranglehold of the external examination system maintained by examining bodies under university control.

Vocational preparation, then, is relegated by the committee to a subordinate position, and this action is justified not merely on general grounds, but also because a purely vocational curriculum "presupposes a static, unchanging society" and because "the occupations of the people exhibit such amazing diversity that it is impossible to cater specifically for more than a small fraction". Where such a fraction is in practice catered for, the school authorities would do well to ask themselves whether they are not subsidizing some of their pupils at the expense of others.

---

* The Teaching of General Science. Science Masters' Association Interim Report of the Sub-Committee appointed in 1935. Adopted by the General Committee in 1936. (London: John Murray, 1936.) 2*s.* 6*d.* net.

Upon the second claim advanced in favour of the teaching of science in schools; namely, that it develops "certain powers of clear and vigorous thinking, of coherent and logical deduction, of exact and accurate observation", the committee discreetly adopts an attitude of reserve, accepting —or at least not disputing—the experimental evidence "that the possibilities of transfer of training are much smaller than had formerly been supposed". It is, however, a little disconcerting to find that the committee next draws the quite unwarranted conclusion that school science syllabuses should not include "any matter whatever which is taught *only* for the sake of the training it gives". Dr. Arnold's remarks on such a capitulation would have been pleasurable hearing; but since it would probably be impossible to isolate any topic the value of which is purely disciplinary, the committee perhaps penned this sentence tongue in cheek. The committee is, on the contrary, wholly serious in its insistence upon the cultural aim of science teaching, urging that "the peculiar intellectual glory of the Western peoples has been the creation of a Natural Science which is far in advance of that of earlier times", and that no one "can now be considered truly cultured, no one can be considered as having felt the European spirit at its best, if he has never had his imagination stirred by that great adventure of ideas on which we are engaged: the scientific exploration of natural phenomena". These are noble sentiments finely expressed; they represent the true spirit in which science should be taught.

The committee feels that the cultural and subsidiary aims of science teaching may best be achieved by arranging courses in as liberal a manner as possible, and by designing them to cover a wide range; but it is not blind to the difficulties which general science has to encounter. The details of the practical problem have therefore been attacked with courage, with skill, and, we think, with a considerable degree of success. In constructing an 'ideal' syllabus the committee adopted three criteria: (1) the selected material should call forth activity on the part of the pupils, (2) every item in the syllabus should lead to the understanding of fundamental scientific principles, and (3) the syllabus should provide a field suited to the cultivation of those habits, interests and sentiments which are fundamental to science. For the systematic way in which these criteria were applied, and for the ingenious method employed to frame a scheme in which each criterion was fully respected, reference must be made to the report itself; but the syllabus as a whole is so constructed as to help the pupil toward an intelligent understanding of his immediate environment, his own body being the central figure in it.

A particularly welcome feature of the scheme is that the committee, all the members of which have had wide experience of science teaching, abandons the pursuit of "breaking down the barriers between the special sciences" (a phrase which the members admit to have puzzled them), and frankly observes that the division of science into three main branches is both convenient and logical. The syllabus is accordingly divided into three sections, dealing respectively with physics, biology and chemistry, but the lines of demarcation are not emphasized, and the root of each section lies in the common experience of average pupils. The time which the committee suggests as adequate for the course is 451 periods of 45 minutes plus 29 periods for revision, that is, a total of four periods a week for four school years. This allowance—which is accompanied on the syllabus-charts by suggestions as to the number of periods to be allotted to each individual topic—appears to be ample, and it is probable that sets of more intelligent pupils would be able to get through a good deal more than the printed course. If so, the additional material might suitably consist for the most part of chemistry, to which the committee has assigned only 95 of the 451 periods, as against 197 to physics and 159 to biology.

This reduction of the chemistry section of the syllabus is, we feel, the weakest part of the scheme, and the committee itself is apparently not here sure of its ground. No doubt the chemists of the Science Masters' Association will see to it that this one blemish in an excellent—and obviously workable—course of general science is removed before the interim report becomes the final report. In the meantime, Mr. J. A. Lauwerys (convener), Mr. C. L. Bryant (chairman) and all the members of the sub-committee must be congratulated upon having brought a most exacting task to a very satisfactory conclusion. They have shown that elementary science in our schools can be vastly improved, and, more than that, they have shown how the improvement may be effected. Since the main criticism of general science in the past has been that it is impracticable, the present report may become a landmark in the history of scientific education.

Metallurgical Text-Books

(1) An Introduction to Physical Metallurgy
By L. R. Van Wert. Pp. xi+272. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 18*s*.

(2) The Principles of Physical Metallurgy
By Prof. Gilbert E. Doan. Pp. ix+332. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 18*s*. net.

(3) Principles of Metallography
By Prof. Robert S. Williams and Prof. Victor O. Homerberg. (International Chemical Series.) Third edition. Pp. ix+313. (New York and London: McGraw-Hill Book Co., Inc., 1935.) 21*s*. net.

(4) An Introduction to the Metallurgy of Iron and Steel
By Prof. H. M. Boylston. Second edition. Pp. xxii+563. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1936.) 25*s*. net.

ALTHOUGH the science of metallurgy has been a subject of university rank in Great Britain for many years—actually since 1851, when the Royal School of Mines was founded—the development of metallurgical courses in the United States has been much more rapid, and has taken place along somewhat different lines. It has always been the policy in British universities to give major attention to the extraction, smelting and refining of iron and the non-ferrous metals, and recently a more or less justifiable barrage of criticism has been directed at university authorities for their comparative neglect of the physical and engineering aspects of metallurgy.

The major advances in metallurgy since the beginning of the century have been concerned with the treatment and alloying of metals subsequent to smelting, and with their fabrication and adaptation to use in the engineering industries, and clearly a rather different training is required for metallurgical students who will eventually be employed in the metal working and engineering industries than for those who will be concerned with smelting processes. Some steps have certainly been taken to correct this bias in British metallurgical training, but in the United States physical metallurgy has for long been given the attention it deserves. (At the Massachusetts Institute of Technology, for example, a four-year course in physical metallurgy is provided, although at the same time it is doubtful whether this course can adequately fulfil its purpose without at least some process metallurgy as a background.) The four books under review are representative of the text-books provided for American university students taking metallurgical courses.

(1) Dr. Van Wert has for some years past been responsible for lectures in physical metallurgy at Harvard University, where his students have consisted of a somewhat heterogeneous group of postgraduate mechanical engineers and metallurgists. In the course of his work he was brought to realize that there was no introductory text in physical metallurgy which was at once sufficiently specific and fundamental for those who were to continue in the subject, yet interesting and comprehensive enough for those seeking a general knowledge of metallurgy and whose active acquaintance with it would probably end with the course. The present volume was, therefore, prepared to fill the need.

Dealing first with the common properties of the metallic state and of pure metals, the author proceeds without delay to a discussion of equilibrium diagrams along the usual and orthodox lines (without, however, the tiresome intrusion of the sodium nitrate-water diagram). The major portion of the two chapters devoted to this subject are not unnaturally concerned with simple binary equilibria, but some fifteen pages are taken up with an introduction to the study of ternary systems. The succeeding chapter deals with the micro-constituents of alloys, recrystallization and grain growth. In the chapter on the properties of alloys, hardness curves of representative systems are juxtaposed with the respective constitutional diagrams to emphasize the dependence of properties upon composition and constitution—a useful method for bringing this relation home to engineering students.

The final chapter deals with mechanical and thermal treatment; quite a good outline is given of the mechanism of plastic deformation of single crystals and polycrystalline aggregates, and annealing is considered at some length.

The book is excellently printed and well illustrated with photomicrographs and diagrams.

(2) Three years ago Dr. Doan, who holds the position of associate professor of metallurgy in Lehigh University, collaborated with D. M. Liddell in writing "The Principles of Metallurgy", which covered both process and physical metallurgy. The demand for a separate text on physical metallurgy

has led to the appearance of the present volume. The subject has been approached from the point of view of classical physics, commencing with the states of aggregation of matter, and emphasis is laid throughout on the principles of the behaviour of metals rather than upon individual metals or processes. At the same time, the basic processes and problems involved in the working and use of metals are considered.

The book is divided into three parts, the first dealing with the physics of the metallic state and the deformation and annealing of metals. The second part is concerned with problems of constitution and structure in binary and ternary alloys, and is well illustrated with photomicrographs and constitutional diagrams. In Part 3, under the heading of "Metal Technology", the various working processes are discussed. It is naturally not possible to devote more than a few pages to individual processes, but a clear outline is given of metal-working operations and foundry practice. Throughout, principles are most clearly set out and the book should be of considerable value to students, and, for that matter, to metallurgists and engineers in the metal working and using industries.

(3) This volume, which comes from the Massachusetts Institute of Technology, is frankly intended to serve as an introduction to more advanced works, and to fill the needs of those students of general science and engineering who do not specialize in metallurgy but who will use it to a limited extent in their professional work. Greater emphasis is, therefore, laid upon the applications of metallography and the microstructure of commercial alloys than upon physico-metallurgical principles.

The first edition appeared in 1919, and the need for the present third edition testifies to the appreciation which the book has gained among those for whom it was designed. In rewriting and rearranging the text, the opportunity has been taken to include a considerable amount of new material on aluminium alloys, alloy and stainless steels, laboratory and X-ray methods, and corrosion.

An appendix gives a suggested outline for a laboratory course in metallography and a descriptive list of the more important books and periodicals dealing with physical metallurgy. A comprehensive set of tables gives etching reagents for all types of alloys.

(4) The dearth of reliable text-books on iron and steel manufacture is as serious from the point of view of the student and young technical worker as it is amazing when the great size and importance of the industry in Great Britain are considered. Boylston's "Iron and Steel" was welcomed on its first appearance in 1928, and it is not surprising that a second edition has been found necessary. The author has endeavoured not only to reach students but also to interest the men who work in steel mills in obtaining a better understanding of their profession. In the present edition a number of modern developments have been described; several changes in blast furnace practice are mentioned, such as 'slow-blowing' and 'fanning' of the furnace, and the Brackelsberg melting furnace for foundry work is described in some detail. The Byers-Aston process for producing wrought iron on a large scale is described, and due attention is given to modern electric furnaces. No mention is made of recent practice in strip-sheet rolling, but otherwise the mechanical treatment of iron and steel is well covered.

Mycological Researches

Researches on Fungi
By Prof. A. H. Reginald Buller. Vol. 6: The Biology and Taxonomy of Pilobolus, the Production and Liberation of Spores in the Discomycetes, and Pseudorhizae and Gemmifers as Organs of certain Hymenomycetes. Pp. xii+513. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1934.) 28*s*. net.

IN this, the sixth volume of his researches, Prof. A. H. R. Buller, who has recently retired from the chair of botany at the University of Winnipeg, gives the full account of three lines of investigation on which he has been engaged for many years: (1) the biology and taxonomy of *Pilobolus*, (2) the production and liberation of spores in the Discomycetes, and (3) pseudorhizæ and gemmifers as organs of certain Hymenomycetes: preliminary papers on the first two have been published.

The account of *Pilobolus* occupies 224 pages, and is the fullest we have of the genus, though it must be added that a good deal of it summarizes and comments on previous work. The species of *Pilobolus* are usually coprophilous and are characterized by the shape, somewhat like an inverted Florence flask, and by the apical black-walled sporangium being forcibly shot off. The genus has been known and frequently described since the time of John Ray. The main point of the present account is the explanation of the method of sporangial discharge, which was rightly attributed to the subsporangial swelling acting as a squirting apparatus by Link in 1809. Buller in 1926 put forward the hypothesis that the swelling also acts as an ocellus. When the incident rays of light strike the swelling obliquely, this acts as a lens, and the protoplasm which receives the spot of light sends a phototropic stimulus down to the protoplasm at the top of the stipe just beneath the base of the swelling. The top of the stipe, elongating more rapidly on the one side, bends until the spot of light reaches the base of the swelling, which ensures that the free end of the *Pilobolus* 'gun' is directed towards the source of brightest light. The hypothesis is attractive, but it can refer only to half a dozen or so species. The lens action of the swelling has been investigated in various ways, and shadow photographs were taken. A large number of clear construction diagrams are given, but these disregard the deviation which must arise from the presence of the excreted water drops. Experiments on spore discharge gave six feet as the maximum vertical height for *Pilobolus longipes* and a little more than eight and a half feet as the maximum horizontal range.

The veteran mycologist, W. B. Grove, has contributed a taxonomic account of the Pilobolidæ (*Pilobolus* and *Pilaira*). This is a revision of his monograph of 1884, and gives clear and concise diagnoses of the species, but one would scarcely look for a monographic study in such a volume: whether or not, however, there is no justification for giving a taxonomic diagnosis of a new species in English and Latin in the general body of the work, and a repetition of the English one in the systematic account where it is headed "*Pilobolus umbonatus* Buller, in his Researches on Fungi. Vol VI, pp. 177–78, figs. 81–84, 87–91 (1934)" and ends "Illustration: Fig. 105. Other illustrations in this volume: Figs. 81, 82, 83, 84, 87, 88, 89, 90, and 91". There are similar unnecessary details in many places, including the legends to the drawings

The observations on spore discharge in Discomycetes deal first with the 'puffing' off of clouds of spores, a phenomenon often recorded by the old mycologists. The asci in many species are positively phototropic, and curve towards the mouth of the apothecium, and puffing produces a blast of air. A chapter is devoted to "The sound made by fungus guns and a simple method for rendering audible the puffing of Discomycetes". This summarizes some of Prof. Buller's previous work on the different genera, and records the hissing that is sometimes heard when one opens a box containing species of *Helvella* or other large species such as *Discina venosa.* The simple method mentioned in the heading is disappointing—"when the fungus is close to an ear, the puffing can be heard even when the room is not quiet and one is talking to one's friends".

The last part of the book contains interesting observations on a number of fungi. First, 'rooting bases' or pseudorhizæ in *Collybia radicata, C. fusipes*, *Mycena galericulata*, and *Coprinus macrorhizus* are considered. Usually, as in *C. radicata,* the pseudorhiza is annual and unbranched, but in *C. fusipes* it is branched and perennial. It arises as a small primordium on the surface of a buried root, etc.—becoming differentiated first into primordial pileus and stipe, the latter then differentiating into the primordium of the stipe-shaft and the stipe-base (pseudorhiza); this latter elongates by intercalary growth and pushes the rudimentary stipe-shaft to the surface of the soil.

The last chapter describes *Omphalia flavida*, the cause of the American coffee-leaf disease. The fungus was first known as *Stilbum flavidum* Cke., but a little more than twenty years ago Maublanc and Rangel, placing affected leaves of the Loquat in a moist atmosphere, found that the 'Stilbum' first developed and then the much larger sporophores of an agaric, which they named *Omphalia flavida.* Ashby later proved in culture that the two were really connected. Ashby's work has been confirmed by the author, who gives anatomical descriptions both of the basidiospore form and of the so-called 'Stilbum', which is really a gemmifer with a solid pedicel (not hollow as described by Puttemans), and a terminal, multicellular gemma shaped like a door-handle and detached by the wind. The mycelium is luminous both in culture and in leaf-spots—the latter fact having apparently been recorded in a letter to NATURE so early as 1880 (22, 292). The similar gemmifers of *Sclerotium coffeicola* are referred to.

The volume is produced in the same format as the previous ones, and written in the same style with an abundance of illustrations. From the contents of the present volume, it would seem that Prof. Buller has been rounding off some of the observations he has made in the course of his studies, and it may be that it will be some time before another volume appears. The first volume was published in 1909, and mycologists are under a deep obligation to Prof. Buller for his steady and continuous work which has brought many new and unsuspected facts to light. The highest praise is due to him for never losing sight of the fungus as a living organism. J. RAMSBOTTOM.

In Search of Beauty

Polly and Freddie
By Sir F. W. Keeble. Pp. iv+275. (London and Toronto: William Heinemann, Ltd., 1936.) 10*s*. 6*d*. net.

SIR FREDERICK KEEBLE was born in 1870. He was educated at Alleyn's School, Dulwich, and Caius College, Cambridge. His botanical researches earned for him the degree of Sc.D. (Cantab.) and the F.R.S. In succession he has been professor of botany in University College, Reading (now the University of Reading), editor of the *Gardeners' Chronicle*, director of the Royal Horticultural Society's Gardens at Wisley, controller of the Horticulture Food Production Department of the Board of Agriculture, an assistant secretary of the Board of Agriculture, Sherardian professor of botany at the University of Oxford, director of Nitram, Limited, and the adviser in agriculture to Imperial Chemical Industries, Limited. His contacts have been those of an accomplished scientific worker held in esteem by his fellows, a writer, a civil servant, an Oxford professor, a director of one of the units of the great industrial merger, Imperial Chemical Industries, the husband of one of the great tragedy actresses of our time and the neighbour of some of the most distinguished contemporary poets, archæologists and scientific workers.

The author's own and the varied interests of his friends and associates could have provided him with abundant material for a chronological survey of men and matters which his facile pen, wit and urbanity could have embellished into a work which would have given the greatest pleasure to his wide circle of acquaintances. But he has deliberately discarded the conventional technique of the biographer and written an autobiography which is a mixture of fantasy, allegory and fact, calculated to appeal to children as well as adults, to scientific workers who can take a delight in brilliant and charming exposition of the subject matter of science as well as to that wider circle of readers who do not resent the intrusion of an explanation of the facts of Nature into a book which has its full measure of human interest.

Throughout the book are staged the boy Freddie and next-door neighbour big-girl Polly, whom the author has endowed with the patience, sympathy, charm and inspiring qualities of a gallery of fair women. To this dream Polly he declares he owes his outlook on his work and his fellows, and to his early memories of Freddie he attributes his desire to quicken the interest of the children of to-day in the beauties of Nature. These he unfolds in delightful studies of growth, fertilization, budding, the green marine worm, the amœba, fascinating commentaries on evolution and mutation, and an illustration of the quality of the man Pasteur by a description of his experiments on anthrax. This appreciation of Pasteur is the finest thing in the book, a copy of which should be in every home.

A. G. C.

Early Chemistry and Geology

A Dictionary of Assyrian Chemistry and Geology
By Dr. R. Campbell Thompson. Pp. xlviii+266. (Oxford: Clarendon Press; London: Oxford University Press, 1936.) 21*s*. net.

THE classification of objects was a favourite pursuit of Assyrian scribes, as is shown by the long lists preserved in Ashurbanipal's library at Nineveh. Such texts were generally bilingual, that is, both the ancient Sumerian and the later Babylonian names are given, and sometimes explanations are appended. Stones, earths and metals naturally take their place in these lists, and in the accumulation of miscellaneous texts in cuneiform writing now published there is much scattered information about these materials.

Dr. Campbell Thompson's book is devoted to the collection of this information in an intelligible order, to the examination of the evidence provided by the names and by the uses to which the materials were put, and to the identification of the stones, earths and metals intended. That task must have been very arduous, as anybody who refers to the book will readily see; it demanded not only the work of a lifetime on the Assyrian language and writing, but also a special study of early geology, chemistry and manufacturing processes. There are, for example, important texts describing the making of glass, in the decipherment and interpretation of which Dr. Thompson has himself played the principal part. With the help of experts on glass, he has determined the character of the constituents named, often for the first time, and has an ingenious explanation of the weights of some of the minor constituents mentioned, which is much in excess of the amounts that could actually be used.

The interest of this work for the early history of science will be obvious to those who realize how little there is left, for example, about what the Greeks knew of stones and earths and their uses. Dr. Thompson is able to bring evidence to show that the practical science of the classical period was, in certain matters, derived from the ancient East, and even that in certain cases names known to the Assyrians continued in use and were known to Pliny. In fact the book puts the study of these ancient texts on a new basis. Stones and pastes used as prescriptions in the medicine of quite early times were not always included for magical reasons; the chemical properties were known and also their physical effects. Some earths and stones were used for making paints. The commercial employment of vitriol and gall-nuts was understood. All who are interested in the development of man's use of matter will find this apparently unreadable book absorbing and indispensable.

Pioneer work of this kind must, of course, be subjected to criticism and correction as the years pass, as Dr. Thompson would himself desire. The identifications are admittedly in many cases only probabilities or possibilities, founded, as is the case of *aqua regis*, on slender evidence. There are many arguments and statements which will appear doubtful. It is surprising to read that Mesopotamian unburnt brick is generally yellow, or to find that the salt excrescence on ground and brickwork can be thought to have borne a name meaning "smoke". Instances of this kind could be multiplied. But however much we may differ from individual statements and conclusions, the value of the book remains unimpaired. It is a storehouse of most interesting information on an abstruse subject.

The Call of the Orient

The Quest for Cathay

By Brig.-General Sir Percy Sykes. Pp. xii +280 +17 plates. (London: A. and C. Black, Ltd., 1936.) 15*s*. net.

SOMEONE once said that "The struggle between Europe and Asia is the binding thread of History; the trade between Europe and Asia is the foundation of commerce: the thought of Asia is the basis of all European religions". With this trenchant observation in our minds, we can read "The Quest for Cathay" with even greater attention than if it were a mere story of exploration, in the annals of which it creates a brilliant and vital chapter.

Except for the first pilgrim-explorers such as Hsuan-Tsang—"the greatest of early Asiatic travellers"—the quest centres principally around that period between the mid-thirteenth and mid-fourteenth centuries, an era of the greatest importance in world-history, for it was then that the West first discovered the East. Here is romance indeed, the principal figures being the Friars Carpini and Rubruquis, and the merchant-adventurers—the Polo family. Although Sir Percy Sykes traces the whole story from the earliest penetration of Asia by Alexander the Great down to the arrival of the Portuguese and the Jesuits in the Far East, no less than eight chapters out of eighteen are devoted to the exploits of these travellers, and rightly so, for they do indeed embrace the bulk of the knowledge that Europe gathered about the Orient at that date.

The direct results of the tales these pioneers brought back was that there arose a sudden and impulsive desire in the West for direct contact with the East. Venice and Genoa rose to fame and opulence, but it was not until the fifteenth century that the great quest was set in motion, and many serious attempts were made to reach India and Cathay by way of the North-West Passage, along the Arctic shores of Siberia and by the Caspian route. The great adventures of Dias, Covilhao, Columbus, Cabot, Vasco da Gama, Magellan, Jenkinson and Frobisher were all undertaken with the same object: all had the same prize in view—the untapped wealth of the Orient. Finally, Portugal discovered the sea-route to China, and the author considers the quest ended. But surely, if Jenkinson, ambassador to Bokhara and Persia, was in search of Cathay, those early ambassadors from Muscovy to the Manchu Court should be included in the roll of fame. Russia may have been a bit behindhand, but the story of her push towards the East could have added a chapter or two of surpassing interest, and could have introduced material, unlike that in the rest of the book, not easily come by.

The author adds a personal note to the oft-told tales of these early pioneers, having followed in the footsteps of many of them. The volume is well illustrated, and wisely includes nine copies of early maps.

Economists and the Public:

a Study of Competition and Opinion. By Prof. W. H. Hutt. Pp. 377. (London: Jonathan Cape, Ltd., 1936.) 15*s*. net.

PROF. HUTT has obviously enjoyed the preparation of this book. There are few writers on economics or its applications in social and political problems from Adam Smith, J. S. Mill, Herbert Spencer and Ricardo to J. M. Keynes, J. A. Hobson, W. Lippmann, H. Levy, H. J. Laski, Bertrand Russell and others of our own day at whose teachings he does not direct some shrewd blows. The charge of anonymous criticism which he condemns in Prof. Pigou's "Theory of Unemployment" can scarcely be brought against Prof. Hutt, who rarely fails to specify exactly the writer or teacher responsible for the views he criticizes.

It would be unfair, however, to represent this book as purely provocative or destructive in its criticism. Quite apart from the merits of its able presentation of a case for the competitive system based on much sounder arguments than those of the political platform or press, it is a most stimulating book to all who are concerned with social and economic questions, and particularly with the way in which scientific thought can penetrate society and be integrated into action and policy able to control the destructive forces which threaten it to-day. What Prof. Hutt has to say about the influence of custom on thought, the corruption of opinion, on plausibility and its dangers, on liberty, the basis of authority in opinion, and the independence of university teaching has implications which are very far from being limited to those primarily concerned with economics.

The book is never dull or superficial, and the ideal of economic liberty with equality of opportunity which Prof. Hutt's study of the competitive or *laisser-faire* system leads him to uphold has claims on the attention of all who retain their faith in reason. It can be recommended to all scientific workers who are facing the social consequences of their work, if only for the indications of basic principles to be applied in their thought on such questions and of the pitfalls to be avoided. R. B.

The Book of the Aeroplane

By Capt. J. Laurence Pritchard. Third edition. Pp. x+254+24 plates. (London, New York and Toronto: Longmans, Green and Co., Ltd., 1935.) 7*s*. 6*d*. net.

CAPT. PRITCHARD has succeeded in putting into this comparatively small book almost everything that the general reader wants to know about the aeroplane. He is to be congratulated also on the clear and interesting manner in which he explains such things as the distribution of pressure on the wing of an aeroplane, the functions of the various component parts, the controls, the problems involved in obtaining high altitude, high speed and long range, and the ground organization on flying routes. Chapter iii, "How an Aeroplane Flies", is, in particular, a model of clear exposition.

The author of a book of this kind, dealing with a science which is advancing with startling rapidity, suffers from the handicap that his work must always be a little out of date, even on the day of publication. This, the third edition (1935) of a work first published in 1926, takes us down to the date of Miss Jean Batten's flight from Port Darwin to Lympne, April 1935. That is the last entry in the list of famous flights which is a valuable feature of the book. The reviewer was a little disappointed to find no mention of the present very elaborate weather forecasting service for aviation, in the chapters dealing with "The Great Airways of the World" and "Safety in the Air"; but that was the only fault he had to find with this very interesting and useful book.

Collected Papers of Charles Sanders Peirce

Edited by Charles Hartshorne and Paul Weiss. Vol. 6: Scientific Metaphysics. Pp. x+462. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1935.) 21*s*. net.

THIS valuable addition to the collection of Peirce's writings illustrates the extreme variety and creative power of the great American philosopher. Among the notable contributions contained in this volume are the series of articles which first appeared in the *Monist* and were so much appreciated by William James. These articles refer to the doctrines of Peirce on chance (tychism), on continuity (synechism) and on love (agapism). Around these articles, the editors have collected and published a wealth of notes, additions and studies ranging from logistics to telepathy, and showing the diverse interests of their author. This new volume will greatly assist the reader in forming an adequate judgment on Peirce's thought and on the historical background of contemporary logic and methodology. T. G.

Il nucleo atomico

Per Franco Rasetti. (Trattato generale di fisica a Cura del Consiglio Nazionale delle Ricerche.) Pp. ii+232+3 plates. (Bologna: Nicola Zanichelli, 1936.) 50 lire.

IN this book, readers of Italian should find a very convenient, up-to-date and trustworthy summary of the more important aspects of radioactivity and their theoretical explanation in terms of wave mechanics. It is particularly well illustrated, and the subject matter is set forth in a direct and pleasing manner. It should form a handy guide for quick reference; but, on the other hand, it does not contain those long lists of references and footnotes which make the works of English writers in this field so valuable. L. F. B.

Bird Flight

Written and designed by Gordon C. Aymar. Pp. xii+234. (London: John Lane, The Bodley Head, Ltd., 1936.) 12*s*. 6*d*. net.

THE main feature of this American book is the series of some two hundred 'action' pictures of flying birds by various photographers, including the author. Many of them have appeared before, but they make a remarkable collection, containing much of interest and much of beauty. The text is undistinguished: it gives a brief popular account under the heads of evolution, biology, migration and aerodynamics.

Engineering and Empire Development

IN his capacity as the head of the oldest and most famous engineering institution in the world, the president of the Institution of Civil Engineers occupies a position of undisputed authority, the realization of the character of which has led successive presidents to deliver addresses which, taken collectively, constitute a history of engineering. Some of these addresses have been confined to the particular branch to which the speaker has devoted his life, others contain surveys of many branches, while others again contain valuable autobiographical or biographical sketches. Few of the addresses are not without permanent interest, and some thirty years ago *Engineering* referred to the whole as being to the Institution "a heirloom left it by the many great men who helped so devotedly to build up the position of our Empire".

The addresses of Telford and Walker, who occupied the president's chair from 1820 until 1845, were short and were mainly concerned with the activities of the Institution itself, and the prototypes of the modern presidential address are those of Sir John Rennie in 1846 and 1847, and of Joshua Field, in the two succeeding years. Rennie's first address runs to more than one hundred pages in the *Proceedings*. It dealt with a multiplicity of things including bridges, tunnels, harbours, gas, water, railways, steam carriages, steam navigation and telegraphy and even touched upon mineralogy, geology and meteorology. It reviewed the vast development of engineering from the time Smeaton began work on the Eddystone Lighthouse down to 1846, a period of ninety years. Twenty years later, Sir John Fowler spoke of this address as "a history of engineering and a manual of engineering science". A still longer address was that of Sir William White who, however, confined himself entirely to the progress of naval architecture and marine engineering during the preceding half century, a field in which he himself had played a part second to none. But whether the addresses have been long or short, whether they have dealt with wide surveys or a single subject, they are nearly all excellent reading, and over and over again reference has been made to the many great works designed and carried out by British engineers both at home and abroad, whether in foreign countries or in the British Dominions. There were, therefore, numerous precedents for Sir Alexander Gibb's choice of the title "Engineering and Empire Development", for his address delivered on November 3.

Sir Alexander himself, it is almost unnecessary to say, has had experience in many branches of engineering. Born in 1872, he was a student of University College, London, and then a pupil under Sir John Wolfe Barry and H. M. Brunel. Between 1905 and 1917 he was engaged on the construction of the New Alexandra Dock at Newport, Monmouthshire and the Royal Naval Dockyard at Rosyth, and during the Great War was chief engineer for port construction for the British Armies in France and Belgium. As senior member of Sir Alexander Gibb and Partners, he has recently been responsible, not only for the Kincardine Bridge but also for the great Galloway hydro-electric scheme in south-west Scotland. Unlike many of his predecessors at the Institution of Civil Engineers, his principal work has been done at home, but in choosing the subject of his address, he was inspired partly by the address of Rennie and partly by the opportunity he had had of inspecting the great engineering works in the Dominions and Colonies, which in the last ninety years have wrought a change in conditions overseas similar to those wrought at home in the ninety years covered by Rennie's address.

The world before Smeaton's time, Sir Alexander said, had apparently stood still; suddenly there arose a body of great engineers who, in a few years, created a new era. This, he suggested, was a natural evolution from the more abstract discoveries of science due to such as Copernicus, Galileo, Kepler and Newton. H. R. Palmer, actually the first member of the Institution, had said that "the Philosopher searches into nature and discovers her laws and promulgates the principles upon which she acts The Engineer receives those principles and adapts them to our circumstances". From the outset, engineers thus looked upon themselves as the practical exponents, for the ordinary use of mankind, of the scientific knowledge won by men of science and mathematicians. The basis and justification of the existence of the engineer, and his contribution to civilization, exist in the fact that the application of science to practical use is in fact engineering. The engineer of Rennie's time was of the type visualized by H. R. Palmer, and it is the same type of man who in the ninety years since 1846 has changed the face of the whole world and created the British Empire.

Dealing in turn with canals, roads, bridges, railways, ships, ports, transport, agriculture, irrigation, water-supply, sanitation, etc., Sir Alexander referred to such achievements as the canals which make it possible for ocean-going steamers to penetrate half-way across the continent of America, the 1,000,000 miles of roads which serve the Empire, the 12,064-ft. long Lower Zambezi Bridge, one of the longest bridges in the world, the railways of Canada, India and Australia, the trans-oceanic trade in foodstuffs and the developments of ports It is of interest to note that Smeaton's old chart of the Clyde showed a depth of 42 inches at high tide near a point where the *Queen Mary* was launched in 1934. Striking effects have been achieved by irrigation. It was after the famine of 1865–67 that irrigation was started in India on modern lines Famines do not now occur in India ; shortage and scarcity exist at times, but the possibility of areas of the size and population of Great Britain being left without food owing to the failure of a capricious monsoon has long since been ended.

Whatever has been accomplished, however, "the opportunites of the future," said Sir Alexander, "are vastly greater than any that the past has offered, but frankly, I look with anxiety on the years to come. The machine . . . sometimes seems to be taking control. Inventions and developments succeed one another with bewildering speed, and there seems, unfortunately, to be no limit to the possible results of uncontrolled and misapplied ingenuity. In such circumstances no one can say where Engineering may lead us or what limit there is to the power of the engineer. One thing is certain, and that is that there must be control".

Finally, Sir Alexander appealed for more co-operation between engineers themselves, for the subordination of personal and independent views and feelings to a common policy. "I would like it to be possible for one broad policy to inspire and guide all classes of engineer. I would hope that in time there would arise a body of engineering opinion so weighty, so authoritative, so sure, so sane, that it would prevent waste of energy and misplaced enterprise, and would inevitably command attention in the politics and administration and life of our country and Empire."

Soil Drift in South Australia

THE advances being made by deserts into areas occupied by man, sand drift, and desiccation, are problems which have awakened interest in several parts of the world. At the present time they are under consideration in the Middle West of the United States of America, in West Africa and in South Australia.

Under the auspices of the Council for Scientific and Industrial Research of the Commonwealth of Australia an important monograph (Pamphlet No 64, Melbourne, 1936) on this subject entitled "Soil Drift in the Arid Pastoral Areas of South Australia" by Mr. F. N. Ratcliffe embodies the researches carried out by the author into this important matter. The history of the investigations are given in a foreword. During the year 1935, the minister in charge of the Council (Senator, the Hon. A. J. McLachlan) asked that consideration should be given to the possibility of undertaking any action to combat drift of soil in the arid and semi-arid parts of Australia. Mr. Ratcliffe, an officer of the Council, was deputed to undertake investigations in typical areas such as the northern portions of South Australia. It is stated that the publication of the report must not be taken to mean that the opinions expressed in it necessarily represent the considered views of the Council.

The problem of soil drift in Australia, says the author, is not, of course, confined to the area dealt with in the report. In order to shorten the period given to the investigations undertaken, the work was confined to the pastoral areas of South Australia. In other regions vegetations differing in type from, and in many ways more complex than, those described in the report would have had to be studied. On the whole, it is considered very unlikely that the problem in, say, western New South Wales would differ essentially from that in South Australia, although the details of the picture might not be quite the same.

The problem of soil drift and the deterioration of the pastoral country is a factor of very considerable importance to Australia's future, as is the case in certain other parts of the world. It is therefore, as the author states, very desirable, if not essential, that its nature and the difficulties which it presents should be properly appreciated by laymen and administrators as well as by scientific workers. Since the laws upon which a country is governed are the work of the administration, the burden of responsibility for a failure to recognize and then deal with a state of affairs often aggravated if not produced by man himself rests with the administrators. Mr. Ratcliffe presents a very clear picture of the existing conditions and position in the past of southern Australia. It is of interest to note that some of the photographs illustrating the pamphlet have a marked resemblance to parts of West Africa on the south Saharan borderland. It is impossible here to follow the author throughout his investigations, but they may be summarized.

Mr. Ratcliffe holds the theory that the soil drift in Australia is chiefly, if not solely in parts, due to the excessive utilization of the soil by man, chiefly stock; that, in other words, the drift is the result of the disintegration of the soil layers *in situ* into loose particles which thus produce in the end a desert; that these desert conditions are not produced, or even assisted to any material extent, by sand or particles blown from neighbouring desert areas. He admits that this latter is the theory of the local farmers, who speak of the 'encroaching sand' or 'encroaching desert'. The author apparently holds strongly to his theory of the local origin *sur place* of the sand or drift resulting from the gradual deterioration of the soil.

It is difficult to follow this theory. May there not be a certain amount of sand invasion on to good stock grounds from areas outside which are in various stages of degradation down to pure desert conditions—as, in fact, is well demonstrated in the Sahara? Is there any great or sharp distinction between areas containing what Mr. Ratcliffe terms soil drift in Australia and the lands in the immediate vicinity of the Sahara on which the soil is still capable of producing a vegetation of use to man and his animals, but which gradually becomes overlaid with an ever-thickening carpet of blown sand? Is not this a possible factor in Australia? It is difficult to credit the fact that in these deteriorating lands in South Australia the conversion to drift and aridity is practically entirely produced *sur place*, through the admittedly improvident actions of the occupiers of the land by excessive stock grazing and so forth.

The author, after a study of the literature on the problem of erosion elsewhere in the world, considers that "conditions in the Australian arid pastoral areas have no exact parallel elsewhere, and thus the problem of their deterioration must be tackled on its own merits". It is difficult to follow the argument. The resulting aridity leading up to desert conditions in several parts of the world is an outcome of the excessive activity of man and his wasteful utilization of the lands in question, with the inevitable result that the water supplies commence to become intermittent, and then cease, the spring water-level or the water-table sinking in the soil to a depth beyond its possible further utilization for his purposes. The ensuing conditions and their origin in modern times would appear to have a considerable similarity in the three regions of the globe already mentioned.

The remedies suggested by the author, with suitable modifications easily ascertainable in the region in question, appear equally applicable and called for in all. "Permanent pastoral settlement," says the author, "is only possible when the stocking is in equilibrium with the vegetation, and not merely exploiting plant capital"; and he urges the need for readjusting the stocking policy of the arid pastoral country. This is an equally pressing problem in parts of northern Nigeria and in the French Colonies bordering on the southern Sahara.

Geomorphology of the Irish Sea Basin

By Prof. J. Kaye Charlesworth

A MORNING session of Section C (Geology) at the meeting of the British Association at Blackpool was devoted to a discussion of the geomorphology of the Irish Sea Basin. Although the discussion brought out perhaps little that was new, it outlined the main features of the evolutionary development which, treated historically, may have a wider appeal.

The Irish Sea-basin had its beginnings in the remote geological past. The sediments of the geosynclinal sea, which during Lower Palæozoic times obliquely crossed the site of the present basin with shore-lines far beyond the present coasts to the north-west and south-east, were compressed into concertina and less acute folds at the close and elevated into a mountain system At this remote date, the Irish Sea-basin appeared if only in shadowy outline, and there emerged the rim of mountains of hard rocks that, save in the Mournes then unborn, more or less surround the sea of to-day and exhibit in the trend of their valleys, ridges and geological strike lines, the north-east south-west Caledonian direction. The release of pressure probably initiated the tectonic

PHYSICS 92, Upper Circular Rd, Calcutta

subsidence of the Solway Firth and its continuation south of Co. Down that subsequent movements were later to accentuate, and gave rise to cross fractures, such as those which opened the southern part of the North Channel and the depression of the Dundonald valley and Strangford Lough.

The Carboniferous Limestone sea which transgressed the Old Red Sandstone desert that followed these events was in some respects the prototype of the present Irish Sea; its waters, as attested by shingle beaches, washed against the foot of the mountains of Down, Wicklow and Wales, the Lake District and the Isle of Man. The deltaic conditions that followed and led up to the Coal Measure swamps, with the aid of erosion, largely evened up the basin, so that at the end of the Coal Measure period probably but little of the elevations was left projecting. The succeeding American or Hercynian folding once again emphasized old tendencies and revivified the relief by doming the mountains along the old lines, as in Wales and Wicklow and the Lake District, where some of the Carboniferous Limestone doming must date from this time, and by dropping the rocks down along the periphery and re-opening posthumously the Caledonian fault-lines that ran north-west south-east.

The marine regressions and transgressions which, with their erosion and deposition, constitute the Mesozoic history of the basin doubtless re-fashioned this and partially effaced its earlier features. The close of the era indeed saw a plain emerge from the Cretaceous sea that was almost devoid of relief, though it was probably warped upwards over the sites of the ancient uplands and downwards over the Irish Sea and the Solway and Cheshire basins. The end of the Cretaceous is a datum-line of the utmost importance, for the present drainage, except in the region of the Tertiary igneous rocks of north-east Ireland, had its inception on the land-surface that then came into existence.

The Tertiary witnessed a further stage in the development of the basin as we know it. It saw the intrusion of the granites of the Mourne and Carlingford Mountains, which belatedly take their place in the enclosing rim. The foundering of the North Channel probably along its whole length and the opening of the Carlingford depression are of this date. Most important of all, however, the basin was the theatre of intermittent uplift. Periods of rest and planation are recorded in a number of peneplains which are beautifully developed throughout the basin. These periods were separated by others of downcutting and rejuvenation of rivers and of broad warping along the old lines when Wales and the Lake District, for example, were greatly domed and the Irish Sea floor between them and the Isle of Man was equally depressed. The planations still preserved to us include levels at about 1,800 ft., 600 ft., 400 ft. and 200 ft. above sea-level and, less certainly, at other heights. They seem to be later than the Tertiary igneous cycle of north-west Britain, for they cut across the igneous rocks in north-east Ireland and elsewhere intersect the dykes which extend from them. The last of the plains, of early Pliocene age, rises into the Central Plain of Ireland and extends through Co. Down and the coastal plains of Wicklow and Anglesey and underlies much of Cheshire and the Machars of Galloway. It was succeeded by still further uplift which enabled the rivers to cut gorges, now for the most part 'buried' or submerged. Towards the close of the Pliocene a reverse movement 'drowned' the lowest valleys and admitted the sea to a coastline which is still traceable in numerous places.

The Ice Age, the last chapter of this morphological history, did much to modify the topography which it inherited. Its glaciers sculptured the uplands, converted their V-shaped gorges into U-shaped valleys, hollowed out their floors into lakes, widened their heads into cwms and gave to the basin its only fiord, Carlingford Lough. The ice deposited its load as boulder-clay, drumlins, moraines and sands and gravels that mantle the plains and mask the Lias and Chalk which form much of the solid sea-bottom. It transformed the late Pliocene gorges into 'buried valleys', both within and without the present coast, concealed the preglacial shore-line along most of its length, and converted parts of the sea-floor into dry land, as in the Cheshire Plain, Vale of Clwyd, northern plain of the Isle of Man and the isthmus beneath Stranraer.

After the dissolution of the ice-sheets, the incoming temperate flora provided the forests which clothed so much of the surface when the sea was 100 ft. or more lower than now. A rise of the sea, due to general eustatic changes and to local movements of the crust, inundated these 'submerged forests' and isolated Ireland and the Isle of Man from Great Britain.

This age-long and never-ending evolution still continues. Running water is slowly paring down the land and dumping its detritus into the sea. The sea itself is wasting away the shores and silting up the bays and estuaries, and on-shore winds are piling up the dunes. The unstable ground is slowly tilting southwards, as is shown by the submergence of an occasional prehistoric site along the coast of Co. Cork and by the recent fine levellings of the Ordnance Survey in England.

Racial Theory and Genetic Ideas[*]

By Prof. H. J. Fleure, F.R.S.

THE newer concept of species makes it possible to consider both the origins of mankind and a classification of mankind in a new light freed from the limitation of requiring the sterility of crosses as a test of specific difference. The fact that human migrations from early times have had a scale, a range and a rapidity unknown among animals is another biological point of the first importance. We may give up both the view that mankind originated from a single pair or from a small group and the view that the different groups of mankind originated separately from prehuman ancestors. Rather should we picture groups of beings on the threshold of a full human status, with probably differences within the group as well as between groups, scattered over a wide area as more or less mobile collecting and hunting societies forming a sort of human network over a wide area of the Old World, stretching at least through North Africa and south-west Asia. The persons in different parts of the network would probably differ, but almost any part might contain individuals similar in many characters to individuals in other parts. With development of desertic conditions in North Africa and Arabia bringing increasing settlement near rivers, some degree of isolation and a high degree of long-continued local intermarriage developed, and no doubt different variations, at least some of them adaptive, occurred in different regions, so that:

(*a*) A number of small remnants of diverse early types remained, sometimes perhaps degenerate, as pigmies of the African and south-east Asiatic forests, as blackfellows in Australia and so on.

(*b*) African, Papuo-Melanesian, eastern Asiatic and north-western groups in the Old World became distinct, while drifts to America from eastern Asia added another chapter to the story. These may almost be called sub-species.

Characters, even those used in discussing so-called race types, are nearly always both genotypic and phenotypic. Stature is closely linked with environmental factors; nose-form may have some such link, perhaps an indirect one. A penetration of characters from the north into the Congo Forest shows that stature diminishes, more rapidly than nasal index increases, along the zone of penetration. It is most probable that hot, wet conditions and poor food have prevented higher stature from persisting, but it has apparently been more difficult to alter nose-form, so we get an aureole of fairly narrow-nosed people of short stature around the wedge of narrow-nosed taller people projecting into the forest.

Shaxby has shown that skin pigmentation changes gradually from the Sudan to near the Arctic Circle, where Scandinavia yields the Nordic type, as it is called. Similar points might be made in respect of other characters. Thus the pattern of the main mass of mankind in the Old World may be said to be one of transitions in some respects between certain 'standards' in Africa, Europe, Eastern Asia, Papuo-Melanesia.

A scheme based on transitions more or less under environmental influences is, however, not much more satisfactory than a purely geographical classification; for we cannot but be impressed by the fact that almost every population consists of disparate elements that reappear or persist side by side in a population generation after generation. We cannot treat an ordinary population as a unit to be described by giving means and standard deviations for each character. Those figures often are mere abstractions. We need to try to see how bundles of characters are grouped together, what bundles occur and seem to be transmitted as entities, and how the proportionate numbers with different bundles vary from district to district. For they do differ, and we can understand this better if we remember that each of us had, in theory, 32,768 ancestors about the time of the discovery of America, and 1,073,000,000 about the time of the Norman Conquest. As marriage was largely localized, and few rural areas with persistent intermarriage had a population of 32,000 in the fifteenth century, we realize how much branches of genealogical trees must intertwine, and so how possible it is for an element, a group of characters, that got into a locality long ago, through a good number of individuals, to go on century after century in spite of some intermixture with individuals from outside, provided it has not to work against a Mendelian dominant. Needless to say, the bundle of characters need not be, and is not, exhibited by every member of the local group, nor is any claim made that all members of the group are of strictly localized descent. We are dealing only with proportions of a population.

---

[*] Contribution to a joint discussion of Section D (Zoology) and Section H (Anthropology) on "Genetics and the Race Concept" at the Blackpool meeting of the British Association, on September 11.

Another necessary *caveat* is that the interpretation of differences between localities has to be done with great reserve unless we know from skeletons a fair amount about the back history of the district's population. Fortunately, as regards Egypt, we have the knowledge, from the work of Elliot Smith, Morant and others, that there has been a persistence of a bundle of physical characters from pre-dynastic days until ours. In Great Britain, in some areas once inhabited (*c.* 1900 B.C.) by the beaker-making people, the characters which distinguish their skulls are still found in certain cases among the modern population. In some areas of special isolation quite a number of people may carry and transmit a bundle of characters that seems associated with the very earliest population known from skeletal remains in Britain. The recurrence of these bundles is more than can be accounted for by any estimate of the probability of recombinations occurring in the course of intermixture; persistence seems the more likely hypothesis and the linkage of characters in a bundle is fairly obviously a feature.

We are, then, dealing with bundles of characters inherited more or less as such; diverse bundles often existing side by side. Even an interbreeding population, therefore, need by no means form a unit, and averages may mislead seriously. A pure race with essentially uniform bundles of characters in all its members probably does not exist; indeed, it is better not to use the term race at all in view of its painful misapplication in political discussions as well as of its inherent biological difficulties attached to the use of this word.

Obituary

Sir Edwin Deller

THE death of Sir Edwin Deller has robbed the University of London not only of a great administrative head, but also of a man beloved by all who knew him well. He died on November 30, from injuries received in an accident at the new buildings of the University in Bloomsbury.

Born at Paignton in 1883, the son of a carpenter, Edwin Deller left school at the age of twelve years to begin work as an office boy. Even in early boyhood he dreamed of a career in London, and as a youth he sought and found work there. After a period of other employment he entered the offices of the Kent Education Committee as a clerk, having chosen that position in preference to a better-paid post in a commercial house. He studied law in evening classes at King's College, University College and the London School of Economics, and graduated LL.B. with honours in 1911.

It was in 1912, at the age of twenty-nine years, that Deller first entered the service of the University of London, as secretary to the academic registrar. There he remained until his death, apart from war service in the Inns of Court O.T.C. and a short period in 1920 as assistant secretary to the Royal Society. He was invited to return to the University as academic registrar, and he held that office from the beginning of 1921 until his appointment as principal of the University in the autumn of 1929. In 1916 he gained the degree of LL.D. with a thesis on "The Liberty of the Subject".

Both as academic registrar and as principal, Deller served the University in times of exceptional importance. The period of his registrarship was one of great growth in the schools of the University, while his principalship covered the critical years, from 1929 onwards, in which new statutes came into operation and a new constitutional body, the Court, exercised centralized control over finance. Furthermore, his years as principal saw the arduous beginning of the vast building scheme in Bloomsbury. In both posts he was brilliantly successful; and it is difficult to believe that any other than he could have achieved an equal measure of success.

Endowed with vigorous health and blessed by a supremely happy home life with his wife and son, Deller brought to every task and to every occasion a wealth of energy, ability and human quality which made him an ideal administrator. He possessed in an extraordinary degree the power of radiating good humour and diffusing goodwill; of reconciling differences by discovering the measure of common purpose existing in apparently conflicting aims; and of going straight to the heart of a subject, often finding a clear solution where others had seen only an obscure problem. He delighted in working with scholars and men of science. Himself a man of wide culture, he shared their ideals and understood their ways. But he was equally at home with men of affairs, and indeed with all sorts and conditions of men. He gained to a most remarkable degree the affection, not only of members of his own staff, but also of countless colleagues in the university world at large.

Deller owed and acknowledged special allegiance and gratitude to three men with whom he was very closely associated in his work: to Sir E. Cooper Perry, principal officer of the University from 1920 until 1926, who was an outstanding influence in his life; to Lord Macmillan, chairman of the University Court; and to Mr. Harold Claughton, now clerk of the Court, and formerly secretary to the Senate. The delight of constant association with Deller in the work of the University was something which had to be experienced to be believed. One who experienced it for nearly three years recalls the daily talk with him (and one other colleague) about the work of yesterday and to-day, his irresistible sense of fun and extraordinary gift of sympathy, and his wise counsel and unfailing loyalty. It was easy to understand that in the Inns of Court O.T.C., where he had been a sergeant instructor, in the words of a comrade: "Recruits worshipped him, fellow N.C.O.'s loved him, officers valued and respected him".

In 1926 Deller visited the United States as the guest of the Laura Spelman Rockefeller Memorial. On his return he published under the title "Universities in the United States" some critical impressions which gained high praise in competent circles in America. He was deeply interested in American universities in relation to the community they serve; and the hospitality and friendship which he extended to visiting American scholars and administrators became proverbial. In 1927 he took a large part in the task of founding the British Institute in Paris; and up to the time of his death he served on the executive committee in London and on the educational committee, paying periodical visits to Paris and taking a keen interest in the progress of the Institute. He believed whole-heartedly in understanding and co-operation between France and Great Britain in general and between the universities of Paris and London in particular.

Many distinctions were conferred upon Sir Edwin Deller. One which he prized highly was his election as an honorary bencher of the Inner Temple in 1933. He was a fellow both of University College and of King's College. In 1932 he was made a Chevalier of the Legion of Honour "in recognition of his services in the cause of university relations between France and England". He was knighted in the New Year's Honours of 1935. T. F. S.

Prof. E. H. Kettle, F.R.S.

THE death of Prof. Kettle on December 1 is a serious loss to English pathology, coming as it has when he was at the height of his powers at the age of fifty-four years and when he had just got his department at the new British Postgraduate Medical School, London, well established and working productively. He was a London man, trained at St. Mary's Hospital, where he was afterwards on the teaching staff, going on to Cardiff in 1924, to St. Bartholomew's in 1927 and to his last post in 1934: he was elected into the Royal Society this year.

With Kettle goes one more of the disappearing race of general pathologists which the current specialization no longer produces, and he was an expert in bacteriology as well as morbid anatomy and ready to tackle any problem experimentally. Besides the ordinary contributions to knowledge which come from most laboratory workers, he will be remembered for suggestive work on the variation of the local inflammatory response to different bacteria and especially for his investigation, started originally with Dr. W. E. Gye, on the poisonous action of silica on the tissues and its relation to tuberculosis. This led him into the difficult field of industrial silicosis, which has in recent times turned out to be much more widespread and important than was at first supposed, and he showed clearly that it was the chemical character of the dusts rather than their mechanical irritation that determined the localization of tubercle bacilli which entered the body. Incidentally, he devised a very useful method of testing the potential danger of any industrial dust by animal experiment lasting a few weeks.

Hampered throughout life by a maimed leg and for the last ten years with recurrent and serious illness, Kettle never lost his buoyancy and his ready cheerfulness to teach his students and to guide young workers in the way they should go. He earned the respect of everyone and the affection of those who knew him well enough.

Rev. J. Gordon Hayes

THE Rev. James Gordon Hayes, Vicar of Storridge, near Malvern, died on November 21 in his sixtieth year. He devoted much attention to a critical study of the records of polar exploration and was the author of four outstanding books on the subject. In "Antarctica", published in 1928, he dealt with the natural features of the Antarctic continent and the journeys of explorers during the first quarter of the twentieth century. It was the result of a great amount of reading and gave an important comparison of the methods and results of modern explorers. This was followed in 1932 by a more distinctively historical work "The Conquest of the South Pole", designed as a continuation of Dr. H. R. Mill's "Siege of the South Pole" and showing deeper appreciation of the personal qualities of explorers than was apparent in the earlier work. The other two books, relating to north polar exploration, were "Robert Edwin Peary", an endeavour to show the improbability of that explorer having reached the pole, and "The Conquest of the North Pole", a well-balanced summary of Arctic exploration in the twentieth century.

Mr. Gordon Hayes, who had been a civil engineer before he entered the Church and had taken honours in history at Cambridge, was engaged on a work on Napoleon as a statesman at the time when the progress of his fatal illness put a stop to his labours. He was a tireless worker, an enthusiastic seeker after truth in all quarters, and a warm friend of all interested in polar exploration, by whom his cheery companionship will be much missed. H. R. M.

We regret to announce the following deaths:

Dr. J. K. Fotheringham, F.B.A., reader in ancient astronomy and chronology in the University of Oxford, on December 12, aged sixty-two years.

Sir Herbert Jackson, K.C.B., F.R.S., formerly director of the British Scientific Instrument Research Association, on December 10, aged seventy-three years.

Dr. A. A. Robb, F.R.S., author of works on aspects of relativity, on December 14, aged sixty-three years.

News and Views

John Maurice, Count of Bruhl (1736–1809)

THE bicentenary of the birth of John Maurice, Count of Brühl, recalls an interesting figure in the history of science in Great Britain in the eighteenth century. Born at Wiederau in Saxony on December 20, 1736, he studied at Leipzig, and at the age of nineteen years entered the Saxon diplomatic service and was sent to Paris. In 1759 he was transferred to Warsaw, and five years later, when but twenty-eight years of age, was appointed ambassador extraordinary to the Court of St. James. From the time of taking up his appointment in 1764, save for one journey abroad in 1785, he continued to live in England for the remainder of his life, and died at his house in Old Burlington Street, W.1, on June 9, 1809. He was devoted to astronomy, and effectively promoted its interests. Through his influence, von Zach, who was a tutor in his family in 1783, became an astronomer and assisted Bruhl in determining the latitude and longitude of Brussels, Frankfort, Dresden and Paris. He patronized the chronometer makers Mudge and Emery, wrote on time-keepers, was intimate with Herschel and delighted in transmitting abroad the discoveries made by him and others through the medium of Bode's "Jahrbuch". At his villa at Harefield about 1787, he built a small observatory, and a few years later equipped it with one of the first astronomical circles constructed by Ramsden.

Mr. A. B. MacDowall

A FREQUENT correspondent to NATURE about a generation ago was Mr. Alexander Baird MacDowall, who completed his ninety-third year on December 18. Mr. MacDowall was particularly interested in terrestrial and solar meteorology and the relationships between them, and most of his communications to these columns and to the Royal Meteorological Society dealt with this subject. The methods used by him, and some of the results, are typically illustrated in a small book published in 1895 with the title "Weather and Disease: a Curve History of their Variations". In this volume Mr. MacDowall showed, by means of graphs, the variations which certain elements of the weather and the mortality from certain diseases had undergone in the course of years. The mode of representation adopted by him was that commonly used at the time to illustrate the relation between two variables, the curves being subjected to a process of smoothing so as to record the averages of five or ten consecutive values.

IN a paper to the Royal Meteorological Society on April 21, 1897, Mr. MacDowall used this method of smoothed curves to make a comparison of weather statistics with the sunspot cycle, and was led to conclude that "In the climate of Western Europe there is apparently a tendency to greater heat in the summer half and to greater cold in the winter half near the phases of minimum sunspots than near the phases of maximum." Though the curve correspondences used by Mr. MacDowall and others to reveal periodicities have since been superseded by the periodogram and the statistical method of correlation, they were suggestive and represented a helpful stage in the understanding of meteorological relationships. Mr. MacDowall was a student at the Old College in High Street, Glasgow, under Prof. Thomson (afterwards Lord Kelvin), who influenced his whole subsequent career. After leaving Glasgow, he went to Berlin for a time and then voyaged to Australia and back in a sailing ship. He next settled in London and embarked upon a career of general journalism, working at the British Museum and the Patent Office. At that time he met Thomas Carlyle and became acquainted with D. E. Hughes, inventor of the microphone. In later years he has lived more or less in retirement and at present resides at Rothesay, Isle of Bute, where, in spite of his advanced age, he still retains active interest in scientific subjects.

Cultural Origins in Central America

NOTWITHSTANDING numerous attempts continued over a long period of years to trace the prehistoric civilization of Central America to its origins, the ancestral forms, especially of the culture of the Maya, remain obscure. It is now reported that a substantial advance towards a solution of this problem has been made by a joint archæological expedition to Yucatan of the Peabody Museum and the Smithsonian Institution of Washington, which has excavated a stratified site on the Ulua River, known locally as the "Beaches of the Dead". This site, the second only of the recorded stratified sites in this part of the world, lies on the fringe of the Mayan area. It has been known since 1929, when Mrs. Dorothy M. Popence was lowered by ropes into the channel which has been cut by the river through the deposits to collect skeletal material which had been washed out with potsherds and other debris from the culture-bearing strata. Dr. W. D. Strong, who is in charge of the expedition, now reports to the Smithsonian Institution the discovery at a depth of twenty feet of house-floors, refuse heaps and pottery fragments incised or painted in monochrome with designs which, though less elaborate, suggest an early Mayan type. Overlying this culture is a deposit of sterile clay, six and a half feet thick, and above this again is a deposit of burials and potsherds typically Mayan in character. The intervening cultural and chronological gap is partially filled by a culture from a site on the tributary Comayagua River, where an apparently transitional stage affords pottery of Mayan type that seems to shade into the "Beaches of the

Dead" style. On the evidence of its precedence in time and its similar but simpler character, it is suggested that the "Beaches of the Dead" type may be ancestral to the Maya style. Posthumous distortion has destroyed the evidential value of the skeletal material, beyond an indication of a general physical resemblance to the type of the Maya people.

Mosquito Control and Local Authorities

REFERENCE has been made in these columns on a number of occasions to the valuable work on mosquitoes and their control carried on by Mr. J. F. Marshall at the British Mosquito Control Institute, Hayling Island, Hampshire. The Institute was built and equipped by Mr. Marshall in 1925, and has become an important advisory and educational centre, which has been maintained almost entirely by him. Before he began his work, Hayling Island was infested with the salt-marsh mosquito and other species, but by dealing systematically with the breeding-places these pests have almost disappeared from the island. Experience has shown, however, that inspection and other control measures cannot be allowed to lapse if they are to be of practical value. This is evidently realized by the Havant and Waterloo District Council, which, in a Bill being presented to Parliament, includes a clause giving powers to the Council to "subscribe or contribute such sums as they may think fit to the British Mosquito Control Institute so long as that Institute shall remain established at Hayling Island and the Council shall consider its work contributory to the freeing of the district from mosquitoes".

HITHERTO, consent of the owners of property has had to be obtained to examine an area suspected to contain breeding places of mosquitoes or to deal with it suitably. The Bill mentioned above empowers the local council to take whatever action it may consider necessary for health's sake to inspect such areas or carry out measures of mosquito control. The clause relating to these powers reads as follows : "The Council may take all reasonable measures to make and keep the district free from mosquitos and with this object they may in particular (apart from any other measures)—(*a*) enter by their officers upon any premises which they have reasonable grounds for suspecting to be a breeding place for mosquitos and apply thereon any tests or examination for the purpose of discovering whether and to what extent mosquitos or their larvæ are there ; (*b*) require the owner of any premises upon which there is stagnant water or marshy ground which is a haunt or breeding place for mosquitos or contains the larvæ of mosquitos to drain the site of such water or such marshy ground to the reasonable satisfaction of the Council and to apply thereto such other treatment (if any) as the Council may reasonably prescribe." The inclusion of this clause in the Bill shows that the Council not only realizes the existence of mosquito pests but also the practicability of dealing with them by measures which have been successfully adopted during the past eleven years or so by Mr. Marshall as director of the British Mosquito Control Institute.

Exhibition of Electric Illumination

THE Science Museum is holding a Special Exhibition of Electric Illumination, which will remain open until April 25, 1937. Push-button demonstrations illustrate the principles involved in illuminating engineering practice, such as various types of reflection and transmission of light, reflection factors, effects of contrast, etc. Two full-sized rooms are devoted to decorative lighting and standard lighting system definitions. The great advances made in tungsten filament lamps are illustrated by exhibits showing the control now exercised during manufacture. The electric discharge lamp is dealt with in detail. Apart from examples of discharge lamps and their application to street lighting, industrial lighting and floodlighting, there are exhibits illustrating the cyclical form of the discharge and stroboscopic applications. All types from low-pressure tubes to water-cooled quartz tubes operating at 8,000° C. are shown. The phenomenon of luminescence, discovered by Crookes in 1879 and now applied to discharge lamps, is shown in considerable detail. By way of contrast, a concise historical exhibit illustrates the state of illumination technique through the ages. The exhibition has been arranged by Mr. W. T. O'Dea, of the Science Museum, with the assistance of the E.L.M.A. Lighting Service Bureau and an advisory committee under the chairmanship of Mr. C. Rodgers.

THE opening ceremony was performed on December 15 by Lord Rutherford, with Sir Henry Lyons, the chairman of the Science Museum Advisory Council and a past director of the Museum, in the chair. Lord Rutherford remarked that the subject is one which has interested him all his life. During the past ten years, there have been remarkable advances in illumination which, emanating as they have from pure science research undertaken in industrial laboratories, illustrate admirably the close relationship between science and industry. 80 candle-hours ten years ago cost the same as 300 candle-hours to-day, and this improvement happily comes at a time when it is really wanted in the cause of road safety. Some 25,000 hot cathode discharge lamps now illuminate 1,000 miles of road in Great Britain alone. With regard to modern developments in the application of the phenomenon of luminescence, Lord Rutherford said he hopes to live to see the time when we shall obtain light without filaments or electrodes simply by the conversion of invisible radiation. Mr. H. T. Young, president of the Institution of Electrical Engineers, in proposing a vote of thanks, mentioned the valuable educational work which can be done by such an exhibition ; it is expected that the exhibition will attract a quarter of a million visitors.

Modern Views on Infection and Disinfection

THIS was the subject of a Chadwick lecture delivered by Sir Weldon Dalrymple Champneys at Manson House, London, on December 9. Microbial diseases, he said, can be defined as a disturbance of health in man or other living things due to the presence of parasitic organisms, as a disturbance of the equilibrium between host and parasite unfavourable to the host. The reactions of any host to the presence of pathogenic organisms are numerous and complex, but are not mutually exclusive. Thus, the parasite may be rapidly killed by defensive mechanisms of the host's body, without giving rise to any symptoms of disease, or it may cause a local reaction known as inflammation. Fever is also a common result of infection, and tends to be a protective mechanism. Sir Weldon dwelt on the fact that a 'carrier state' may be established either following illness with apparent recovery without complete destruction of the invading parasite, or in consequence of a 'silent' infection without actual disease.

THE manner in which infecting parasites gain access to the body was then dealt with, the two commonest portals of entry being the skin and the nose and mouth. Infection may enter through the nose or mouth by the inhalation of infected droplets in the breath of patients or carriers, as with measles, influenza and others, or by swallowing infected food or drink, as in cholera and typhoid fever. The importance of the carrier state as a cause of cases or epidemics of infectious diseases was emphasized, and reference was made to the fact that different diseases may be caused by the same organism. For example, scarlet fever, tonsillitis, puerperal fever and probably acute rheumatism are all caused by various hæmolytic streptococci. In conclusion, Sir Weldon discussed measures of disinfection and prevention, and in regard to 'current' and 'terminal' disinfection, pointed out that treatment of infective material in the sick room during the patient's presence there ('current disinfection') is all that is necessary with most diseases. 'Terminal disinfection' after recovery or removal of the patient, upon which until recent years most reliance has been placed, is needless, and may be confined to the free use of soap and water with thorough ventilation.

Discoveries in Antarctica

A DISPATCH from the British Graham Land Expedition under the leadership of Mr. J. Rymill published in *The Times* of December 12 announces an important change in the map of Graham Land. In December 1928 Sir Hubert Wilkins in his flight over Graham Land reported the existence of two straits, Casey Channel and Stefansson Strait, in about latitudes 69° 45′ S. and 71° S. respectively, across the area known as Graham Land which previously was thought to be united to the Antarctic Continent. Between the two straits he mapped roughly the Finley Archipelago. The British expedition, sledging along the west coast of Graham Land, to lat. 72° S., long. 67° W., or ninety miles south-west of where Sir H. Wilkins turned, found no trace of these two straits and believes that low glaciers must have been mistaken for ice-covered straits. Thus Graham Land south of Crane Channel in the Antarctic Circle is restored to its former continuity with the continent. A further discovery of importance is that Alexander I Land, discovered by Bellingshausen in 1821 and sighted by Charcot in 1909, is not a small island but a large land area at least two hundred and fifty miles from north to south and separated from Hearst Land by an ice-filled cleft-like strait fifteen miles wide and 200 miles long. The expedition charted the eastern coast line of this island. The strait appears to be a fault feature with the eruptive rocks of Graham Land on the east and fossiliferous sedimentary rocks on the west or island side.

Hooker's Work on Lapachol and Related Compounds

THE yellow crystalline pigment lapachol, found in Bethabarra wood (from West Africa) as well as in several South American timbers, provided the late Dr. S. C. Hooker, the eminent American sugar technologist, with an absorbing problem in chemical structure which lasted a lifetime and has given us an admirable model of chemical research, based upon highly skilled technique, close observation, patience and careful deduction. The publication during the present year of no fewer than eleven posthumous papers by Dr. Hooker in the *American Chemical Journal* after a silence of forty years must have come as a complete surprise to organic chemists. But the work to which Dr. Hooker was so devotedly attached was interrupted by his long period of activity in industry. On his retirement in 1915, he resumed the problems which had remained untouched since 1896, and he was reluctant to publish prematurely the numerous results which he was able to collect in the last twenty years of his life.

HOOKER was born in Kent of British parents, but after studying in London under Japp and at Munich under Bamberger, with whom he undertook the investigation of retene, he migrated to the United States. His published work contains an account of the properties and structure of lapachol and of many closely allied compounds. Many of his results were obtained by close observation of minute samples under a microscope. Lapachol is a β-amylene β-hydroxy α-naphthoquinone, which undergoes isomerism with mineral acids into lapachone, involving ring-closure with the hydroxy-group and sometimes also change to the orthoquinone structure. But further structural changes of an unusual type are readily induced and we cannot fail to admire the skill with which he solved the problems of change of structure from the *p*-quinone to the *o*-quinone type, of the exact location of the double bond in the amylene group and of the mechanism of the process of oxidation, whereby the quinone-ring is first broken with elimination of carbon dioxide and then re-formed from the side-chain, in such a way that the next lower homologue of the original compound is formed. A memorial volume containing an obituary notice from the *Journal of the Chemical Society*, together with reprints of twenty-two memoirs from the same journal and the *Journal of the American Chemical Society*, has been edited by Prof. L. F. Fieser of the Converse Memorial Laboratory, Harvard University, to whom application may be made for copies.

Saints and Martyrs

In a lecture of this title recently delivered at the London Hospital and published in the *Lancet* of November 7, Dr. Donald Hunter, physician to the Hospital, remarks that the world to-day is too busy applauding successful military commanders, popular orators and authors to recognize that all its material advance has been achieved by men of science. He quoted numerous instances of scientific and medical men who were distinguished by having met dangers and often death for the sake of their work. In the first place he showed how our knowledge of toxic gases owed much to the self-sacrifice of pioneer workers, as in the cases of Gehlen, a Munich chemist, and Dr. K. C. Shierbeck, of Copenhagen, whose deaths in 1815 and 1920 respectively were due to arseniuretted hydrogen. In like manner, nitrous oxide proved fatal to Dr. S. R. Wilson in 1927, and hydrofluoric acid to Louyet and Nickles in 1869. In addition to numerous deaths among doctors and nurses due to attending patients suffering from acute infectious diseases, many laboratory workers have lost their lives in the investigation of certain dangerous tropical diseases, especially yellow fever, following experimental mosquito bites, as in the case of Lazear in 1900 and Walter Myers in 1901, pneumonic plague (T. C. Parkinson, 1909), verrugas (D. A. Carrion) and kala azar (W. R. Pirie). Numerous injuries and deaths from X-rays after many years of suffering occurred in radiologists before efficient means of protection were discovered, while it is not yet practicable to protect completely those who handle radioactive substances.

Work of the Meteorological Office

The annual report of the director of the Meteorological Office for the year ending March 31, 1936 (H.M. Stationery Office, 1*s*. net), describes the work done by that Office in its eighty-first year. Military operations are now so dependent upon the help of organized meteorology that an atmosphere of suspicion, merely, between European nations causes repercussions that affect the development of meteorology. In the year under review the Royal Air Force expanded: the Meteorological Office did likewise. Early in October 1935, an Overseas Division was formed to deal with Empire air routes, including the projected trans-Atlantic routes and the Empire air mail scheme. In addition, new stations were opened during the year at Aden, Khartoum and Gibraltar. As additional trained staff could not at once be produced to meet the emergency, the staff at headquarters and some out-stations in Great Britain had to be drawn on for service abroad, in spite of the general increase of work at home, which was augmented by the decision to carry out the scheme of grading and pay recommended by the Committee on the Staffs of Government Scientific Establishments presided over by Sir Harold Carpenter. These activities were not, however, allowed to prevent proper attention being given to two important conferences, the Empire Conference of August 1935 held in London and the International Conference of the following month in Warsaw. The Empire Conference met for discussion of research; the subjects for discussion were set out in sixty-eight memoranda. The International Conference was a gathering of directors of meteorological services, which among other achievements arrived at a uniform system of construction of synoptic weather maps—a valuable aid to international co-operation. The year's changes included also the setting up of an Overseas Division and the introduction in the official library on January 1, 1936, of a revised classification of meteorological literature based on that employed by the International Institute for Documentation.

Overhead Line Insulators

In a paper read to the Students' Section of the Institution of Electrical Engineers on November 30, Mr. C. H. W. Clark discussed the design, manufacture and testing of overhead line insulators. It is generally considered that 500,000 volts is the most economical pressure at which to transmit large quantities of electrical energy over long distances. The best material for insulating these lines has been found to be porcelain, as its insulating qualities remain practically the same when exposed to all weather conditions. It has low tensile strength but considerable compressive strength, and so most types of insulator are designed to utilize the porcelain in compression. Electrical failure follows a puncture through the porcelain or by 'flash-over' round its surface, which produces an arc short-circuiting the line. As puncture destroys the insulator, it is more serious than flash-over. Insulators are designed with a puncture voltage of about twelve times and a flash-over voltage of about six times the working voltage. Failures occurring in practice are usually due to lightning or to deposits of soot or sea salt on the insulator surface. Lightning affects the design of the transmission line rather than that of the insulators. Often no permanent damage is done by lightning flash-over. The problem of deposits on the surface of the insulators is a serious one and has not yet been completely solved, although many suggestions have been made for improving the standard types. For use near the sea, anti-deposit insulators have long, recessed, protected surfaces. For industrial areas, types with open exposed surfaces which can be cleaned by wind and rain have proved the best. For testing purposes, a percentage of the finished insulators are selected at random and tested for flash-over voltage both dry and in rain (produced artificially by a watering pot), impulse flash-over voltage, mechanical strength and electrical puncture.

Activities of the Imperial Agricultural Bureaux

The seventh annual report (1935–36) of the Executive Council of the Imperial Agricultural Bureaux has now been published (London: H.M. Stationery Office, 5*s*.). In view of the British Commonwealth Scientific Conference held in London this September, the volume is somewhat fuller than usual. Particular interest will perhaps be found in the individual reports of the several institutes and bureaux, where abundant illustration is afforded of the value now attached to them by the number and diversity of the inquiries sent from all parts of the Empire, quite apart from their regular work of preparing and distributing abstract journals. Research workers in South Africa, Queensland, Sierra Leone, Cyprus, Mauritius, Victoria, India, northern England and the Gold Coast have asked for and obtained assistance from the Mycological Institute in the identification of fungi. At the Entomological Institute, insects from every country in the Empire have been received for identification. Other bureaux have assisted in obtaining material for plant breeding work, in supplying seeds, in arranging for the analysis of foodstuffs; whilst the laboratory attached to the Imperial Institute of Entomology collected and sent to Canada nearly three million parasites to aid in controlling the insect pests which were attacking the forests in Quebec and the Maritime Provinces. In fact, the report marks for the seventh year the success of an Imperial service, organized on a co-operative basis and directly controlled by representatives of all parts of the Commonwealth.

Rock Gardening

THE art of growing plants among rocks disposed artistically is, perhaps, the highest form of gardening. It calls forth skill of an exceptional order, and provides a medium for expression of the highest sense of art. The Royal Horticultural Society and the Alpine Garden Society are therefore to be congratulated upon their very successful joint organization of a conference on rock garden matters, and an exhibition of tasteful grouping of alpine plants. The deliberations of this Conference, which took place at the Greycoat Street Hall on May 5–7, 1936, have now been published in book form by the Royal Horticultural Society ("Rock Gardens and Rock Plants." London: from the Office of the Society, Vincent Square, S.W.1, pp. 171, 6*s*. net, 1936). Mr. F. J. Chittenden has edited this report of proceedings. Practical considerations were well to the fore. The utilization of natural slopes and of flat sites, the cultivation of difficult alpine plants, methods of propagation, the use of an alpine house, and other problems, were discussed. The history of rock gardens was outlined, and a very pleasing international atmosphere was introduced by the speakers who described rock gardening in South Africa (Miss Stanford), in Quebec (Mr. Cleveland Morgan) and in Southern California (Mr. W. Hertrich). The impression gained from the volume is that the artistic side of rock gardening could scarcely be improved, and that present-day practice is enlightened and highly skilled. There are abundant indications, however, in the papers and in the energetic and constructive discussion which followed them, that there is a field where a sympathetic man of science, working upon rock-garden problems, might furnish great contributions to practice, and satisfy many botanical questions which must at present be left unanswered.

Forestry in British Honduras

THE report of the Forest Trust of British Honduras to the end of December 1934 (Belsize: Govt. Printer, 1935) shows some progress in forestry work after the severe experiences following the 1931 financial crisis. From the Colonial Development Fund grants were made towards forest development in the Colony. The chief of these grants was to provide the staff to undertake a forest resources survey of the country, provided that the local Government contributed towards the cost and that the officer seconded for the work was replaced on the executive staff by an additional officer. The step so taken furnishes evidence of a broad vision on the part of the officials forming the Forest Trust. The term 'research work' accorded to what is mainly ordinary stock mapping of a forest—the work, or part of it, of the trained forest officer—is rather out of place, if not misleading. The staff of the Department, consisting of three gazetted officers, is still too small to make any considerable advance in executive forestry work a possibility. It is not therefore surprising to find in the Report such remarks as "No new reserves have been created"; "No new demarcation work was undertaken"; and, in spite of the magnificent start made in the early years of this young Department, that "No sylvicultural work has been done since the completion of the mahogany improvements in 1931". The end of the year 1934, which appears very distant at the present day, seemed to show an upward tendency in a timber trade revival. It was estimated by the Trust that the export of mahogany, that magnificent forest product of the British Honduras forests, would not exceed five or six million board feet per annum in the immediate future, and that a large proportion of that export would be in lumber form.

Exhibition of Microscopes

MESSRS. W. WATSON AND SONS, LTD., held their fourth exhibition of microscopes at the Central Hall, Westminster, on December 7–11, when the manifold uses of the microscope were practically illustrated, and many different types of instrument were on view. Members of the Quekett Microscopical Club were helpful in explaining points of interest to the scientific microscopist and instilling enthusiasm for microscopy in the amateur. A large number of different microscopes, from the comparatively simple student's microscope to the more intricate type used for research purposes, was on view. Other apparatus being demonstrated included photomicrographic and other cameras, dyes and stains, dissecting instruments, micro-projectors, telescopes, and other optical instruments. Messrs. Chance Bros. supplied an exhibition of glass in various stages from the rough mass to the finished optical lens. Messrs. Kodak also had an exhibition, as also had Polarisers, Ltd. A catalogue of the exhibition forms a useful guide to scientific workers in the many branches of science in which the microscope is indispensable and also to the amateur microscopist. The catalogue can be obtained from Messrs. W. Watson and Sons, Ltd., 313 High Holborn, London, W.C.1.

New Tests for Milk

The Minister of Health has issued a pamphlet giving directions for carrying out tests to ascertain whether milks entitled to be called 'tuberculin tested', 'accredited' or 'pasteurized' comply with the prescribed standards for the bacterial content of such milks. These standards indicate the cleanliness and keeping qualities of the milk (Bacteriological Tests for Graded Milk (Revised Memorandum 139/Foods. London: H.M. Stationery Office. 3*d*.). Since June 1, 'tuberculin tested' milk has taken the place of 'certified' and 'Grade A (Tuberculin Tested)' milks; and 'Accredited Milk' that of 'Grade A' milk. In place of the previous 'plate-count' test, a new test, the methylene blue reduction test, will be applicable to these milks from January 1, and as before, there is a test for the presence of coliform bacilli. Pasteurized milk, whether 'tuberculin tested' milk or not, must comply with a 'plate-count' test. Full directions are given for carrying out these tests, and the pamphlet also explains how samples should be collected.

Marine Boring Animals

The damage which may be done to submerged structures of both wood and stone by marine boring organisms is a subject of not only general interest but also of extreme economic importance. In 1919, therefore, the Trustees of the British Museum caused a general account of the habits and life-histories of these organisms to be prepared which, it was hoped, would prove useful to both zoologists and marine engineers. This hope has been amply fulfilled, and the Trustees have now issued a revised edition of the pamphlet incorporating the additions to our knowledge of marine borers which have been made since the publication first appeared (Marine Boring Animals injurious to Submerged Structures. By W. T. Calman. Second edition; revised by G. I. Crawford. British Museum (Natural History), 1936. 1*s*.).

Announcements

At the annual meeting of the Royal Agricultural Society of England held on December 9, the Right Hon. Walter Elliot, a former Minister of Agriculture and now Secretary of State for Scotland, was presented with a certificate and badge of honorary life governorship of the Society. In the report presented at the meeting it is stated that the Society's Gold Medal and honorary membership for distinguished services to agriculture has this year been presented to Sir William Cecil Dampier. For some years Sir William has devoted his energies to the organization and development of agricultural research. He was the first secretary of the Agricultural Research Council and steered that body to success through its early difficult years.

An important experiment in the prevention of malaria, according to the Soviet Union Year Book Press Service, was recently carried out by the Sanitary Department of the Central Asiatic Military District. Before the autumn manœuvres, every soldier was given a dose of acraquinine for several days, and although the manœuvres took place in malaria-infested districts and there were cases of bites by malaria-carrying mosquitoes, not a single case of malaria occurred.

The Royal Statistical Society offers the Frances Wood Memorial prize, value £30, for competition in 1937. The prize is offered for the best investigation, on statistical lines, of any problem affecting the economic or social conditions of the people. Further information can be obtained from the honorary secretaries of the Royal Statistical Society, 4 Portugal Street, W.C.2.

Erratum.—In the note on p. 1003 in Nature of December 12, Sir Robert Mond should have been described as president of the French Society of Chemical Industry and not as "past-president".

Applications are invited for the following appointments, on or before the dates mentioned:

Technical officer at the Royal Aircraft Establishment, South Farnborough, Hants—The Chief Superintendent (December 26).

Civilian engineer in the War Department—The Under-Secretary of State (C.5), The War Office, London, S.W.1 (December 31).

Principal of Newport Technical College—The Director of Education, Education Offices, Charles Street, Newport, Mon. (December 31).

Assistant in the Art and Ethnographical Department of the Royal Scottish Museum, Edinburgh—The Director (December 31).

Research assistant in botany in University College, Exeter—The Registrar (December 31).

Assistant physicist in the Royal Cancer Hospital (Free), Fulham Road, London, S.W.3 (January 1).

Lecturer in chemistry, botany and zoology in the Technical College, Doncaster—The Secretary (January 2).

Head of the Chemistry Department of the Derby Technical College—Clerk to the Governors, Technical College, Green Lane, Derby (January 9).

Lecturer in native administration in the University of Cape Town—The Secretary, Office of the High Commissioner for the Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (January 15).

Research worker in nutrition in the Medical Research Department of the Government of India—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2 (January 15).

Metallurgist for work on alloy steels and metallurgist for work on non-ferrous alloys in the Mond Nickel Co., Ltd.—The Manager, Research and Development Department, The Mond Nickel Company, Ltd., Thames House, Millbank, London, S.W.1.

Physical chemist to the Printing and Allied Trades Research Association—The Director of Research, 10 Robin Hood Court, London, E.C.4.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1060.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Liquid Crystalline Substances from Virus-infected Plants

STANLEY[1] has described the preparation of a crystalline protein possessing the properties of tobacco mosaic virus from the sap of infected tobacco and tomato plants. The crystals were small needles made by precipitation with acid ammonium sulphate. We have confirmed these results, but have found that by further purification the protein in neutral aqueous solution can be obtained in liquid crystalline states.

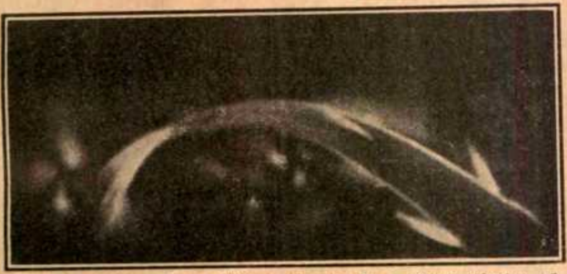

FIG. 1. Wake of a goldfish swimming in a dilute solution of protein from infected sap (observed between crossed nicols). *Photo by Ramsey and Muspratt.*

The sap of tobacco and tomato plants infected with strains of tobacco mosaic virus, after clarification by centrifuging, contains five to ten times as much protein as sap from similarly treated uninfected plants. This extra protein can be precipitated from dilute salt solutions at around pH 3·4 and from neutral solutions with from 10 to 12 per cent ammonium sulphate. The protein in uninfected sap is not precipitated under these conditions. Using these properties, 1–2 gm. of protein can be isolated from a litre of sap; the yield varying with the age of the infected plant and the duration of infection. No enzyme preparation has yet been found which can attack the protein at an appreciable rate, and some impurities can be conveniently removed by incubation with trypsin.

We have worked with three strains of tobacco mosaic virus, those causing common tobacco mosaic, aucuba mosaic and enation mosaic. No gross chemical or physical differences have been found between the three proteins isolated, but each reproduces its characteristic disease when inoculated to susceptible plants. Differences in detail, which will be described in a later publication, have been noticed. Solutions of the protein are antigenic, and the antisera produced in rabbits give specific precipitates with 1 c.c. of solution containing 10^{-7} gm. The three proteins are serologically related. Plants inoculated with 1 c.c. containing 10^{-9} gm. usually become infected, and occasional infections have followed inoculations of 10^{-11} gm.

These proteins, when precipitated with acid and dried, have the usual analytical figures: C 51 per cent, H 7·1 per cent, N 16·7 per cent. The sulphur contents vary from 0·2 to 0·7 per cent and there is 0·5 per cent phosphorus and 2·5 per cent carbohydrate. The last two constituents can be isolated as nucleic acid of the ribose type from protein denatured by heating. Neutral aqueous solutions of the proteins are almost colourless and faintly opalescent. The protein sediments in a centrifugal field of 23,000 times gravity at about 5 mm. per hour and is deposited as a very viscous layer containing up to 30 per cent of dry matter. Highly purified protein solutions, if stronger than 2 per cent, separate into two layers on standing. The lower layer, which may be water clear, is liquid crystalline. The birefringence depends on the concentration, but may rise to 0·002. The upper layer shows, on gentle agitation, the phenomenon of anisotropy of flow. This was noticed by Takahashi[2] in clarified sap. We have, however, been unable to confirm his later claim that the effect could be observed in healthy tobacco sap. The orientation will persist for several seconds in purified solutions, but if the solutions are impure or dilute the persistence is much shorter. This effect is illustrated in Fig. 1, where the wake of a goldfish swimming in a dilute solution is clearly shown; the cross of isocline will be noticed in the eddies.

Solutions can readily be orientated by electric currents, but not by magnetic fields of 6,000 gauss. The lower layer orientates itself by flow like the top layer and also tends to orientate parallel to glass or air surfaces. On flowing through small capillary tubes it can be thrown into a state of reversed spiral vibration[3]. When small portions of lower layer are in equilibrium with the top liquid, they appear as spindle-shaped bodies (see Fig. 2) which are characterized by an approximately constant meridional curvature. Large spindles are consequently nearly spherical and small ones practically linear. On standing there appear holes, filled with top liquid, of

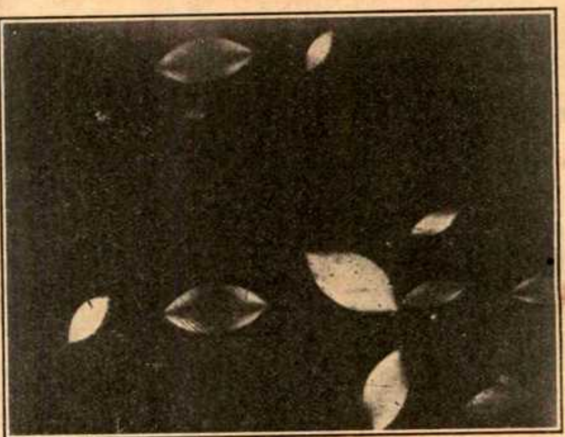

FIG. 2. Highly purified protein from infected sap, when stronger than 2 per cent, separates into two layers on standing. If there is very little of the lower layer, it arranges itself in spindles. Photographed between crossed nicols, × 30.

precisely the same spindle shape. All these phenomena indicate the presence of long fibres.

If any of these liquids be allowed to dry, a film forms on the surface consisting of three sharply distinguishable layers. The first formed is an extremely soft gel well orientated and with much higher birefringence, 0·007, than the liquid. The outer part of this wet gel shrinks by 50 per cent and forms a layer of higher refractive index, but lower birefringence, 0·003. Finally, on placing in air, extensive cracks appear in this dry gel and it becomes translucent and rather feebly doubly refractive. The dry gel is usually well-orientated but in certain conditions shrinks longitudinally to give a herring bone pattern, which indicates that little longitudinal shrinkage of the fibres themselves takes place.

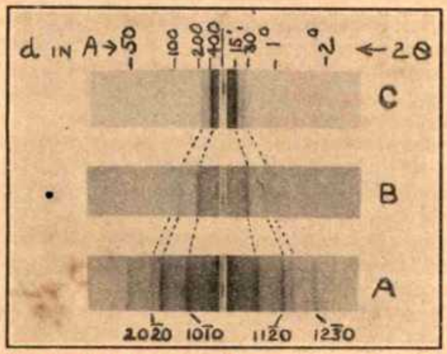

FIG. 3. X-ray patterns of dry gel (*A*), wet gel (*B*) and 13 per cent solution (*C*).

The X-ray patterns of these different forms show remarkable similarities and differences. For the large angle scattering there appears to be little difference, except in general intensity, between patterns given by all the different forms from the top liquid, orientated by flow in a Lindemann glass capillary, to the dry gel and the 'crystals', from ammonium sulphate solutions. This pattern is therefore entirely due to the protein molecules themselves and may be called the intramolecular pattern. It appears to have about the same order of complexity as that produced by feather keratin, with a repeat unit in the fibre direction of 3 × 22·2 ± 0·2 A.

Near the centre of the photographs, spots were observed which varied from one preparation to another. A camera of 40 cm. length was constructed employing an X-ray beam of copper-$K\alpha$ radiation with an angular width of 3′ and capable of showing spacings up to 1,200 A. All the intermolecular pattern so far observed lies in the equatorial plane, that is, refers to the relative sideway positions of the rod-like molecules. The dry gel gives the most definite pattern (Fig. 3) showing five lines (see table) corresponding to the first five possible reflections of a hexagonal close-packing with intermolecular distance of 152·0 ± 0·5 A. The wet gel gives three distinct lines which seem to correspond to hexagonal close-packing with intermolecular distance of 210 A., but this varies slightly with the composition. The bottom layer liquid gives a pattern of three lines; two sharp lines the position of which depends on concentration, indicating a mean molecular distance ranging from 300 A. to 470 A., and a diffuse line at a spacing of 100 A. which is independent of the concentration and is thus plainly of intramolecular origin. The pattern of the liquid suggests that there exists a quasi-regular Debye-Hückel arrangement of parallel rod-like charged molecules in the solution. The sharp difference between the wet and dry gel can best be explained at the present stage by postulating somewhat triangular molecules that fit together in two ways, containing different amounts of water. The reflection at 100 A. supports this hypothesis. So far it has proved impossible to get any indication of intermolecular reflections in the other directions of the molecule, though any regularity of less than 1,200 A. would have been detected. This suggests strongly that the arrangement is regular only in cross-section and that no molecular sheets are formed.

OBSERVED INTERMOLECULAR SPACINGS IN ANGSTROMS.

h k i l	$10\bar{1}0$	$11\bar{2}0$	$20\bar{2}0$	$12\bar{3}0$	$30\bar{3}0$
Dry gel: obs. calc.	131·8 131·8	75·75 76·00	65·90 65·90	49·75 49·75	43·5 43·9
Wet gel	188	106	93		
Liquid: 23 per cent 13 " "	300 397	175 225			

From the results already gained, it is legitimate to make certain conclusions as to the nature of the protein molecules. First, the molecules seemed to be identical in cross-section. Secondly, each molecule has quasi-regular structure and thus may be considered to be built up of sub-units of approximately the same character. The physical properties of the substance can best be explained by postulating rod-shaped molecules. The minimum cross-section area of these is 20,100 sq. A. for the dry gel. The molecular length is more uncertain. The extreme character of the orientation phenomena and the X-ray data point to a minimum length of not less than ten times the width, or greater than 1,000 A. This gives a minimum molecular weight in reasonable agreement with Svedberg's[4] estimate of 17 × 10^6, though there is nothing to show that the lengths of the molecules are uniform.

These results have a certain intrinsic interest, but this would naturally be greatly enhanced could it be shown that these rods are in fact virus particles. This conclusion seems to us both reasonable and probable, but we feel that it is still not proved, nor is there any evidence that the particles we have observed exist as such in infected sap.

Note added Dec. 3.

Wyckoff and Corey have published[5] an X-ray study of the ammonium sulphate crystals of tobacco mosaic and aucuba protein. Their measurements of the intramolecular spacings obtained with unorientated material agree with ours, notably the lines they record at 11·0, 7·44, 5·44 and 3·7 A. correspond to our measurements of the planes (0006, 9, 12, 18) respectively.

Natural Selection

IN NATURE of November 21, Prof. E. W. MacBride states that "Ordinary fluctuating variations which can be graphically represented on a 'curve of error' are certainly not inherited". He bases this statement on the work of Johannsen on pure lines of beans, and of Agar and Jennings on clones of *Simocephalus* and *Paramecium*. He does not mention the fact that Johannsen[1] found clear evidence that such variations are inherited within a mixed population of beans.

Variations of human stature "can be graphically represented on a 'curve of error' ". So can those of human intelligence as measured by the intelligence quotient. Most geneticists are convinced by the work of Pearson and others that such variations are to a large extent inherited. If, as Prof. MacBride holds, they "are certainly not inherited" there can, of course, be no objections to the breeding of the feeble-minded.

If Prof. MacBride is unconvinced by the work of Pearson and Johannsen, I fear that it is futile to ask him to consider that of Gonsalez[2] and Timoféeff-Ressovsky[3], both of whom have described mutant forms of *Drosophila* which are more viable than the normal type in the environments studied by them. Others, however, may take the work of these authors more seriously.

Prof. MacBride goes on to state that "The common flowering plant *Calceolaria* is a native of Mexico and produces bright yellow flowers. As all are aware, gorgeously coloured varieties of this flower are cultivated". A distinguished botanical colleague informs me that 173 species of the genus *Calceolaria* are listed in the "Index Kewensis", of which the great majority are not found in Mexico. They include species with yellow, white and purple flowers. Most, if not all, of the garden varieties have arisen by hybridization. There is no record of mutation within the genus. Hence the fact that, when garden varieties escaped from cultivation in India, only yellow-flowered forms survived, is entirely irrelevant to the topic of mutation. It may be an example of the universally admitted fact that some species of a large genus are better adapted than others to a given environment.

I should be the first to admit that a strong case may be stated against the evolutionary efficacy of natural selection. But such a case must, if it is to be effective, be based on a full acquaintance with the facts.

[3] *Z. indukt. Abstamm. u. Vererb*, **66**, 318 (1934).

IN NATURE for November 21, there appears a letter from Prof. E. W. MacBride in which he attempts to demonstrate that natural selection is not an agent in the evolution of mimetic resemblances. It is perhaps open to question how far statements of personal opinion on evolutionary mechanisms are worth making or answering, unless they are sufficiently detailed to include an analysis of the evidence and reasoning upon which they are based. However, Prof. MacBride's letter contains certain definite errors and misconceptions relating to genetics, and these require correction lest they should gain credence among readers not versed in that subject.

In the first place, it is not correct to state that "Ordinary fluctuating variations which can be graphically represented on a 'curve of error' are certainly not inherited". Even on the most superficial consideration, probably few would agree that the offspring of short or of tall parents may expect to attain the same average stature: and human height in a reasonably homogeneous population is an excellent example of variation falling within a normal curve of error. The fallacy of such a contention can, however, be demonstrated conclusively, for a positive correlation is found to exist between the heights of parents and offspring. Furthermore, the substantial equality of the correlation between the heights of the progeny and of their male and female parents respectively, demonstrates that the inheritance here involved is bi-parental. Finally, the important fact that the F_2 is more variable than the F_1 generation in such a cross shows that we are dealing with particulate, that is Mendelian, inheritance; not with a blending system. The human species cannot, of course, be used to establish this latter point. Reference may, however, be made to much work on such characters in other forms, as that of Castle (1922)[1] on weight, or ear-length, in rabbits.

It is remarkable that Prof. MacBride supports his contention, that "fluctuating variations" are not inherited, by reference to a series of experiments which prove the contrary with particular clearness. This is the work of Johannsen on "pure lines" in beans. Two components may, of course, control the variation of an organism: the hereditary material and the environment. That due to the former is said to be genotypic; that due to the latter, phenotypic. By interbreeding for a number of generations, a "pure line" can be established, in which genotypic variation is practically eliminated. Selection for any characters within such a line is therefore unavailing, since almost all the variation is environmental. It is to this fact, presumably, that Prof. MacBride refers. He has, however, failed to inform his readers that Johannsen was able to establish *a number of distinct pure lines having different average seed weights* (the character which he investigated): thus clearly establishing that the fluctuating variation concerned is under hereditary as well as environmental control in the species which he studied.

Several other points in Prof. MacBride's letter require comment. We now distinguish between the terms 'sports' and 'mutations'. A mutation is the inception of an heritable variation. A sport is any deviation from the normal. This may be due to mutation, or to other causes such as a rare recombination of factors. An overwhelming majority of mutations are disadvantageous: but this does not bar the very types which we study in genetic experiments from representing the kind of changes used in evolutionary progress. Indeed it is precisely what we should expect on this view. Even the more lowly organisms must in reality be rather delicately adjusted. Any random change in their control will consequently very rarely result in harmonious working. Occasionally, however, we may expect it to do so, and this is what we find: as the chromosome doubling which gives fertility to a sterile hybrid (Haldane, 1932)[2], or the single dominant in the moth *Gonodontis bidentata* Cl., which produces a melanic form hardier, and capable of emerging at a lower temperature, than the typical insect (Bowater, 1914)[3].

Mutations may be induced by heat and X-rays, from which Prof. MacBride deduces that they are degenerative changes produced by agents of destructive nature. He does not, however, mention that reverse mutations back to, or towards, the normal are also produced *by these means* (Timoféeff-Ressovsky, 1934)[4]: the agencies which inflict the wound in some instances, heal it in others! Actually, such observations show us that mutations, normally occurring in many directions, are merely increased in frequency by heat and X-rays.

We may well suppose that, in the vast majority of instances, the type best fitted to natural conditions is that occurring in Nature. Furthermore, it is a commonplace of genetics that if domesticated strains are allowed to cross, the normal allelomorphs, separated by artificial selection, may be brought together, reproducing the wild-type condition. Simple Mendelian control of flower colour in *Calceolaria*, and natural selection favouring the wild-type, are all that is needed to explain the interesting instance of "reversion" quoted by Prof. MacBride.

Evidence for Linear Units within Protoplasm

IN his contribution to the "First Report on Viscosity and Plasticity", H. J. Jordan[1] has quoted only the measurements by W. Seifriz on protoplasm in 1924. But L. V. Heilbrunn does not find any conclusive evidence for elastic behaviour, apart from those cases where definite fibrillar elements can be observed in the protoplasm. In some recent papers, I have demonstrated the anomalous flow of protoplasm[2] and determined certain values interpreted as moduli of dilatability, transversal contraction and gliding[3]. Both the anomalous behaviour of protoplasm under varied shearing stresses and its elasticity are dependent on a structural organization of protoplasm not with respect to its grosser parts such as the nucleus, but in regard to the actual chemical molecules of which it consists[4]. So the next task was to find any substantial evidence for fibrillar or linear units within the protoplasm submitted to a stress along a definite axis.

My deformation apparatus[5] consists of a capillary, a water manometer, and a tube with an india-rubber aspirator bulb, the three being united by a *Y*-tube. The protoplasm is sucked up into the capillary. At right angles to the axis of the capillary, a beam of parallel, plane polarized light passes with its optic axis at a given radius through the flowing protoplasm. After crossing the space below the objective, the light passes through the microscope and the analysing nicol. As the light is rendered telecentric by two diaphragms, only beams which run parallel, or almost parallel, to the axis of the microscope can enter the ocular.

In the former experiments, I have used the naked cells obtained from the liquefying pericarps of berries, or other plant cells obtained by means of experimental denudation. With the behaviour of these I have compared cells present in saliva (resembling leucocytes) obtained from the human mouth. Now I have likewise accumulated data using living eggs of freshwater molluscs, such as *Unio* and *Anodonta*, which are useful on account of their frequency and large size. After being isolated from the branchiæ of adult animals, the eggs were immersed in the ovary liquid.

The phenomenon observed between crossed nicols agrees with the assumed structure of protoplasm. If we permit the protoplasm to flow through the capillary, a system of many-coloured interference veins appears parallel to the capillary direction. With increasing speed of flow the interference lines disappear. Near the capillary axis, the flowing speed is greater than near the wall, so the coloured strips here are unrecognizable. The interference veins disappear after the eggs are placed in distinct buffer solutions of increasing hydrogen ion concentrations. In interpreting the results of experiments with eggs of different *p*H, it must be remembered that cells often act much like amphoteric colloids having an iso-electric point[6].

Summing up the results, we cannot be sure that the results obtained are quantitative. To anyone who has surveyed the whole field, however, there can be no question but that in all types of protoplasm hitherto used, fibrils or linear units are really present, although only visible if the protoplasm is flowing through a capillary.

A detailed description of the experiments will be given in a paper being published next year[7].

Mechanism of Chemical Reaction in the Electric Discharge

IN view of the apparent renewal of interest in chemical reactions taking place under the influence of the electric discharge, I venture to put forward the following suggestions, which have not so far been published although frequently expressed at colloquia.

The close proportionality often found, for example, by Dr. Keith Brewer and his collaborators[1] between rate of reaction and current flowing in the outer circuit, has led to theories that positive ions are themselves the reacting bodies, clusters being formed, especially where more than one molecule of reaction product is obtained for each positive ion. Now although mobility data leave no doubt that surrounding molecules can exert a retarding effect upon an ion, to produce an effect which may formally be expressed in terms of ion-clusters, there is complete lack of both spectroscopic and positive ray evidence as to the existence of the reasonably stable aggregates which the theory necessitates. Moreover, it is not likely that the chemical properties of $N_2{}^+$, for example, will be the same as those of N_2, while a process such as:

$$N_2{}^+ + O_2 \xrightarrow[e]{} 2NO + 325 \text{ Cal.}$$

is so highly exothermic as to be incapable of giving the large yields, referred to ion-concentration, which have been reported. This same argument holds for many other reactions, since the ionization potentials concerned are generally of the order of 15 v.

If, however, we are prepared to regard the ions as forerunners of the true reactive species, with further reservations as to the accuracy of measurement of ion-concentration, the above-mentioned proportionality may be explained, as well as the onset of reaction, when controlled electrons are used, at the lowest ionization potential[2]. Once ions have been formed, a variety of processes may occur which cannot be observed while the current is purely electronic. Such processes are:

(*a*) ready dissociation, for example, of N_2^+ and H_2^+, to give the reactive atoms[3];

(*b*) genesis of excited states which may also be reactive or give rise to reactive bodies;

(*c*) formation of fast neutral bodies by the electron interchange reaction

$$A^+ + B \rightarrow B^+ + A,$$

where A^+ and B^+ are the primary and secondary ions[4];

(*d*) production of similar high-speed species by the escape of an ion, after undergoing cathodic neutralization, with a considerable fraction of the kinetic energy which is acquired, while moving in the charged condition, under the influence of the applied fields[5];

(*e*) kinetic activation of molecule by ion, as a knock-on effect[6].

To indicate only some of the apparent advantages of this theory, processes (*c*), (*d*) and (*e*) can account for the influence of cathode material occasionally observed[7], as well as the production of several molecules of reactant for each ion present[1].

In another communication, shortly to be published elsewhere, these views will be further developed and shown to provide a ready explanation for the electrical synthesis of nitric oxide, treated, as is suggested, as an essentially thermal process.

Continuous Absorption Band of Rubidium in the Presence of Foreign Gases

A NEW absorption band has been observed, with a Hilger E_1 glass spectrograph, on the shorter wavelength side of the second member of the rubidium principal series, in the presence of neon, helium, hydrogen or nitrogen. The position of the band depends on the nature of the foreign gas admitted into the absorption tube, which was kept at around 250° C. A pressure of a few centimetres of mercury of the foreign gas was sufficient to make the band appear distinctly. Fig. 1 is a sample spectrum taken when neon gas was present in the absorption tube of rubidium vapour, and Fig. 2 the corresponding microphotometer curve.

The bands due to other foreign gases are more diffused than that due to neon. All of them are partially superposed with the broadened line $5S$–$6P_{3/2}$. The wave-lengths of the maxima of these bands and their widths are given below:

Foreign gas	λ	Width
Ne	4194·5 A.	16 A.
N_2	4183·0	24
He	4182·5	35
H_2	4178·7	38

These bands have certainly nothing to do with those due to polarization molecules of rubidium observed by one of us[1], for the latter do not appear below 300° C. In fact, when the absorption tube was heated to 350° C. without addition of any foreign gas, we observed a band at 4188 A. This band was also observed without change of position, together with the new absorption band due to neon, when the latter was present as the foreign gas with a partial pressure nearly equal to that of the rubidium vapour.

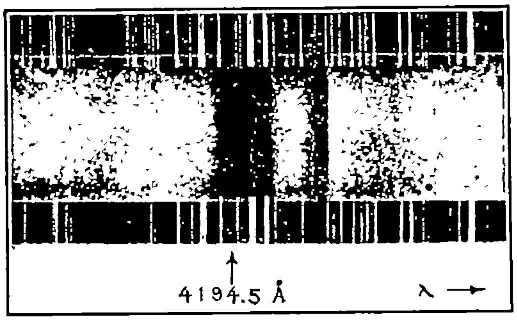

FIG 1.

The narrow continuous band of potassium in the extreme red recently observed by T. Okuda[2] is probably of similar nature. The presence of hydrogen would be necessary for its appearance.

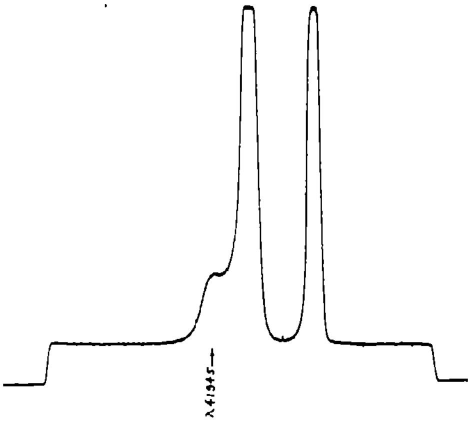

FIG 2.

The existence of these diffuse bands may be explained as due to the inverse process of what has been observed by O. Oldenberg[3] in the fluorescence of mercury vapour with addition of rare gases, the absorption being produced by a rubidium atom at the moment of a collision with a foreign gas atom.

Peking Man

REFERRING to the notes published in *The Times* on November 20 and 28, concerning the recent discovery of two skulls of *Sinanthropus*, I am writing to confirm the fact that the information contained in these notes is correct. (*The Times* has since published, on December 8, an article announcing the discovery of still another skull. The information contained in this later article is now confirmed by letters of Dr. Young and Mr. Chia just received; but I am awaiting further information for details of this fifth skull.)

Since the untimely death, in 1934, of my friend Dr. Davidson Black, the honorary directorship of our Cenozoic laboratory and the investigations of anthropological materials obtained by the laboratory have been carried on by Prof. F. Weidenreich, whose replacement of Dr. Black was recommended by Sir G. Elliot Smith.

In 1935, Dr. W. H. Wong, director of the National Geological Survey of China, of which our laboratory is one department, sent me to Europe expressly to study the Quaternary geology, human palæontology, and Palæolithic industry in Europe, under the personal direction of Prof. H. Breuil. The work in excavation at Choukoutien is carried on by Mr. L. P. Chia, who was appointed by the director of the Geological Survey of China as field director, as successor in my former post. This young Chinese scientist, Mr. Chia, is carrying on his research with patient skill, as a result of which he was rewarded on October 22 by the discovery of a lower left jaw with five teeth well preserved.

On November 16, to the surprise of scientific circles, Mr. Chia discovered two more skulls of *Sinanthropus* in addition to the two skulls which I found on the same site years ago. This site is turning out to be really a treasure house for human science. It is much to be hoped that Prof. F. Weidenreich will be given the three year grant for which he has applied to the Rockefeller Foundation in order to carry on such vital scientific research.

Concerning these two latest skulls, a letter from Père Teilhard de Chardin says, "Two crushed, but largely preserved *Sinanthropus* skulls have been found, some three metres above the Lower Cave and only a short distance from the front of your own excavation, North Wall. The skulls, without any limb bones, were close to each other, and have no lower jaws. The bases of the skulls are missing, as usual. There are one adult male and one adult female. The male specimen will be soon reconstructed, and is more complete than the skull No. 1 all around the calvarium, with even a part of the molar bone preserved. It is difficult so far to appreciate how complete the female skull will turn out to be, but it has at least several parts well preserved: the mastoid area (perfect), a part of the upper maxillary (above the molars), etc. The characteristics are typical, as in skull No. 1, but accentuated. The skulls were found in a place practically barren of bones and implements in a matrix sandy and brecciated in places." A later letter from Mr. Chia adds that the skulls, although badly crushed, will be easily reconstructed, since the fragments were found close together and the breakages are very sharp.

I would like to express my sincere appreciation for the sympathetic co-operation of English scientists, and my gratitude to the Rockefeller Foundation, which has, since the beginning, granted us all the financial support necessary for carrying on our research. In addition to the excellent leadership of Dr. W. H. Wong, director of the National Geological Survey, and Dr. C. C. Young, director of the Peking office of the Survey, we owe much to the co-operation of foreign scientists: Prof. Weidenreich, an excellent and experienced German anthropologist, by whose intensive studies our knowledge of early man in China is being extended and brought to the notice of scientific workers everywhere; and Père Teilhard, the well-known French geologist, whose wide experience has enabled us to carry on work in keeping with recent progress in geological science.

Effects of Chemical Combination with Oxygen and Fluorine on the $K\alpha_{1,2}$-Doublet of some of the Lighter Elements

IT is well known that the $K\alpha_{1,2}$-doublet from the elements 12 (Mg) to 17 (Cl) is influenced by chemical binding, apparent, for example, through its displacement towards shorter wave-lengths. Earlier measurements I have made[1] with the elements 12 (Mg), 13 (Al) and 14 (Si), which were carried out with special regard to the effects from oxygen and fluorine on the $K\alpha_{1,2}$-doublet, have recently been extended by measurements with sodium. No conclusive evidence of any displacement in either direction could be found. These and previous results are summarized in the accompanying table; the measurements on the oxygen compounds of phosphorus, sulphur and chlorine were made by Lundquist[2].

Atomic number	Emitting atom	Maximum valency (p)	Displacement δV (volts)			
			oxygen binding		fluorine binding	
			obs	calc.	obs.	calc.
10	Ne	0	—	0	—	0
11	Na	1	0·01	0·03	0·03	0·06
12	Mg	2	0·14	0·13	0·20	0·22
13	Al	3	0·31	0·30	0·52	0·50
14	Si	4	0·56	0·53	0·92	0·90
15	P	5	0·81	0·82		
16	S	6	1·18	1·19		
17	Cl	7	(1·62)	1·62		

Calling δV the displacement in volts towards shorter wave-lengths and p the maximum valency of the emitting atom, the following equations are found:

Oxygen binding: $\delta V_O = 0{\cdot}033\,p^2$

Fluorine binding: $\delta V_F = 0{\cdot}056\,p^2$; $\delta V_F/\delta V_O = 1{\cdot}68$.

The values of δV calculated from the above equations are given in the fifth and seventh columns of the table, the observed values in the fourth and sixth columns. The discrepancies are well within the experimental errors. The value given for chlorine within brackets refers to the displacement chloride – perchlorate. Provided the equation holds good also for an extrapolation, one would infer from the result that the displacement chlorine – chloride must be very small indeed.

With elements belonging to the second horizontal line in the periodic system the disturbing atom, oxygen or fluorine, is seen to produce a displacement of the $K\alpha_{1,2}$-line which appears to increase as the square of the maximum valency. Considering the highly complicated interaction between the ions or atoms entering into a chemical compound, the simple nature of the relationship just stated is remarkable. Since the above equations were found empirically from measurements, they must be assumed to represent only a first approximation to the exact relationship.

Mechanism of Carbohydrate Oxidation

SOME new facts have been found suggesting that the first stage in the biological oxidation of carbohydrate is its conversion to glucose-6-phosphoric acid (or Robison ester), which is oxidized[1] to 6-phosphogluconic acid. Dehydrogenation by a specific dehydrogenase co-enzyme system yields 6-phosphoketogluconic acid, probably the 2-keto acid, which is then decarboxylated. In animal tissues, where there is evidence[2] that decarboxylation is oxidative, phospho-arabonic acid would result. Yeast carboxylase, which converts keto-acids to aldehydes, would yield arabinose phosphate, as recently suggested by Lipmann[3]. Further oxidation to the 3-carbon systems would then consist in a repetition of these reactions.

Respiration of brain slices (guinea pig, rat) is supported by addition of glucose and, to a lesser extent, of glucose monophosphate, but not by 6-phosphogluconic acid, gluconic acid or 2-ketogluconic acid. After destruction of the cells by grinding with sand, oxidation of glucose is no longer appreciable, but that of glucose-monophosphate, 6-phospho-gluconic acid, gluconic acid and 2-ketogluconic acid is clearly evident. These facts are explicable as follows: (1) the entry of glucose into the cell is accompanied by its phosphorylation; (2) in all the above substances, phosphorylation is the physiological mechanism of their activation; (3) primary oxidation products of carbohydrate are unable to penetrate the cell, whether phosphorylated or not.

Evidence that in yeast gluconic acid is attacked only when phosphorylated is provided by a study of the specific phosphohexonic dehydrogenase. The existence of this enzyme in Lebedew fluid, indicated by the work of Lipmann[3], is proved by its isolation from this source by precipitation with acetate buffer at *p*H 4·6. The washed enzyme may be kept in the dry state. It is active only after addition of both Warburg oxidation co-enzyme (0·04 mgm.) and yellow enzyme, when the oxygen uptake with 6-phosphogluconic acid at 37·5° is theoretical for dehydrogenation to ketogluconic acid. A ketone fixative (0·1 *N* hydrogen cyanide) is necessary, otherwise the reaction ceases after 30 minutes, as with animal lactic dehydrogenase[4]. Co-zymase, active in the lactic system, is inert; gluconic acid is not attacked whichever co-enzyme is used. Purified Warburg *Zwischenferment* contains little of this enzyme, which it closely resembles. Addition of carboxylase[5] causes further oxidation and evolution of carbon dioxide equal to the oxygen uptake. Since this work was completed, a preliminary note by Warburg and Christian[6] has appeared, in which they obtain further degradation of phosphohexonic acid by an apparently different enzyme preparation, hence the publication of this work in its present form.

Both dehydrogenase systems are insensitive to cyanide. In the ground-up brain $M/500$ hydrogen cyanide inhibits reversibly 80 per cent of the oxygen uptake with hexose monophosphate or phosphohexonic acid as substrate. It is concluded that, in biological oxidation of carbohydrate by this system, indophenol oxidase and cytochrome participate. Theorell[7] has shown that H-transport via yellow enzyme – cytochrome can occur. The above experiments suggest that this may be the actual mechanism of carbohydrate oxidation *in vivo*. As yet our attempts[8] to reconstruct the system from heart indophenol oxidase, cytochrome *c*, and the above enzymes, have resulted only in an inhibition of oxidation; other links, possibly cytochromes *a* and *b*, may also be necessary. These experiments are being continued.

I am greatly indebted to Prof. O Warburg for generous gifts of his enzyme and co-enzyme preparations.

Chemical Nature of Citrin

IN a previous note (Rusznyák *et al.*) one of us reported on the isolation and physiological activity (vitamin nature) of the crystalline flavone fraction of lemon juice. The substance, being different from other known flavones, was termed 'citrin'.

Further work has shown citrin to consist of mixed crystals of two different dyes, one being hesperidine (m.p. 261°), the other an eriodictyol glucoside. Hesperidine forms the major part of citrin. The great reactivity and the colour reactions of citrin are due to the eriodictyol glucoside. Citrin contains no free eriodictyol. This substance can be isolated only after complete hydrolysis.

According to its formula, eriodictyol is but a demethylated hesperetine This makes it probable that both glucosides constituting citrin are but two forms of the same flavanone glucoside. Eriodictyol glucoside was not found in any considerable quantity in unripe oranges, which, however, contain great quantities of hesperidine. This makes it probable that the eriodictyol glucoside is formed from hesperidine by demethylation on ripening of the fruit.

This research is being sponsored by the Josiah Macy Jr. Foundation, New York.

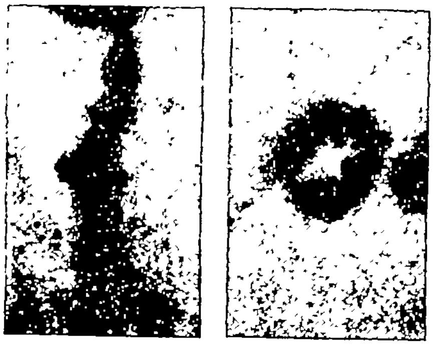
Spiral Structure of Chromosomes in *Osmunda*

THE accompanying photographs (Fig. 1) show the kind of results which are being obtained by application of Sax's method[1] for spiral structure to the meiotic chromosomes of the Royal Fern (*Osmunda regalis*). Both photographs represent gemini at the metaphase of the first division of the spore mother cells; Fig. 1(*a*) is a photomicrograph of a pair of chromosomes united by a single sub-terminal chiasma, Fig. 1(*b*) is a photomicrograph of a pair joined by two chiasmata, one at each end. Both show major spirals of about five coils per chromosome, the two chromatids in each chromosome being in close contact, except at the chiasmata, and occupying the same spiral path.



a *b*

FIG. 1. Photomicrographs of single gemini at the first meiotic metaphase in *O. regalis*, from smears stained in gentian violet. ×4000.

Spiral structure promises to become a cytological phenomenon of very considerable theoretical importance, for it may be a clue to a structural explanation of salient features of chromosome behaviour. For this reason it is particularly desirable that the initial facts should be established beyond dispute, and one of the most essential of these is to ascertain the universality or otherwise of the phenomenon. With few exceptions, the published figures refer to monocotyledonous plants belonging to a relatively small number of families, namely, Liliaceæ in *Lilium*[2,3], *Fritillaria*[4], *Trillium*[5,6], *Tulipa*[7], etc.; Comellinaceæ in *Tradescantia*[8,9], *Rhœo*[1], *Zebrina*[10]; Alismaceæ in *Sagittaria*[11]. Among dicotyledons, details are available for *Lathyrus*[12] and *Vicia*[1] with unfigured verbal reference to a few other genera. Similar verbal reference without figures has been made for one gymnosperm, namely, *Cryptomeria japonica*[10]. A significant widening of the field is thus effected by the addition of *Osmunda* to the list, a plant classed as a relatively primitive vascular cryptogam and with a fossil record extending back to the Carboniferous period.

Fuller details for the Osmundaceæ will be given elsewhere.

Feeding Habits of Stick Insects

THE observations[1] from the Notre Dame Training College, Glasgow, on the eating of dead cellulose by *Carausius*, are very interesting in view of our experience at Strand School, where we have kept stick insects for upwards of twenty-five years, incidentally, without having detected a male.

Ours are fed on green privet, but on occasion, we have tried them with the golden variety, and, while some would eat it quite readily, others refused to touch it, though we never found any difficulty in starting them on it straight from the egg.

We have records of the insects devouring their sloughs, and on one occasion I saw one eating the front legs and antennæ of another insect which had assumed the akinetic condition in which, as is well known, they lose all sense of feeling. This seems worth recording, as it illustrates how a new habit might be formed through the miscarriage, as it were, of a protective device.

Genetics in the Universities

THE essence of a satisfactory course in cytology and genetics is that it should be treated as a branch of biology, rather than as something taken from botany added to something taken from zoology. In a word, the course should be given by a cytologist and geneticist. A composite course shared between a botanist and a zoologist, however sympathetic their co-operation, would be likely to reveal incomplete fusion and to result in overlapping, although admittedly it would be vastly preferable to the two separate and entirely uncorrelated courses often given at present.

The subject matter of cytology and genetics is sufficiently homogeneous yet distinct from other branches of biology (and of sufficient importance) to warrant treatment by a specialist. In a university like that of London, in which I happen to be specially interested, it is unreasonable to expect that every constituent college should possess such a specialist on its botanical or zoological staff, and the obvious solution would appear to be for the University to organize courses dealing with aspects of cytology and genetics from among its teachers as a whole, rather than to leave it to each individual college to provide such courses.

The University of London is in process of acquiring a new central building and now would seem to be an appropriate moment to consider whether the centralization of courses on special aspects of biology should not be attempted, not only on behalf of overworked teachers who are compelled to cope with aspects of their subject on which they cannot speak with authority, but also for the sake of degree students who waste more time in hearing the same subject-matter reduplicated in different courses of college lectures than they would do in attending a coherent course at a common centre.

Aptitudes of the Bantu

THE aptitude of the Bantu when brought into contact with new ideas is sometimes almost startling. One cannot foresee whether he is likely to display remarkable aptitude or stark incapacity. A question, for example, that psychologists might investigate is why the average African native can quickly learn to handle a complicated agricultural tractor or compressed air drill, while the most sophisticated of them seem quite incapable of running a small country store (or general shop) on their own account.

Ten quite ordinary natives in Salisbury, Southern Rhodesia, were induced, as an experiment, to attend classes in Red Cross work and recently sat for their examinations, as first-year candidates. There were five subjects: (1) hæmorrhage control; (2) slings or dressings; (3) fractures; (4) drowning or asphyxia; and (5) transport.

For (1) hæmorrhage control, one got full marks and the average was 76 per cent. For (2) slings and dressings, every candidate's average was 80 per cent. For (3) fractures, two got full marks and the average was 80 per cent. For (4) drowning, and asphyxia, two got full marks and the average was 83 per cent. For (5) transport, six got full marks, three 90 per cent and one 80 per cent.

For the whole examination the best man scored 94 per cent and the lowest 80 per cent.

Judged by any standards, this is a remarkably fine performance and, by the way, also reflects great credit on the Rhodesian Red Cross authorities.

Some New Phenomena produced by Sound Vibrations

Acoustic jets and liquid diaphragms.

USING as a source of sound the singing tube recently shown by me to the Physical Society[1], I have obtained some effects at the interface between a shallow layer of liquid and the gas above it, which do not appear to have been previously described[2].

A glass tube, two or more feet in length, about one inch in diameter, and open at both ends, is slightly curved in a vertical plane so that it may hold a shallow layer of water, oil, or other liquid. When one end of this tube is brought sufficiently close to an open end of the singing tube, one or more liquid diaphragms may suddenly be formed right across the tube. The positions and behaviour of these liquid diaphragms vary with their thickness. Diaphragms five or more millimetres thick are covered with a ripple pattern and appear to be still. Thinner diaphragms erupt a stream of liquid or droplets from both surfaces, while still thinner diaphragms disintegrate in an explosive manner soon after their formation. The formation and breakdown of the liquid diaphragms is often accompanied by 'tides' in the liquid simulating the seiches observed on lakes. The addition of powdered mica to the liquid permits the formation of a semi-permanent membrane across the tube which persists after the sound is cut off

A sonic amplifier and pendulum maintained by sound vibrations.

A short length of glass tubing, closed at one end by a stretched thin rubber diaphragm, when slipped over the end of a sounding Knipp's tube[3], re-enforces its note for a relatively wide range of positions. A position can be found in which a slight touch on the diaphragm stops the sound. If the bob of a bifilar pendulum be allowed to impinge on the diaphragm when it is in this sensitive position, the vibrations of the pendulum may be maintained and the noise of the impacts exalted to the tappings of a drum.

A frequency demultiplication factor exceeding one hundred may easily be obtained with the system.

Adjustable Resonators and Orchestration

THE description of the Hammond organ by Sir James Barrett in NATURE of August 15 (p. 297) prompts the physiologist to ask why orchestration does not yet employ the method of the adjustable resonator so important in human speech and song. A very slight alteration in the calibre of the supralaryngeal passages will make a profound difference in the quality of the voice, as every singer knows. In a few instruments of minor importance there can be found a series of resonators, but these are incapable of change. A good violin player can, by alteration of pressure and of bowing, make some adjustments in the resonance, but the range of such is small compared with the human voice.

One can picture the orchestra of the future placed on a huge resonator with electrically worked pistons, bulkheads and dampers. The conductor, it is true, would have one more score to direct with eye and baton. When on this topic, may I ask if experiments have been made to construct acoustic membranes for reception or emission on the principle of the mammalian ear-drum?

Directions of Homogeneous Auroral Arcs

THE Oxford University Arctic Expedition 1935–36 wintered in North-east Land at 80° 23′ N., 19° 31′ E., where single photographs of the homogeneous auroral arcs were taken in order to determine their direction. The photographs were reduced by the method used by Wesoe[1] and Stormer[2]. Persistent cloudiness prevented many photographs being made, but the average of fourteen measurements was 73° E. of N. for the region 80° N. to 76° N., 15° E. to 40° E. The individual determinations were 84°, 78°, 65°, 68°, 91°, 65°, 66°, 70°, 73°, 67°, 70°, 95°, 85°, 48° E. of N.

I wish to express my thanks to Dr. Harang, who reduced the photographs at the Auroral Observatory, Tromsö, and gave us much assistance.

Nitrogen Fixation with Cow-Dung

WHEN freshly collected cow-dung (containing 0·368 per cent nitrogen and 7·5 per cent carbon) is mixed with soil and exposed to sunlight daily for six hours in dishes, nitrogen fixation is observed. Thus the nitrogen content of a mixture containing 500 gm. soil and 100 gm. cow-dung rose from 0·0905 per cent on July 27 to 0·14 per cent on November 4, 1936.

In field trials, when 25 tons of cow-dung were added per acre, the total nitrogen was increased from 0·052 per cent to 0·061 per cent in a month. When the same amount of cow-dung and 25 tons of molasses were added per acre in fields, the total nitrogen was increased from 0·053 per cent to 0·07 per cent in the same time. Hence cow-dung, which is used as a manure for its content of nitrogen, potash and phosphate, has been found to supply to the soil not only the nitrogen it contains, but also it can add nitrogen to the soil from the nitrogen of the air by fixation. The cellulose and pentosans present in the cow-dung undergo oxidation on the soil surface and liberate the energy necessary for nitrogen fixation.

Points from Foregoing Letters

BY further purification of the crystalline protein preparation having the property of producing the mosaic virus disease in tobacco plants, F. C. Bawden, N. W. Pirie, J. D. Bernal and I. Fankuchen have obtained solutions which (in concentrations greater than 2 per cent) separate into a lower liquid crystalline layer and an upper layer showing optical anisotropy when flowing. The liquids form gels on drying. X-ray investigations show a common pattern corresponding to a 'repeat unit' of 3 × 22·2 A. in the crystal, liquid and gel stage; other features of the X-ray pattern indicate hexagonal close-packing in the gel stage and parallel, charged, rod-like molecules in solution. The authors estimate their length to be greater than 1000 A. and their width about one tenth of that length. This corresponds with a molecular weight agreeing with Svedberg's estimate of 17×10^6. It is not yet conclusively proved, however, that these are actually the 'virus' particles.

Prof. J. B. S. Haldane and also E. B. Ford criticize several of the statements made by Prof. E. W. MacBride when discussing the mechanism of natural selection. Both authors give examples of inheritable variations which can be graphically represented on a 'curve of error', and they claim that the return of the garden variety of *Calceolaria* to the wild type is irrelevant to the topic of mutation.

When protoplasm (for example, cells from human saliva, eggs of freshwater molluscs, liquefying pericarp of berries) flowing through a capillary is observed between crossed nicols, a system of many coloured rings appears parallel to the capillary direction. This, Dr. H. H. Pfeiffer states, is in accordance with the hypothesis of a fibrillar structure of protoplasm.

To explain the close proportionality between the flow of current and the rate of chemical reaction in certain cases of electric discharge, for example, in the formation of NO from nitrogen and oxygen, it has been suggested that positive ions are the reacting bodies. Dr. E. J. B. Willey states that the hypothesis that the positive ions are forerunners of the 'reactive species' explains a larger number of observed facts.

A continuous absorption band observed in rubidium vapour in presence of certain gases (neon, helium, hydrogen or nitrogen) is described by Ny Tsi-Zé and Ch'en Shang-Yi. The position of the band varies with the gas. The authors suggest that the absorption is produced by a rubidium atom at the moment of collision with a foreign gas atom.

Dr. W. C. Pei, who was until recently in charge of the excavations at Choukoutien and is now studying in France, writes to confirm recent reports of new discoveries of material relating to early man in China at the well-known site at Choukoutien (see NATURE, Dec. 12, p. 1004).

A table showing the displacement of the $K\alpha_{1,2}$-doublet in the X-ray spectrum of the lighter elements (magnesium to chlorine), when they combine with oxygen and with fluorine, is given by Dr. N. G. Johnson. The displacements appear to increase as the square of the valency. In the case of sodium the evidence for displacement is not conclusive since owing to its smallness it falls within the experimental error.

Evidence is brought forward by Dr. F. Dickens suggesting that the early stages in the oxidation of carbohydrate are hexose monophosphate, phosphogluconic acid and phospho-ketogluconic acid, the latter being decarboxylated by different routes in animal tissues and in yeast. Phosphohexonic dehydrogenase has been isolated from yeast; it converts phosphogluconic acid into the corresponding keto-acid, and for this it requires Warburg oxidation co-enzyme and yellow enzyme to complete the dehydrogenase system. In the biological oxidation of carbohydrates by this system, indophenol oxidase and cytochrome probably take part, since oxidation of hexosephosphate and phosphohexonic acid by brain tissue is strongly and reversibly inhibited by cyanide.

'Citrin', a physiologically active constituent of lemon juice having vitamin properties, consists, according to V. Bruckner and Prof. A. Szent-Gyorgyi, of a mixture of hesperidine and eriodictyol glucoside.

Photomicrographs showing spiral structure of chromosomes in the spore mother cells of the Royal Fern (*Osmunda regalis*) at the metaphase stage of the sexual nuclear division (meiosis) are submitted by Dr. I. Manton. Similar structures hitherto described have belonged mainly to monocotyledonous plants.

Sidney T. E. Dark records that the common stick insect (*Carausius*), while occasionally refusing to change its food plant, will sometimes inadvertently eat other stick insects in the immobilized (akinetic) condition even in the presence of plenty of its normal food.

Prof. F. L. Hopwood describes the formation of liquid diaphragms in a partly filled bent tube under the influence of sound vibrations, and also a simple sound amplifier consisting of a short glass tube with a thin rubber diaphragm slipped over the end of a Knipp's tube.

Origins of the Russian Population

IN discussing the evidence for a pre-Aryan element in the population of southern Russia, Dr. A. Bachmakoff compares conditions in prehistoric France, where, notwithstanding the evidence of Cæsar, there is reason to believe that the Veneti were a pre-Aryan people, possibly related to the Picts, while in the south the Ligurians and Basques represent two branches of a race which may have extended from the Pyrenees to the Atlas (*Z. Rassenkunde*, 4, 2). In south Russia there is evidence for the existence of a similar pre-Aryan or Japhetic element, upon which the Aryans impinged about 1500 B.C. North of lat. 50° were impenetrable forests inhabited by Finns, but south of this line in the steppe country was a special kind of pre-Aryan population, which appears to be related to that of the Circassians (Kimmerians) of the Caucasus. The Aryans first impinging upon this population were Scyths or Iranians. The Slavs did not move before the Christian era, although it is possible that there were Slavs around Kiev, who were known to the Greeks in 450 B.C. These Proto-Slavs, however, remained quiescent for a thousand years. The effect of this Japhetic element on the Aryans can be estimated at two epochs—first on the Scyths in antiquity, and secondly on the Slavs in the Middle Ages. The first question to be decided is that of the Kimmerians. It would appear that they were a branch of the Circassians, who settled on the banks of the Kouban. They seem to be persistent in Anatolia from the time of the Hittites. The evidence for the existence of this race as a principal element in the substratum of the Russian population is mainly linguistic. The name "Tcherkesses" is found in Kiev. Little Russian names end in *-ko* instead of *-off*. The suffix *oukh*, which appears in Russia, is of frequent occurrence in various forms in names in Asia Minor in antiquity, and there is also evidence for it in Elamite, Mitanni and Proto-Hittite.

Rock-Drawings and Paintings of the High Plains, U.S.A.

IN the course of seven seasons' work, the Archæological Survey of the South-Western High Plains area instituted by the Anthropological Department of the University of Colorado, on the initiative of Prof. E. B. Renaud, recorded a large number of rock-paintings and drawings in Wyoming, South Dakota, Colorado, Arizona and New Mexico, particulars of which have been given from time to time in the reports of the Survey. In the recently issued eighth annual report, Prof. Renaud has brought together and collated the evidence given in these reports, now mostly out of print, and has prefaced the summary description of sites and recorded examples with a general appreciation and discussion of this regional manifestation of aboriginal art, which is not without interest for European archæologists, more especially as it approximates in its conventionalization of representations of the human form to certain phases of the art of the Stone Age in Europe. No very high antiquity is to be assigned to this High Plains art. The cave paintings of the Cimarron Valley, in which representations of the human form with characteristically square shoulders are outlined in red paint, have been assigned tentatively by Dr. A. V. Kidder to the Basket Maker culture, with a possible antiquity of some three thousand years; but as was shown quite conclusively by an inspection made when the Survey was at work in New Mexico in 1929, this group stands outside the field of High Plains art. Subject, style and technique in High Plains art corroborate the chronological evidence afforded by the superposition of paintings and drawings one upon another on the rocks and stones upon which they are found, while the representation of the horse indicates that all but the oldest class cannot be prior in date to 1680–90. As regards the significance of these paintings and drawings of human and animal forms and conventional signs, some are obviously phallic, while others equally clearly show relation to the symbolism of religious belief. The remainder appear to record tribal or personal events, or the occurrence of game and water-holes nearby.

Study of Airmen's Reactions

AN apparatus for listening to the beating of an airman's heart and recording it to the ground, where it can be reproduced on a sound film, has recently been devised by the Medical Aviation Department of the Soviet Civil Air Fleet. The apparatus will enable the physician to study the condition of an airman without having to accompany him in his flight, and also to ascertain the effect of different altitudes on the human heart. The apparatus resembles a small laryngophone or osteophone, and is fixed to the airman's chest above his heart. It is connected with a radio transmitter in the cockpit, which transmits the impulses to a special receiver installed in the ground laboratory, where it is recorded on a ribbon for reproduction on a sound film.

Food of Passenger Pigeon

ALTHOUGH the passenger pigeon has been extinct for many years, the stomachs, with food-contents, of eleven individuals have recently been discovered in the collections of the U.S. Biological Survey (according to a report circulated by Science Service, Washington, D.C., Oct. 21). The food materials were examined by Phœbe Knappen, who records that nine tenths of the items were of vegetable origin, the remaining tenth of animal origin. Acorns formed the greatest part of the food, next came oak-galls, followed by fruits of the pokeberry, a common weed, and grains of wheat. It is suggested that the predominance of acorns and oak-galls points to the disappearance of the primeval forests of North America at the hands of the woodman, as sharing with the activities of hunters, in the extermination of this once abundant bird.

Bee-Keeping in India

ATTENTION may be directed to the appearance this year of a third edition of the bulletin on bee-keeping by Mr. C. C. Ghosh, published by the Imperial Council of Agricultural Research, India (Mis. Bull. No. 6. Delhi: Manager of Publications. 3*s*. 3*d*.). This brochure has helped to stimulate bee-keeping in India besides being used in several other countries. In the present edition not much change has been deemed necessary beyond the incorporation of some new facts about enemies and the hives of the Indian bee, together with the addition of some fresh illustrations. It may be added that while the native Indian bee is easily kept, its yield of honey is much smaller than that of the hive bee in Europe.

Japanese Brachyura

Two papers on crabs from Japan have appeared (*Sci. Rep. Tokyo Bunrika Daigaku*, Section B, 2, Nos. 37 and 39; 1936). The first, by T. Sakai, "Report on the Brachyura collected by Mr. F. Hiro at Palao Islands", describes a large number of species, chiefly inhabitants of coral reefs, mainly from Kororu Island and Iwayama Bay, but some forms usually inhabiting the muddy or sandy shores are also included. There are 36 species belonging to 24 genera, one of the species, *Chlorodopsis* (*Cyclodius*) *palaoensis*, belonging to the Xanthidæ being new to science. Several of these had not been recorded before from Japanese waters. Good photographs are given of a number of forms, but we look forward with interest to the promised work "Crabs of Japan" in which coloured figures are to be published. The second paper, by K. Koba, "Revision of the Specific Name of a Crab as a Second Intermediate Host of *Paragonimus westermani* in Formosa", corrects the identification of the crab *Potamon* (*Geotelphusa*) *obtusipes* (Stimpson) which was found by Nakagawa in 1915 to be the intermediate host of a trematode *Paragonimus westermani* (Kerbert) from the Sintiku District of Formosa. The crab is now determined to be *Potamon* (*Potamon*) *rathbuni*, and the author gives a revised description of the species with figure.

Copepods from the Great Barrier Reef

THE systematic account of the pelagic Copepoda, by Mr. G. P. Farran, is now published (British Museum (Natural History) Great Barrier Reef Expedition 1928–29. Scientific Reports, 5, No. 3. Copepoda. 1936). Further work on habitat, relative abundance, and seasonal and vertical distribution will follow in a separate paper. The species fall into three groups: the reef forms which have their centre of distribution in the shore waters of low salinity, though also often found outside the reef, the open epiplankton, and the deep-water fauna. Of these the first group has been well sampled, but the second and third are not so complete. The greater number belong to the Calanoida—53 from the open sea with 3 new species and a new genus, 37 from deep water with 8 new species and a new genus, and 30 (or 31) from the coastal waters with one new species. The new genus *Tanyshinus* is formed for the new species *T. naro* from the open sea. Its systematic position is in the neighbourhood of *Spinocalanus*, *Mimocalanus* and *Monacilla*. In *T. naro* the rostrum consists of a single stout point with no trace of rostral filaments. As *Monacilla tenera* has a 2-pointed asymmetrical rostrum with one of the points much stronger than the other, it is suggested that a single rostral process might arise by the suppression of the smaller point. The second new genus, *Scolecalanus*, from deep water, is formed for the two new species *S. galeatus* and *S. lobatus*. There are only seven species belonging to the Harpacticoida, the remaining forms being members of the Cyclopoida, chiefly from the open sea. One new genus from deep water is formed for the new species *C. parva*.

Development of the Cotton Hair

ON this subject, Dr. F. M. L. Sheffield has recently published a note of considerable interest (*Empire Cotton Growing Rev.*, 13, No. 4; 1936). This note makes it clear that a state of affairs exists in the outer coat of the developing cotton seed in the early days following fertilization, which has not been sufficiently considered when attempts are made to generalize on these developmental processes. As growth proceeds in the expanding ovule, naturally cells of the epidermal layer continue to multiply and divide, but these dividing cells are interspersed among other cells or cell groups, which are rapidly expanding into hairs, so that fully differentiated and meristematic cells are ultimately interspersed. Dr. Sheffield directs attention to this unusual state of affairs and contrasts it with the apical meristem or the cambium, though it will be recalled that in the cambium there are usually ray cells interspersed between the long cambium initials which are clearly in a different state of differentiation. Hair production in early stages of leaf development is probably also associated with similar appearances in the epidermal sheet. Dr. Sheffield concludes that the amount of variation, associated with hair development, occurring from cell to cell of a single seed and from seed to seed within a single boll is greater than the differences in development between varieties or even between Old and New World types of cotton. Cell divisions were seen in the epidermis of Sakel cotton seeds up to the tenth day after pollination and probably occurred later than this—but the general trend of these observations is to minimize the significance of the exact length of time for which cell divisions were seen and to stress the great variety of conditions of cell development to be found over the surface of the seed.

Gas Storage of Apples

IN view of the increasing interest of commercial growers in gas storage methods, a recent paper by Kidd and West (*J. Pom. and Hort. Sci.*, 14, 3, 276; 1936) is deserving of attention. The experiments described were carried out with Cox's Orange Pippin apples at the Ditton Laboratory over a period of three years. It was found that low-temperature breakdown increased in severity with increasing carbon dioxide concentration, but did not occur at temperatures above 34° F. Fruit stored at 34° F. in September reached the end of its storage life by the end of October whatever the storage atmosphere. Brownheart, which appears early in the storage life, developed most severely in high carbon dioxide atmospheres (15 per cent) and was accentuated by low oxygen, whilst 'core flush' or browning in the core region increased with increasing oxygen concentration. Very little fungal rotting occurred, and this seemed unaffected by the composition of the atmosphere. In general, for long-period storage, minimum wastage from the above causes was obtained with an atmosphere containing 2·5 per cent oxygen and 5 per cent carbon dioxide at 34° or 39° F. The same atmosphere, at 37·5° F. and 39° F., also proved best for the development of the characteristic Cox flavour, which is only fully apparent after the fruit has been removed from store and kept in air at room temperature for a few days. Development of good yellow ground colour was favoured by high temperature and high oxygen concentration, whilst retardation of softening appeared to be due to the effect of carbon dioxide.

Whilst there was some variation in different seasons, it was concluded that the maximum storage life of Cox's Orange Pippin (about seven months) was obtained at 39° F. in an atmosphere containing 2·5 per cent oxygen and 5 per cent carbon dioxide. These conditions cannot be obtained by simple controlled ventilation, but require some means of removing the excess carbon dioxide. It is worthy of note that disastrous results followed the storing of ripe Worcester Pearmain apples along with unripe Cox's, the storage life of the latter being reduced almost to one third, due to the stimulating effect of ethylene evolved by the Worcesters.

Distribution of Earthquakes in the Kwanto (Japan) District

Since the great Kwanto earthquake of September 1, 1923, a network of thirteen seismological stations has been arranged in the district round Tokyo. The quarterly Seismometrical Reports issued by the Earthquake Research Institute give a list of all the earthquakes that were sensible in Tokyo, with, in most cases, the position of the epicentre and the depth of the focus. Two interesting papers, in which the distribution of these earthquakes is considered, are included in a recent *Bulletin* of the Institute (14, 420–426, 427–437; 1936). In the first, Mr. T. Nagata examines the distribution of the foci in two regions in which they are chiefly clustered, the northern part of Tokyo Bay and along the Rivers Kinugawa and Tonegawa. During the years 1924–30, the foci in the former region lay as a rule at depths of 70–80 km.; but, during the years 1931–35, there were few foci at a greater depth than 60 km., showing that the instability produced in the lower part of the crust by the Kwanto earthquake of 1923 is gradually diminishing. In the second region, the earthquakes were most frequent at depths of 40–50 km. in both intervals. Messrs. N. Nasu, T. Hagiwara and S. Omoti deal with the same subject. By projecting the foci in five sub-regions on vertical planes, it is shown that the distribution is funnel-shaped, and that there are two sources at depths of more than 100 km., one below Kumagaya and the other beneath the northern part of Sagami Bay.

Effect of Hydrogen on Photo-electric Cells

In a paper read to the Physical Society on November 27, Dr. N. R. Campbell and R. S. Rivlin continue the investigations on the effect of hydrogen on the time lag of argon-filled photo-electric cells, the results of which were published in previous papers to the Society. In a paper read last April, the proportion of hydrogen required to produce the decrease in time-lag was left undetermined as it was thought that elaborate apparatus would be required. It has been found that the problem can be solved very simply and with sufficient accuracy by using a Pirani gauge. The gauge is of the simple type in which a constant potential difference is maintained across the bridge, and the out-of-balance current is read. The experiments show that all that is necessary is to attach such a gauge to the cell, fill it with argon to a suitable pressure, and carry out the tests by adding or withdrawing hydrogen and plotting the results. When the pressure of the argon in the cell is about 0·2 mm., the effect of introducing a small proportion of hydrogen into the argon, keeping the voltage constant, is to decrease the magnification and decrease the time lag. Both these effects increase rapidly as the amount of hydrogen is increased up to about 2 per cent by volume. The rate of increase then falls off and becomes negligible at about 6 per cent. The exact variation of the effects with hydrogen is complicated and depends on the nature of the cell. It is pointed out that the effects were correlated with hydrogen free in the cell, and that it is conceivable that the direct cause was hydrogen adsorbed on the cathode in an amount which is in equilibrium with the amount free in the cell.

Aetylcholine containing Heavy Hydrogen

It is well known that the pharmacological activity of choline is very greatly increased by acetylation. It is announced in a communication to the Editor by Prof. H. Erlenmeyer, H. Lobeck and Prof. K. Fromherz, University and the Roche Research Laboratories, Basle, that replacement of the hydrogen in the acetyl group by heavy hydrogen yields a product the action of which on the frog's heart is indistinguishable from that of acetylcholine itself, but is about thirty per cent less active on the blood pressure and on leech-muscle. Details of the work are to be published in *Helvetica chimica Acta*.

Ignition of Explosive Gases

G. Mole (*Proc. Phys. Soc.*, 48, 857) has put into a quantitative form the theory of Finch and his collaborators that ignition and self-propagating combustion of an explosive gaseous mixture are determined by the building up of a suitable concentration of excited molecules. A differential equation is set up for the activation and deactivation of molecules. The solution shows that the mixture can remain in equilibrium indefinitely unless a source of activation greater than a critical value is applied. When such a source is applied, an explosion begins after a calculable time The igniting power of a high-frequency source of activation, for example, an electric spark, can be calculated as a function of frequency, and from comparison of this result with experiment, the average life of an activated molecule of carbon monoxide is found to be about 0·4 microsecond.

Thin Metallic Films

Up to the present, it has been found that metallic films only a few atoms thick show no electrical conductivity, and that the resistivity of films many atomic layers thick is much higher than that of the bulk metal. A. C. B. Lovell (*Proc. Roy. Soc.*, A, 157, 311) has succeeded in depositing films of rubidium on pyrex glass which show conductivity when the number of atoms deposited is less than that for a complete monatomic layer The films were deposited by evaporation on a surface which had been cleaned by prolonged heat treatment in high vacuum. The films show a decay of conductivity with time, but this decay became slower with low temperature and thicker films. A film of 40 A. thickness was completely stable at 90° K. The thickest films (up to 90 A.), though still invisible, carried currents up to 0·5 amp. and obeyed Ohm's law, the current density being at least 10^6 amp./sq. cm. The variation of resistivity with temperature and film thickness agreed quantitatively with a simple theory of the shortening of the mean free paths of electrons by collision with the boundaries of the film. The decay of the conductivity of the film with time may be qualitatively explained by the aggregation of the rubidium into islands under surface tension forces. The presence of traces of impurities on the surface influences these surface tension forces and leads to a rapid break-up of the film (see also Nature, 137, 493; 1936).

Wave Forms of Atmospherics at Madras

MR. C. V. RAJAM, writing from the Presidency College, Madras, reports observations on the wave-form of atmospherics received in Madras (13° N. 80° E.) made in the first months of a year's programme. The apparatus used is based on that of Appleton, Watson Watt and Herd, and their eye-and-hand method [now superseded by photography] is used. We are unable to find space to print the report in full, but the following account brings out the principal points.

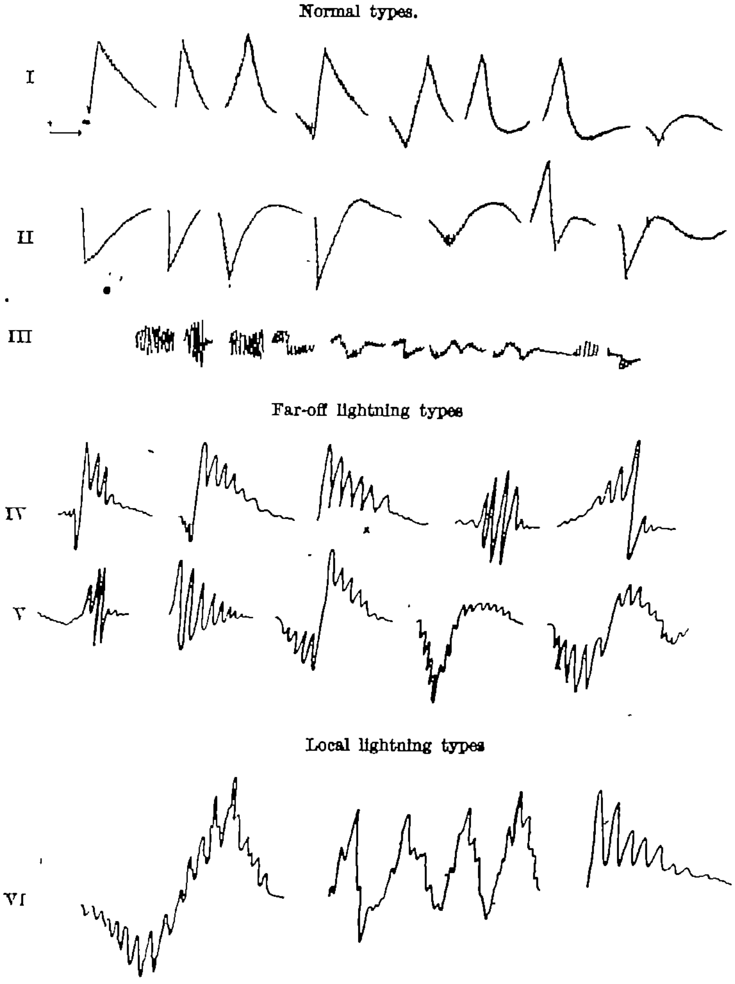

FIG. 1.

Mr. Rajam divides the observed types into three, the normal, the far-off lightning and the local lightning types. These are illustrated in the accompanying figure (Fig. 1). The types shown in rows I and II produce clicks; low-intensity atmospherics of the complicated forms shown in row III produce sustained "frying" sounds. Aperiodic clicks are predominantly negative on 60 per cent of normal days; durations lie between 1,000 and 4,000 μsec. and intensities between 0·1 and 0·3 volts/metre. Short aperiodics of similar intensity have a decay time of 100–700 μsecs. Next in prominence are negative quasi-periodics with a short negative peak of about 0·15 v./m. followed by a rounded positive portion of about 0·05 v./m. peak value; the total duration is 800–1,500 μsec. The most prominent positive type is quasi-periodic, with a brief positive peak followed by a longer rounded negative half-cycle. Here the total duration is 2,000–5,000 μsec., intensity 0·1–0·28 v./m., peak ratio about 6. A small percentage with three half cycles have total durations 4,000–8,000 μsec., intensities 0·2–0·35 v./m.

On 90 per cent of observed forms are found high-frequency ripples of 10–40 per cent relative amplitude; ripple periods range from 25 to 120 μsec., corresponding to frequencies of 8,000–40,000 cycles per sec. A rippled atmospheric produces a jarring click while a ripple-free atmospheric of the same gross form produces a mild click tolerable to the ear.

The "frying" types occur generally in the evening hours, persisting to about 10 p.m., and again before sunrise. They occur in quickly succeeding groups; the group duration is 100–700 μsec., intensity 0·03–0·75 v./m.

With distant visible lightning come the far-off lightning types, rows IV and V. These consist of a close succession of 3–10 impulses of normal type. The most prominent and frequent type (*x* in row IV) has a steep negative rise followed by further impulses on the negative side of the base line. Total durations are 1,500–8,000 μsec., intensities 0·2–0·5 v./m.; 10 per cent show ripple structure of 30–100 per cent relative amplitude and ripple-frequency 8,000–15,000 cycles per sec.

Local lightning types, associated with audible thunder, are shown in row VI. These have durations of 1/25–1/10 sec., intensities 0·7–2 v./m.

The diurnal variation in atmospheric activity on a normal day runs as under. From 1 a.m. to 5 a.m. activity is low, with occasional negative aperiodics. Just before sunrise there is a slight rise, and "frying" type atmospherics appear; just after sunrise there is a marked fall and "frying" ceases. From 8 a.m. to 12 noon activity is very low; until 2 p.m. this state is modified only by the intrusion of low-intensity negative aperiodics and quasi-periodics. From 3 p.m. there is a slow rise to a maximum about 5.30 p.m., with frequent atmospherics. This maximum persists through 6 p.m., with slight decrease to 9 p.m., and an accelerated decrease from 10 p.m. to a midnight minimum.

The work is continuing, and apparatus for automatic recording of wave-forms is under construction.

The Agent of Virus Disease in Plants*

By Dr. John Caldwell

MOST of the detailed work on the nature of the virus agent has been carried out on the virus of the mosaic disease of tobacco. This virus is very easily obtainable in a fairly pure condition, is easily inoculable by rubbing virus preparations into healthy tissues and is resistant to storage and to chemical treatment. This resistance to ageing makes it possible to store the virus *in vitro* in powder form or in liquids over periods of years, and its presence as an active pathogen is easily demonstrable quantitatively as well as qualitatively by the use of the host-plant *Nicotiana glutinosa*, the leaves of which develop local lesions after being rubbed with virus material. It has long been known that there is a definite relationship between the number of lesions and the amount of virus present in the inoculum.

The most outstanding recent development in the study of the virus is the preparation by Stanley of a crystalline protein from the juice of plants infected with mosaic disease. The agent is separable from the crude, expressed plant juice by treatment with protein precipitants, and the virus has an intimate connexion, at the least, with the proteins of the tissues, as evidenced by the effect of pepsin in destroying the activity of the virus and by its antigenic reaction. While it has not yet been clearly demonstrated that the crystalline protein is, in fact, the virus agent in a pure state, Stanley's demonstration of the existence of the virus in the crystallizable protein fraction constitutes a step forward in the isolation of virus [see also p. 1051].

The study of the virus from the point of view of its possible protein nature is complicated by two main factors. It is apparently easily absorbed and inactivated by native proteins and, further, tests for virus activity must be carried out on host plants, since it is the pathogenic effect of the virus which ultimately demonstrates its presence in a given juice.

This biological test requires that, to demonstrate the activity of the virus, there be present no substance which prevents the entry into or subsequent increase of the virus in the host tissues. It has been shown that dead cells do not permit the entry into, or the movement of the virus in, the tissues, and absence of infection in the leaves of the test plant *Nicotiana glutinosa*, in some instances, may be due to the death of cells in the regions of inoculation and not to the absence of active virus. A test has recently been devised which makes it possible to distinguish between an inhibitory effect on the virus itself and a toxic effect on the tissues of the treated leaves. If the inhibitory substance be added in the same concentration to different concentrations of the virus material, that concentration not being too great to prevent lesion formation on the leaves of the host plant at some concentration of the virus, then the effect of the inhibitor will be different if it is acting on the virus, from its effect if the action be on the host tissues. If the action of the inhibitor be on the virus, then its effect will be most marked at the lower concentrations of virus and will be less obvious as the concentration increases until at high concentrations of virus it may not be demonstrable at all. If, on the other hand, the effect of the inhibitor is on the host tissues, the effect will be most marked at high concentrations of virus, when far fewer than the expected number of lesions will be formed, while at low concentrations of virus the effect of the inhibitor may not be demonstrable, since there are comparatively large numbers of possible points of entry of the virus.

The question of the entry of the virus into the tissues has received some attention recently. I demonstrated some time ago that it is possible to inject into the intercellular spaces of leaves large quantities of virus, to spray the leaves of a tomato or tobacco plant with virus material or to immerse the roots in virus juice without subsequent infection of the plant provided the tissues remain undamaged. It was concluded that virus is unable to enter an unbroken protoplast. This conclusion was challenged by Duggar, who reported that if tobacco virus No. 1 material was sprayed with an atomizer on to the leaves of tobacco plants, infection followed, in the course of a few days, entry of the virus being affected apparently through the stomata of the treated plants. In the light of these results, the work on the spraying of tobacco plants with virus material in an atomizer has been carefully repeated and it has been found that no infection was obtained under our conditions even after repeated spraying at three- or four-day intervals, when rigorous precautions were taken to prevent the rubbing of the leaves of the plants and special care was taken in watering them. All plants so sprayed and with one leaf lightly rubbed developed symptoms after only one spraying. This conclusion has been confirmed in a paper published last month by Dr. F. M. L. Sheffield at Rothamsted, whose experiments are reported to show "quite conclusively that the virus is unable to enter uninjured cells".

I have shown that the virus of tobacco mosaic does not travel across areas of dead cells but is confined to the living tissues, and that the weight of evidence suggests a fairly rapid passage along the protoplasmic strands between the cells. I have also shown that there is little evidence that the virus moves mechanically with the main food-streams. This conclusion has been questioned by various workers and further experiments have been carried out to examine this point. Experiments carried out in Exeter have shown that virus activity seems to be associated more with the activity of growing cells than with the movement of materials from the inoculated leaves. Three groups of tobacco plants were used in the experiments. One group was inoculated on the youngest available leaf, the second on a half-grown leaf and the third on the oldest leaf, all the plants being in the 4th–5th leaf stage. All the inoculated leaves were covered with tinfoil or black paper immediately on inoculation. Symptoms appeared first on the plants of the first group, then on most of the plants of the second group and rarely on the plants of the third group. The treated leaves of the first two groups of plants grew rapidly under the covers; while the adult leaves of the third group withered and died in the course of a week. It was evident that the virus could and did move rapidly out of the younger leaves, and that the movement of food materials into them had little effect on the movement of virus out of them.

---

* Based on a paper read on September 11 before Section K (Botany) of the British Association meeting at Blackpool.

The conclusion that the movement of the virus takes place along the protoplasmic strands was confirmed by the observation that the embryo of the seeds of infected tobacco and tomato plants has been shown by the work of myself and others to be healthy and to contain no virus. This may be due to the irregular distribution of virus in the plant tissues and to the absence of direct protoplasmic connexion between the embryo and the parent plant.

The conclusion that the protoplasmic strands are not the paths of movement has also been supported just recently by another paper of Dr. Sheffield, in which she shows that the guard cells of the stomata of *Solanum nodiflorum* do not contain inclusion bodies, while the epidermal cells of this plant on infection with tobacco mosaic virus develop very characteristic inclusion bodies. It has been possible to demonstrate the existence of protoplasmic strands between the epidermal cells of this plant and their complete absence between the guard cells and the neighbouring epidermal cells.

The work on the nature of the virus has opened up some interesting fields for further study. Evidence is being accumulated which indicates that the virus is protein in nature and that it can develop only in living tissues, with which it is intimately connected. This conclusion is of special interest when it is remembered that tobacco virus No. 1 has been shown to exist in some sixty strains, most of which are known to be mutually antagonistic in the plant.

The Electrical Machinery Laboratory, Polytechnic, Regent Street, London

THE newly-equipped Electrical Machinery Laboratory at the Polytechnic, Regent Street, was formally opened on December 10, by Sir E. Henry Pelham, permanent secretary to the Board of Education. The occasion was the jubilee commemoration of the School of Engineering, which first provided an organized engineering training in 1886.

A feature of interest at the meeting was the presence of all three heads of the School, Mr. H. J. Spooner, the first head, who retired in 1922, Prof. A. R. Horne, professor of mechanical engineering at the Heriot-Watt College, Edinburgh, who retired in 1929, and Mr. Philip Kemp, the present head.

The Electrical Machinery Laboratory was first equipped in 1911 when the Polytechnic was re-built, and the machines and apparatus then installed did good service both before and after the Great War. It was realized, however, that if instruction had to be given on up-to-date lines, a thorough re-organization was necessary, and accordingly, plans were prepared for a complete new equipment. The London County Council was approached for financial assistance and a very generous grant was made, enabling the work to be begun in 1933.

The main supply to the Laboratory, which has an area of 4,800 sq. ft., is obtained from the Borough of St. Marylebone three-phase mains at a pressure of 416 volts and a frequency of 50 cycles per second. This is fed to three 20 kva. three-phase transformers in order to step the voltage down to 100 volts, which is the value chosen for the operation of the experimental plant. These three transformers can be operated singly or in parallel, and are each provided with an auxiliary boosting transformer for the purpose of maintaining a constant voltage on the experimental circuits. This voltage is ultimately maintained at a constant value by means of an automatic voltage regulator.

Direct current supplies are obtained from two 15 kw. rotary converters, each with its own transformer. A 540 ampere-hour secondary battery is also available for D.C. work demanding a steady voltage. This battery is connected to the main D.C. bus bars, but has its own separate charging plant. The experimental D.C. supply is taken to a special distribution board, before going away to the various experimental circuits.

The whole of the A.C. experimental supply is brought to a large plug board enabling single-phase or three-phase supply to be delivered to any of the experimental machines at will. If necessary, a particular circuit can be fed from one particular transformer, which can be isolated for the purpose. Signal lights are provided at various points to indicate live circuits.

Instead of using the transformers directly, alternative 100 volt A.C. supplies can be obtained from four 3 kva. three-phase alternators, these also being connected to the main plug board. Two of these alternators are separately driven by two three-phase synchronous motors, a third by a three-phase commutator motor of the Schrage type, whilst the remaining alternator is driven by a D.C. motor.

A feature of the laboratory is the large-scale diagram printed on the wall, showing the whole of the experimental supply circuits.

The four motor-alternator sets mentioned above can be used for experimental purposes as well as for supplying other machines. The synchronous motors of the first two have their stators mounted on a rack and pinion, for the study of load conditions, and they are also each provided with a Joubert contact equipment for wave form investigations.

The D.C. testing plant consists of two 3-h.p. shunt motors, two 3-h.p. series motors and two 3 kw. motor-generator sets, the motors of which can be uncoupled at will.

Converting plant is represented by a 3 kw. three-phase rotary converter and a 3 kw. six-phase rotary converter direct coupled to a 3-h.p. three-phase induction motor, so that the combination can be run as a motor-converter if required. Both these sets are provided with Joubert contacts for wave form work.

Two mercury arc rectifiers are also installed, one being a 3 kw. single phase unit, whilst the other is a 3 kw. six-phase rectifier with grid control.

Alternating current motors are represented by two three-phase induction motors of 2 h.p. and 3 h.p.

respectively, a 3-h.p. synchronous-induction motor, a 3-h.p. three-phase Schrage type commutator motor, and a 5-h.p. commutator motor which can be operated in a number of ways both single and three-phase.

A number of transformers are also available for experimental work of various types, including an equipment which can be used for three- to two-phase transformation.

Oscillatory Discharges in a Magnetic Field

HIGH-FREQUENCY oscillations produced in electrical discharges under the influence of a magnetic field have attracted considerable attention in recent years. In addition to their purely physical interest, they have proved of value to the engineer in the magnetron oscillator, a device which is quite closely related to the cyclotron, or proton accelerator, of Lawrence and Livingston. The secondary emission electron-multiplier of P. T. Farnsworth provides another example of a device in which oscillations can be produced by means of the co-operation of electric and magnetic fields; it differs from the magnetron in that the two fields are aligned instead of being approximately perpendicular.

Prof. T. V. Ionescu has recently described (*C.R.*, 202, 1160 and 1842; 203, 57; 1936) some interesting results relating to a somewhat similar type of discharge tube having a thermionic cathode, two ring-shaped electron-accelerating electrodes and a circular plate which could be given a positive or negative potential with respect to the cathode. A magnetic field was directed along the common axis of these electrodes. (Some results obtained with a similar kind of discharge tube were reported by Prof. K. Okabe recently in NATURE, 138, 685; 1936). Measurement of the voltage-current characteristics of the plate at a gas pressure of the order of 10^{-7} mm. (reported by Prof. Ionescu and Mr. C. Mihul) showed that an electron current could reach that electrode when its potential was below cathode potential (presumably indicating the presence of electronic oscillations) without any magnetic field. The effect of the magnetic field was to increase this current and apparently to split it up into components having different velocities.

In further experiments at a pressure rather less than 10^{-4} mm., a luminous column appeared along the axis of the tube, between the second accelerating electrode and the plate, at a definite value of magnetic field strength. The form of this column varied with the electrode potentials, the cathode emission, and the magnetic field strength, but it apparently did not show the nodes and loops characteristic of ordinary magnetic focusing. The luminous column was found to persist for an appreciable time after the cathode emission was stopped. Electron currents up to several times the cathode emission were observed to flow away from the plate (secondary emission) and regions of negative resistance were obtained.

The tube appeared to be generating powerful high-frequency oscillations, but the available power does not seem to have been determined; the frequencies were of the order of 100–1,000 mc./s. In the last paper, a theory of the oscillations is given which treats them as plasma electron oscillations modified by the magnetic field; two oscillation frequencies then arise in a way reminiscent of the Zeeman effect.

Educational Topics and Events

CAMBRIDGE.—The General Board has recommended that Dr. U. R. Evans continues as assistant director of research in metallurgy for five years from January 1, 1937, or for so long as the Iron and Steel Industrial Research Council continues its grant to the University for scientific research on corrosion, whichever period be the shorter.

It is recommended by the General Board that a readership in plant physiology be established as from October 1, 1936, and that G. E. Briggs (St. John's College) be appointed to that post.

LEEDS.—Mr. Frank Parkinson, head of the firm of Crompton Parkinson, Ltd., and an old student of the University, has given £200,000 for the proposed main frontage to the University in connexion with the reconstruction scheme now proceeding. Earlier this year, Mr. Parkinson gave £50,000 for the establishment of a scholarship fund.

SHEFFIELD.—The following appointments have recently been made: J. L. A. Grout, to be honorary lecturer in radiological anatomy: G. Clark, to be junior assistant bacteriologist; W. A. Timperley, to be research fellow in the Department of Physiology.

DR. H. S. RUSE, lecturer in mathematics in the University of Edinburgh, has been appointed professor of mathematics at University College, Southampton, in succession to Prof. R. C. J. Howland, who died in August last.

THE British Film Institute's third annual report tells of much useful work done and in progress: of answering inquiries from all parts of the Empire; supervising production of thirteen films illustrative of physical training; helping to produce thirteen films for use in the teaching of physics, ecology, and history; publishing a catalogue of British medical films; preparing for the Child Welfare Committee of the League of Nations a report on entertainment films for children, and organizing a conference for discussing the same subject; publishing a new leaflet on non-theatrical apparatus and films for schools; and maintaining the publication of the quarterly *Sight and Sound* and monthly film bulletins. Nine local branches were in operation in England and Ireland, and a Scottish Film Council represents the Institute in Scotland. All this is good so far as it goes, but it must be admitted that the growth in membership has been disappointing. On June 30 there were 597 full and 1,700 associate (branch) members. If any substantial progress is to be made towards realizing the Institute's object "to influence public opinion to appreciate the value of films as entertainment and instruction", its efforts will need to have much more vigorous and widespread backing than they have hitherto received. No local education authority in Great Britain could deny the enormous importance of the objects for which the Institute was formed, and every one of them might well be a full member and help towards the formation of a local branch; but in fact the total number of education committees in Great Britain which have joined is 36.

Science News a Century Ago

Rev. J. B. Reade on Solar Rays

AT a meeting of the Royal Society on December 22, 1836, the secretary, J. G. Children, communicated a paper by the Rev. J. B. Reade entitled "Observations and Experiments on the Solar Rays that occasion Heat; with the application of a remarkable property of these rays in the construction of the Solar and Oxy-Hydrogen Microscope". The method employed by the author for obtaining, by a combination of lenses, the convergence to foci of the 'colorific' solar rays, together with the dispersal of the 'calorific' rays, consisted in making a beam of solar light, after it had been converged to a focus, pass through a second convex lens placed at a certain distance beyond that focus; that distance being so adjusted that the calorific rays were collected into a focus more remote from the first lens than the colorific rays, and consequently nearer to the second lens. By this means, the calorific rays emerged either parallel or divergent while the colorific rays could be brought to a focus which would exhibit a brilliant light without manifesting any sensible degree of heat. The light so obtained could be advantageously applied to the solar, and to the oxy-hydrogen microscope, producing no injurious effects on objects enclosed in Canada balsam or even on living animalcules.

The Rev. Joseph Bancroft Reade (1801–70) was known for his work as a chemist, microscopist and photographer. Educated at Trinity and Caius Colleges, Cambridge, he was successively rector of Stone, Ellesborough and Bishopsbourne. In 1861 he invented "Reade's kettledrum", a hemispherical condenser for the microscope.

Specific Inductive Capacity Apparatus

TOWARDS the end of 1836, Faraday's mind was much occupied with the problem of electrostatic induction. He had been led, by the experiments in electrostatics which he had begun in November of the previous year, to speculate on the mechanism of induction, in particular, as to what was happening in the intervening air or other substance between two opposed conductors. In December he made some experiments with metal plates, charged inductively, to see if the induction measured by an electrometer varied on the introduction of plates of shellac in the space between the conductors.

Although these experiments were inconclusive, he suspected that the induction was affected by the nature of the interposed material, and hit upon a new device to test this, an arrangement of two concentric metal spheres, one within the other, with the non-conducting material or "dielectric" introduced between. The first use of this method is recorded in the "Diary" on December 23, 1836. He says: "Have had two apparatus made for Induction through air and liquids, in which an inner and an outer ball are kept at fixed distances and serve as coatings of Leyden Phials, air being between. They are numbered i and ii and are in all general respects alike. The insulation of the inner ball is by a metallic wire enclosed in a glass tube, the latter being covered well over with lacquer."

This was the famous specific inductive capacity apparatus, still preserved at the Royal Institution. With it, during 1837, he made an exhaustive series of experiments, comparing the induction through gases, liquids and solids such as glass and shellac, which he cast in hemispherical form to fit between the conductors; until he came finally to the conclusion that each of the interposed materials had its own characteristic and measurable capacity for induction, or as we should say, its specific inductive capacity or dielectric constant.

Dr. James Johnson on Health

IN the *Athenæum* of December 24, 1836, is a review of "The Economy of Health; or the Stream of Human Life, from the Cradle to the Grave: with Reflexions Moral, Physical and Physiological on the Septennial Phases of Human Existence, by James Johnson, M.D., Physician Extraordinary to the King". Dividing the life of a man into periods of seven years each, Dr. Johnson said: "the first seven years embrace the *hygiene* of the nursery; the second that of education; the third of the sexual crisis; the fourth of station in life and matrimony; the fifth and sixth of ambition; the seventh may be termed the pathological septennary, or that in which the accumulated venom of numerous petty chronic abuses of health, incidental to a civilized life, break out in positive diseases; and the eighth, ninth and tenth contain the melancholy history of the progressive decline of life, and the gradual breaking up of the effete machinery." In speaking of the seventh septennial, he said, "the immense increase not only of the pleasures, but the pains of existence resulting from a high state of civilization make calls upon the nervous system for a corresponding increase in activity. The result is a morbid increase of sensibility in the nervous system, which operating by sympathy on the nerves of the stomach, liver and other organs, changes their action and deranges their function." The subject, said the *Athenæum*, was investigated by Dr. Johnson "with much acumen and exposed with a vigour of style that is entitled to rank as eloquence".

Melloni's Investigations on Light

"THE Italian natural philosopher Melloni," said the *Athenæum* of December 24, 1836, "has recently invented a mode of depriving the rays of light of caloric, which seems to open the way to great discoveries, respecting the nature of light, thus insulated. His method is very simple: he passes the sun's rays through a combination of transparent bodies (water, and a particular sort of glass coloured green with oxide of copper), which bodies absorb all the caloric, and but little of the light. The light thus separated from its caloric is very yellow with a green tinge; and when so concentrated by lenses, as to be as bright as the direct ray, the most delicate thermometer does not show the smallest degree of warmth. It has long been known that the prism, besides dividing the ray into its several pencils of colours, separated at one end of the spectrum a pencil of heat-making rays, and at the other a pencil of chemically-acting rays, both perceptible only by their effect; but this mode of separating. the heat from the light offered little means of experimenting upon the unadulterated light, of which Melloni's discovery seems to give the philosopher as complete command as he has of the gases, etc."

Societies and Academies

London

Royal Society, December 10.

A. G. MacGregor: Preliminary report on the geology of Montserrat. Montserrat, in the Leeward Islands, is a small member of the series of islands that form the volcanic arc of the Lesser Antilles or Caribbees. The island consists of six mountain masses and hills, each of which represents an old volcano modified by erosion. Active soufrières, emitting hydrogen sulphide gas and steam, have, however, persisted on the flanks of the Soufrière Hills, the youngest volcano, until the present day. Temperatures at the soufrières have remained low from a volcanological point of view during the abnormal gas-emission that accompanied the recent earthquakes. The eruptions of the Soufrière Hills volcano were of the Peléan explosive type, characterized by incandescent avalanches of gases, rock fragments and dust. Part of a large crater with a central "dome" and andesite can still be recognized. True lava flows are found only in the south of the island, where they were emitted from a volcano somewhat older than that of the Soufrière Hills.

C. F. Powell: Preliminary report on seismic observations in Montserrat. An account is given of the results obtained with the Wiechert seismograph and Jagger shock recorders installed in Montserrat in April 1936 by the Royal Society Expedition. The general seismic intensity during this year has been appreciably less than in 1934 and 1935. The monthly number of observed tremors shows a succession of pronounced maxima at roughly six-monthly intervals, the times of greatest activity being May and November–December. The shocks were highly local in origin, most of the foci lying under the island. By comparing the amplitudes of the shocks recorded on the Jaggar shock recorders maintained at different points in the island, the epicentres were found to lie in a broad belt running across the middle of the island. This belt also embraces the active soufrières, but the epicentres are not confined exclusively to the immediate neighbourhood of the active soufrières. A considerable number of shocks originated at a comparatively few "active" foci. Many twin earthquakes, originating at the same focus, were observed. A number of temperature measurements were made, together with observations on the concentration of the hydrogen sulphide and sulphur dioxide.

National Academy of Sciences (*Proc.*, 22, 567–619, Oct. 15).

CLAUDE E. ZOBELL and HELEN M. MATHEWS: A qualitative study of the bacterial flora of sea and land breezes. Wind is an important factor in the exchange of land and sea bacteria. Although many marine forms may survive in the soil, and few terrestrial bacteria survive in the sea, yet exposure of culture plates showed the presence of marine bacteria 30 miles inland, and terrestrial forms 130 miles at sea during relatively calm weather. Bacterial content may aid in indicating the origin and course of large air masses.

L. J. STADLER and G. F. SPRAGUE: Genetic effects of ultra-violet radiation in maize. (1) Unfiltered radiation. Irradiation of pollen greatly increased the frequency of both entire and fractional endosperm deficiencies, and point mutations affecting seed and seedling characters were induced; but no increase in frequency of translocation was observed. (2) Filtered radiation. Radiation of wave-length λ 3130 and longer is relatively ineffective, while λ 3022 and shorter wave-lengths are effective in inducing deficiencies. (3) Effects of nearly monochromatic λ 2537, and comparison of effects of X-ray and ultra-violet treatment. With radiation from a quartz mercury discharge tube, the relative frequency of induced deficiency is about the same as that for longer wave-lengths, but the maximum dose tolerated is much lower. X-rays (1333 r.) produced deficiencies most of which affected the whole endosperm, while a large proportion of deficiencies produced by filtered ultra-violet light affect approximately half the endosperm. The frequency of germless seeds produced by pollen irradiated with X-rays was very much higher than for pollen treated with filtered ultra-violet light.

B. P. KAUFMANN: A terminal inversion in *Drosophila ananassæ*.

TZE-TUAN CHEN: Observations on mitosis in Opalinids (Protozoa, Ciliata). (1) The behaviour and individuality of chromosomes and their significance. In *Zellerella intermedia*, from the rectum of a toad, there are two identical nuclei, each with 24 chromosomes arranged in twelve pairs; the chromosomes are recognizable by constant differences of size, structural peculiarities and position of point of fibre attachment. The behaviour of the chromosomes in cell division is fundamentally the same as that of chromosomes of higher animals and plants. (2) The association of chromosomes and nucleoli. Nucleoli, four, six or more number according to the race of *Z. intermedia* under investigation, are found, each pair occupying a definite non-terminal position on a specific pair of chromosomes. Unlike the nucleoli of higher organisms, they maintain their relation with the chromosomes during cell-division, dividing with the chromosomes. The nucleolar material is considered not to be identifiable with the macrochromatin of the macronuclei of other ciliates.

H. BATEMAN: Progressive waves of finite amplitude and some steady motions of an elastic fluid. A theoretical discussion.

Rearmament and the League of Nations

ALTHOUGH general, but by no means unqualified, support has been given to the Government's programme of rearmament, the impossibility of attaining security in this way alone is fully appreciated by all thoughtful opinion; and much of the support of the Government is conditional upon its efforts to promote collective security and the methods of peaceful change which will diminish the causes of international friction and misunderstanding. Misgivings about the extent of the Government's constructive effort in this field are, however, still apparent.

Unless men are sane enough to recognize that under modern conditions the changed nature of modern warfare makes its renunciation as an instrument of national policy not merely an ideal but also an essential, catastrophe cannot be averted. The most untoward consequence of the present concentration of effort on national rearmament is that it distracts attention from the underlying issues and constructive efforts to find a real basis for peace. Rearmament is at best a counsel of desperation, and no Government to-day has discharged its obligations in the matter of national defence if it has not at the same time explored to the utmost the possibilities not merely of collective defence and security but also of the removal of causes of international friction and of the organization of peace.

The limitations of rearmament, however, are none the less made manifest from time to time, as in the recently published report of the sub-committee of the Committee of Imperial Defence on the vulnerability of capital ships to air attack. While no ship is less likely to be destroyed by air attack than the heavy battleship, the report is on the whole inconclusive. On the high seas, in the main, an air force is still unable to perform the functions of a navy, but the vital question of vulnerability in the narrow seas around the coasts of Great Britain remains undetermined. The sub-committee considers that the day of the capital ship is not over, now or in the near future, but it is clear that while impressed with the vulnerability of the battleship to concentrated air attack under favourable conditions, the Committee merely shrinks from making a decision where the consequences of a mistake might be so serious.

The very inconclusiveness of the report indicates, however, the changed position of Great Britain in regard to defence. Its insularity has gone for ever, and now the ability of the Navy to perform its time-honoured functions can be called in question without instant refutation. Moreover, evidence provided by such a report is very welcome as coming from those the sincerity of whose efforts to secure effective defence cannot be questioned.

This is, in fact, one of the most untoward consequences of the political discussion of rearmament. There is a disposition to assume that those who doubt or deny the possibility of effective aerial or naval defence under modern conditions are anxious to commit the country to the opposite policy of pacificism, and to overlook the extreme dangers which Fascism and militarism offer to the best in man's heritage to-day. Accordingly, Mr. Jonathan Griffin's "Alternative to Rearmament"* is to be welcomed as a vigorous demonstration of a constructive alternative policy which should commend itself to a great body of moderate opinion in Great Britain which, while convinced of the necessity of improving defence, is indisposed to afford the militarists *carte blanche* and realizes that rearmament alone can offer no solution.

---

* Alternative to Rearmament. By Jonathan Griffin. Pp. xii+215. (London: Macmillan and Co., Ltd., 1936.) 6s. net.

Mr. Griffin is under no illusions as to the consequences of rearmament, and quotes comprehensively from authorities to demonstrate the extreme vulnerability of Great Britain to air attack, and the impossibility of any really effective defence. He does not, however, urge that the only policy is one of developing our air forces so as to be capable of rendering instant and equally heavy reprisals. On the contrary, he argues convincingly that to rearm with bombers in this fashion would almost certainly precipitate conflict, and he urges accordingly that our policy should be to concentrate on the measures which would make this country less vulnerable but which would not be construed as a threat to other countries.

On the question of defence without menace, Mr. Griffin makes numerous constructive proposals. He questions the utility of those air-raid precautions which undermine liberty, such as masks and drills, which he stigmatizes as deception, not defence. He urges instead the duplication, dispersal and protection of essential public services and buildings; development of fire-fighting services; exploration of the possibilities of searchlights; the rebuilding or evacuation of great towns; the development of anti-aircraft guns; provision of fighting planes instead of bombers, and above all the adequate organization of the storage of food. If we could store a year's food supply, we should be freed from dependence on the doubtful ability of the Navy to fill its old functions, and in this we should be offering no menace to other countries.

The defence policy advocated thus aims at saving life, not at maintaining morale, and it is insisted that we should avoid measures involving education of the public in passive defence as much as that the policy outlined should be used as an alternative to rearmament. Rearmament should only be permitted on the condition that menacing armaments are definitely limited and co-ordinated for collective security; that there should be no provocation except sanctions against an aggressor; no commitments except the Covenant of the League and a Europe-wide system of collective security against aggression from the air.

On many of these points it is clear that Mr. Griffin is already assured of the support of scientific workers who have devoted attention to this question, and his statement is to be commended to the growing number of scientific workers who are concerned about the prostitution of scientific effort for war purposes and look for some solution which offers a chance of constructive effort for peace and security, and who are prepared to take trouble to sift out the facts from the prejudices in which they are so often embedded.

Many of Mr. Griffin's arguments are underlined in the restatement by Lord Davies of views on the relations of force and law in the light of the unhappy experience of the Italo-Abyssinian conflict*. While he contributes little that is new, Lord Davies, without dwelling unduly on the mistakes of the past, emphasizes the steps which can and must be taken to prevent a like outrage again endangering the foundations of our common security and order. No reader of this book can be blind to the mistakes which Great Britain, though not this country alone, has made, and its failure to render wholehearted and unambiguous support of the collective principle at decisive moments.

Here again is the constructive and practical outlook which scientific workers should welcome. The case for federation and an international police force is set forth with an urgency and relevance which are fresh and effective, even to those familiar with Lord Davies's earlier books. Notably is this true of his discussion of the reform of the League, the present ineffectiveness of which he attributes, after the reluctance of certain powerful members to use the machinery already existing, to the absence of federation in Europe. A new and reformed League must be based on an impartial exploration of the possibilities of the federal system in Europe. Much indeed could be done within the framework of the present Government, and the book contains trenchant criticism of the premature judgment passed on the sanctions system from an experience of its very limited and partial application.

Like Mr. Griffin's book, "Nearing the Abyss" is a challenge to further thought and investigation on vital matters while yet there is time, and both books will indicate fields in which the help of scientific workers is welcome if not essential. Equally impressive is the plea which Mr. C. R. Buxton has recently entered† for an exploration of the possibilities and mechanism of peaceful change in such fields as access to raw materials, population, mandates and the like.

---

Scientific workers who will take the trouble to examine the material now available, in these three books and elsewhere, cannot fail to realize how wide is the field awaiting the application of the scientific spirit and the scientific method, or to find some section of the field in which their own contribution might be made to national defence and security, and the development of that educated opinion upon which alone all constructive effort must rest.

Ancient Buildings in Scotland and England

THE discussion which took place in the House of Lords on December 2, when the question was raised as to the preservation of ancient structures in Scotland and England, while achieving little in the way of immediate action, the motions upon which debate arose being by leave withdrawn, was far from abortive. It served emphatically to direct public attention to an irretrievable loss of material of historic or æsthetic value, especially in Scotland, and in the replies elicited from the representatives of the Government, afforded hope of official support and co-operation in the efforts which are being made to avert further destruction, even though the prospects of financial assistance from the Treasury are not encouraging.

The debate was, perhaps, most useful in clearing the way for further action and in suggesting lines along which further effort might be directed. The problems in the two countries, though very similar, are not identical. Whereas in England the question before the House was concerned only with structures of the eighteenth century, in Scotland material surviving from the whole historic period is affected. In both instances, however, the structures are not 'historic' in the technical sense, or 'country houses', but examples of humbler domestic architecture—a class of building which in both rural and urban areas is of special importance for the cultural history of Scotland, where the strongly marked individuality of the people clearly has been affected distinctively by environmental influences. It was pointed out by Lord Hamilton of Dalzell and other members of their Lordships' House, who supported him, that during the last few years destruction has been taking place in Scotland wholesale and at an extremely rapid rate. "Old Scotland," said Lord Crawford, "is vanishing before our eyes."

The tragedy of this destruction lies in the fact that so often it is avoidable, but is justified as a public improvement, or amelioration of social conditions—road-making or widening and the improvement or extension of housing accommodation for the poorer classes. In Scotland, more especially, Government financial assistance has been made available in a form which has acted as a spur to the destructive activities of local authorities, while the private owner, suffering under a public burden in the form of rates—payable in Scotland on empty property—has sought relief from an expense without return.

In his sympathetic reply on behalf of the Government, Lord Strathcona pointed out methods by which complete destruction of buildings worth preservation might be avoided without forfeiting assistance from the Treasury in certain classes of property, and indicated the extent of departmental supervision already exercised in endeavouring to secure that no historically interesting building should be demolished. The financial obligation, however, involved in any promise of financial assistance from the Government towards the cost of preservation is an uncertain factor, and the delay for which Lord Strathcona asked until the information now being collected by the National Trust is available, though unfortunate, is not unreasonable.

The First Commissioner of Works (Lord Stanhope), in dealing with the position of the eighteenth-century house in England, was less sympathetic, and in suggesting that effort should be directed to persuasion of the local authority, upon whom he sought to throw responsibility, he ignored past experience. For their notorious shortcomings in such matters, local authorities are not entirely to blame; and the time has surely come when the public may be regarded as sufficiently instructed in the value of its ancient treasures to accept the overriding verdict of a Department which speaks with full scientific and technical knowledge. The powers of the Office of Works as a protector of ancient structures should be enlarged to cover in some measure inhabited or habitable structures not contemplated in existing provision.

The Impact of Civilization in Australia

(1) North Australia
By C. Price Conigrave. Pp. 319 + 12 plates. (London: Jonathan Cape, Ltd., 1936.) 10*s.* 6*d.* net.

(2) The Red Centre:
Man and Beast in the Heart of Australia. By H. H. Finlayson. Pp. 146 + 52 plates. (Sydney: Angus and Robertson, Ltd.; London: Australian Book Co., 1935.) 7*s.* 6*d.*

(3) All-About:
the Story of a Black Community on Argyle Station, Kimberley. By Mary and Elizabeth Durack. Pp. 105. (Sydney: The *Bulletin*, 1935.) 3*s.* 6*d.* net.

IN these three books Australia is presented from very different points of view; but the three have this in common—their authors are enthusiastic about their subject, and they succeed in conveying no little of their enthusiasm to their readers.

(1) Mr. Conigrave's book, though by no means heavy in treatment, aims at a more or less comprehensive survey of the history, character and resources of the Northern Territory. The story of its discovery, settlement and exploration, and of its fortunes under the administration of South Australia, are told in some detail, but without tedium. North Australia, as the author points out, is not well known, even to Australians, and lack of understanding has been a handicap throughout its history, which has not been removed entirely in the improved conditions under Federal Government. One great obstacle to development, especially of Port Darwin, is the failure to complete the trans-continental railway. There is still a gap of seven hundred miles between the ends of the northern and southern lines. Nevertheless, it will come as something of a surprise to most readers to find that in 1933 there were still only 3,306 inhabitants, apart from the aborigines. Notwithstanding the development of air traffic, Port Darwin, as the first great port of entry to the continent, has not yet come into its own.

Of the many problems for which the Federal Government made itself responsible when it took over the Northern Territory, that of the aborigines was not the least difficult. There are still some twenty thousand aborigines in the Territory. Mr. Conigrave, while admitting the cruelties and injustice meted out to the aboriginal in the early days of settlement, retorts to the criticisms of the South with the *tu quoque* of the complete extinction of tribes in southern lands. Under the Federal Government and with a changing public opinion, he thinks, the aboriginal has a better chance of a fair deal. While the author allows certain good qualities and abilities to the blackfellow, he is, he maintains, an inferior type, which will answer the irresistible call of the white man's civilization, and then inevitably suffer degradation and ultimate extinction.

Is it true, however, that this fate is inevitable? Anthropological science maintains that study of aboriginal character, abilities and institutions, under sympathetic and understanding administration, will go as far as is humanly possible to ensure that changes are along lines which will develop rather than destroy, and, it may be, provide what will prove ultimately an asset in the economy of the State. It is, therefore, gratifying to note that one recommendation made by the author, the reform of judicial procedure in aboriginal criminal cases, has been carried out since he wrote, on lines which would commend themselves to him, by the appointment of an anthropologist to be responsible for investigation and disciplinary measures in all but the most serious cases of aboriginal crime. Further, the administrative changes now being made by the Federal Government should mitigate the destructive impact of white civilization.

(2) Mr. Finlayson has a story to tell which differs essentially from that of Mr. Conigrave; and the difference is not merely that of environment, although his scene is set in the central desert—the 'Red Centre'. If Mr. Conigrave aims at showing what has been gained for Australia through civilization in the development of a once isolated tropical land, Mr. Finlayson, in his turn, shows how some of the most characteristic features of wild life in Australia are being lost rapidly through civilization, even though in the attenuated form of such settlement as is possible in an arid or semi-arid land. The mammalian fauna is in danger of complete extinction, even before it has been adequately surveyed.

In the hope of arousing a public sense of responsibility in Australia, Mr. Finlayson has written a description of the topographical features and the most distinctive forms of the Mammalia to be found in these desert lands. In order that these mammals may be preserved, he suggests that that part of the central area which is now an aboriginal reserve should be declared a national park. As honorary curator of mammals of the South Australian Museum and a close student of the fauna of the central area—he rediscovered *Caloprymnus*, the Plain kangaroo rat, known previously from three specimens only, which were collected in 1843, and lost to sight since that date—Mr. Finlayson speaks with authority.

Nor are the claims to attention of that most important mammal, man, overlooked. Three chapters are devoted to the people known by the Arunta name of 'Loritja'. The author not only takes a sympathetic view of this people, but also gives them an excellent testimonial for intelligence, good temper and generosity, when in their native surroundings and conditions. This estimate of their character is based upon exceptional opportunities for impartial judgment, when the aborigines thought themselves free from observation and were engaged in their ordinary vocations. His view that the settlers' opinion of the aboriginal is not so entirely adverse as its public expression would convey is probably correct. It is clear at any rate that public opinion is growing slowly in the direction indicated by Mr. Finlayson, who holds that a debt is due to the aboriginal, which must be discharged.

(3) The Misses Durack, members of a family which in 1881 first introduced cattle ranching in the Kimberley district of Western Australia, have jointly produced a book, the one providing the letterpress, the other the illustrations, which describes the aborigines, male and female, who work on the ranch and about the house at Argyle Station. It is an entertaining and valuable psychological study, which at the same time affords an instructive picture of the somewhat remarkable relations between employers and employed. The authors have succeeded in conveying vividly to the reader the aloofness of the blackfellow from the white, even after a long and intimate association, and the completeness of the reversion of the aborigines to the wild state, when they take their 'holiday'.

In these three books, it will be seen, three different views of the aboriginal are presented, which concur, notwithstanding differences of conditions, in ascribing to him some excellences, while taking a lenient view of characteristics and qualities for which he has been condemned. All alike will help to fuller understanding.

Foundations of the New Geography

(1) Elements of Geography
By Prof. Vernor C. Finch and Prof. Glenn T. Trewartha. (McGraw-Hill Series in Geography.) Pp. x+782. (New York and London: McGraw-Hill Book Co., Inc., 1936.) 24*s*.

(2) Geography:
an Introduction to Human Ecology. By Prof. C. Langdon White and Dr. George T. Renner. (Century Earth Science Series.) Pp. x+790. (New York and London: D. Appleton-Century Co., Inc., 1936.) 16*s*. net.

THERE is a certain ruthless analysis, a pitiless perfection of detail as it were, about American scientific writings which leaves the reviewer a little breathless. This is well illustrated in the two works now before us They are almost too thorough. Every *i* is dotted, every *t* crossed; it is the *dernier cri* in university geography. This complete presentation of the subject, so typically American, is nevertheless invaluable to the student. If not exactly inspiring, it is at any rate challenging, which is better. "That," say the authors in effect, "is everything known on the subject. Can you get beyond it?" If the student is content to play for safety, he can come to no harm; but equipped so thoroughly for the fray, the pioneer mind will presently find the weakest link in the iron chain of fact, and push outwards into new fields of learning.

These two books aim successfully at a compact presentation of the groundwork of geography, and supplement one another. The new geography recognizes that the study of land forms has no meaning except in relation to the earth's inhabitants, the ultimate stuff of geography. But the science of land forms, and of the elements which shape them, is essential to an understanding of human environment, which is an aspect of geography too often stressed by people who have no very clear understanding of what human environment is.

(1) Profs. Finch and Trewartha describe in detail the natural elements which affect or produce land forms, the climates and their distribution, and the land forms themselves. In Part 2 of their work the cultural elements of the landscape are described in 30 pages, as against more than 500 pages for the natural elements. Part 3 is devoted to a short description of the geographical *realms*, combining the features already described into a geographical unit.

This method of analysis followed by synthesis is useful, although the correlation between the elements and the finished product might have been carried further. Thus nothing is said of mountain regions in the humid tropical realm, and of the conserving role of the forest covering. In fact, the synthetic portion suffers from over-compression. However, the student should be able to apply what he has learnt in the earlier chapters to any natural region in the world. The book can be recommended to university students.

(2) Prof. Langdon White and Dr. Renner begin where Profs. Finch and Trewartha leave off. The latter incline to the traditional view that geography is the science of land forms, and rather evade the question of what use land forms are—even as an intellectual exercise—apart from the human relationship. The former start with geography as a study of environment, and boldly assert the belief of the neo-geographers, that the human relationship concept is the only justification for geography's existence. They assume a knowledge of the elements which make up the landscape, and plunge at once *in medias res* by describing the climatic realms. These are analysed on the basis of the geographical elements, and are followed by a description of the four principal habitats, similarly treated.

Only at the very end of the book, however, do we find a brief account of man as a serious factor in geography. Considering that the whole book aims at describing man's adjustment to, and activities in, his environment, the last chapter might well have been amplified and put at the beginning. The book is both readable and informative, and lavishly illustrated. It should stimulate students to ponder on the great geographical problems of the near future.

Quantum Theory and Physical Problems

Anschauliche Quantentheorie:
eine Einführung in die moderne Auffassung der Quantenerscheinungen. Von Prof. Dr. Pascual Jordan. Pp. xii+320. (Berlin: Julius Springer, 1936.) 13.80 gold marks.

POSSIBLY the description *anschaulich* in the title of Dr. Jordan's book may tend to deter some enthusiasts for quantum theoretical matters from reading it; since it may be claimed that only macroscopic conceptions can make physical theories *anschaulich* and it is just these which the quantum theory throws overboard. On the other hand, such a description is likely to attract those who, while having no great interest in the quantum theory itself, find themselves forced to know something about its pronouncements on various physical problems.

Of course the attribute of *Anschaulichkeit* belongs rather to the description of the empirical material out of which the theory has emerged and especially to Bohr's correspondence principle which, if a paradox may be permitted, is the most important contribution to the quantum theory and yet no part of it at all. It is the one great and indispensable guide in its development. Though perhaps Dr. Jordan (and even Bohr himself) would insist that the correspondence principle is not merely a heuristic device but an organic part of the quantum theory. Indeed such a claim may possibly be consistent with the 'positivistic' outlook of the author and of many other theoretical physicists, especially in Germany.

The book contains a quite admirable presentation of the main features of the quantum theory written by one of the great contributors to it. The importance of a thorough grasp of classical physical theory for a proper appreciation of quantum dynamics is very rightly emphasized in the very beginning of the book. The former indeed emerges from the latter in the limit $h \to 0$. The early chapters deal with the fundamental experimental deliverances which have given birth to the quantum theory, and with their theoretical analysis. Then follows an account of quantum and wave mechanics with a simple proof of the equivalence of the two chief methods of the quantum theory, namely, that of Heisenberg with its matrix schemes and that of Schrödinger with its proper functions and associated proper values.

The part of the book which follows this deals with 'many-body' problems, with Fermi and Bose statistics, relativistic wave equations, nuclear structure and associated things. Here the author has been forced to squeeze a vast amount of material into too small a space with a consequent lack of clarity. Indeed the whole work is rather condensed and therefore more difficult to read than it might otherwise have been. In particular, the description of Dirac's electron theory is obscure. The author might have given a much better justification for equation (15) on p. 208 than the rather feeble statement that the generalization of the non-relativistic Schrödinger equation can only have the form (15). One wants to know the origin of the $h\,\delta/2\pi i\,\delta x - e\,\varphi/c$ which is so prominent in the equation. And why are there only four of the matrices α ? Why not another matrix α in front of μc instead of $\sqrt{-1}$ in (23) on p. 210 ?

The latter part of the book has a distinctly philosophical character. It deals with the positivistic method, causality statistics and finality and the structure of the real world. No doubt the name positivism is applied to the philosophy of Mach and his disciples because of its resemblance to the philosophy of Comte ; but its most distinctive features are *negative*. It is nearly always *rejecting*, and in the microphysical world it rejects the causality which has dominated science until the present day.

The main epistemological principle of positivism seems to be that which permits only those statements to have a meaning which can be confirmed or denied by the outcome of some actual or conceivable experiment. It has at least one success to its credit. It rejected the ether and thus facilitated the development of the theory of relativity. Many of us, however, will doubt whether this principle is a safe guide, and will prefer the philosophical outlook of Planck, to whose genius and intuition the quantum theory is due. W. W.

Structure and Activities of Protoplasm

Protoplasm

By Prof. William Seifriz. (McGraw-Hill Publications in the Agricultural and Botanical Sciences.) Pp. x+584. (New York and London : McGraw-Hill Book Co., Inc., 1936.) 36*s*.

BROADLY speaking, there are in the field to-day three views of the constitution of protoplasm. While all are agreed that protoplasm is essentially a colloidal system, these views differ as to the kind of colloidal system which constitutes the living substance. According to one opinion, protoplasm is a liquid with a low viscosity and the general properties of a suspensoid or lyphobe system ; according to another view, protoplasm is much more viscous and possesses rather the properties of a multiphase emulsoid or lyophile colloidal system ; while the third view lays emphasis on its elastic properties which bring it rather into the category of gels. The chief exponents of the first two views, Profs. Heilbrunn and Lepeschkin, have already published books dealing with protoplasm and expounding their particular points of view. With the publication of a work on protoplasm by Prof. Seifriz, we have now a reasoned account of the subject by the chief exponent of the third view, which may be summed up in the words of the author : "Though often fluid, and though superficially an emulsion, protoplasm is primarily and fundamentally a lyophilic colloidal system, that is to say, a jelly".

The writer of a book with the simple title "Protoplasm", unlimited by any particular aspect of the subject, has to decide two main points with regard to the scope of the book. One of these is how much knowledge of physics and chemistry his readers may be assumed to possess, the other is how much of what are called cytology and general physiology of the cell should be included. Actually quite a large proportion of Prof. Seifriz's book is devoted to a discussion of certain aspects of physics and chemistry, no less than 17 of the 27 chapters having physical or chemical titles such as "The Colloidal State", "Adsorption", "Viscosity", and it is a question whether most readers of a book of this kind would not already be acquainted with much of the physical and chemical information provided. Certainly most students in England who would want to read this book would have a general knowledge of the properties of colloidal systems, carbohydrates, fats and proteins, and know the meaning of the terms normal solution, electrolytic dissociation, hydrogen ion concentration and *p*H. It seems to the reviewer that all these matters are now so adequately dealt with and accessible in text-books of various branches of chemistry that a book with the title of "Protoplasm" is unnecessarily overloaded with such material when it reaches the proportions it does in the volume under review.

To a less extent the same criticism can be levelled against the book with regard to the quantity of material contained in it which deals with the physiological properties and behaviour of the cell. Thus there are chapters entitled "Permeability", "Electrophysiology" and "Regulatory Substances" (that is, hormones and vitamins), matters which are regarded as part of the province of physiology. Of course, it is quite logical to take the view that the study of protoplasm includes that of its activities, and that on these depend almost the whole of the physiological behaviour of the organism. Indeed, on p. 42, the author writes, at the end of a chapter on cytology : "Such are cells ; with these and the matter that fills them does this book deal". All the same, the subject of cell structure is generally called 'cytology' and that of cell behaviour 'cell physiology'. Moreover, it is not clear why, if a treatise on protoplasm is to have such a wide scope, some aspects of cell physiology, such as those mentioned above, are included, while others, such as respiration, a universal property of living matter, are excluded.

What, then, of protoplasm itself ? The chapters dealing definitely with the subject of the book are the first ("The Living Substance"), the fourth and fifth on "Micrurgy" and "Tissue Culture" respectively, and the fifteenth ("The Structure of Protoplasm and Organic Colloidal Matter"). There are also throughout the book, even in chapters purporting to deal with chemical and physical subjects, constant references to the bearing on protoplasm of the subjects discussed. To the reviewer, the chapter on the structure of protoplasm is the most interesting in the book, for in this the author presents his reasons for regarding protoplasm as possessing a fibrillar structure ; reasons, the forcefulness of which readers must judge for themselves, but which the reviewer must confess he does not find particularly convincing.

The reviewer is mystified by the arrangement of the material in the book ; why, for example, the chapters on carbohydrates, fats and proteins follow, instead of precede, the chapter dealing with the structure of protoplasm.

All the same, if the contents of the book do not fit the title, and if they are strangely arranged, they do comprise much valuable and interesting material. The author states in his preface that the book is written for students of biology and medicine and the related fields of biophysics and biochemistry. Actually, as already indicated, it contains among other material, accounts of physical and chemical principles with which students of physiology should be acquainted, and as such can be recommended to those who require a text-book bringing together necessary information on these matters. The reviewer, however, cannot help feeling that Prof. Seifriz would have rendered much greater assistance to students of biology if, instead of bringing together the materials he has into one book, he had divided it and written two books, one comprising an exposition of the fundamental physical and chemical principles necessary for an understanding of physiological processes, the other a work more strictly confined to an account of protoplasm. The latter might well have included not only a detailed statement of his own views of the structure of the living substance, but also a reasoned criticism of other views of the constitution of protoplasm with which he may not be in agreement.

Bird Migration

Bird Migration:
a Short Account. By Dr. A. Landsborough Thomson. (Birdlovers' Manuals.) Pp. 224+6 plates. (London: H. F. and G. Witherby, 1936.) 5*s*. net.

AN account of a subject with as many ramifications as bird migration can be handled in different ways. Dr. Landsborough Thomson has chosen to present the subject from the impartial point of view of a well-informed spectator. He has neither pet theories to develop nor a personal axe to grind. His treatment is comprehensive in spite of rather severe space limitations, and the vast array of facts is systematically marshalled and logically presented.

The book is quite general and deals with migration in the widest sense. Specific examples of migratory behaviour are not too freely used and are drawn in the main from British sources. Authors are sparingly cited and there is no bibliography. Readers interested in more particular knowledge are referred to a short list of suitably selected works.

The make-up of the book is attractive and its few illustrations are unusually well reproduced. Occasional inaccuracies occur, as in the description of the migrations of the American golden plover. The statement that the spring passage is through the interior of the continent and the autumn passage over the Atlantic from Newfoundland to the Lesser Antilles is only partly correct. Actually it is only the adults that use the latter route in the autumn, while the immature birds proceed south separately through the interior, generally at a later date. It would be nice to see this classical but incorrect account dropped permanently from migration literature, particularly in a book with the merits of this one. The author appears to be over-cautious in his treatment of modern investigations. Even if their final implications are as yet open to doubt, they should at least be mentioned if there is no space to accord them a brief description.

It seems regrettable that interest in bird migration should be largely confined to ornithologists. The present volume, short but dependable and eminently readable, contains much food for thought for the general biologist.

WM. ROWAN.

Handbuch der Astrophysik

Herausgegeben von G. Eberhard, A. Kohlschütter, H. Ludendorff. Band 7: Ergänzungsband, Berücksichtigend die Literatur bis Ende 1934, nebst einem Generalregister des Gesamtwerkes. Pp. ix+756. (Berlin: Julius Springer, 1936.) 129 gold marks.

THE previous volumes of this "Handbook" came out during the course of the years 1928–33. As the articles were mostly undated, the general effect was ragged. This supplementary volume serves three purposes. It gives a common date, the end of 1934, up to which the literature of the separate branches has been considered by the writers of the articles, it covers the recent developments of the subject-matter and it fills gaps in the earlier discussions.

The same subdivisions of each chapter are followed as in the earlier volumes, new items being indicated by placing letters *a,b,c,* after the number of a paragraph. The practice of different contributors in distinguishing new topics from additional or supplementary material has varied; still, the affixed letters do direct attention to the most recent developments in the subject. It is significant that in the section on photometry there are 48 new paragraphs and only 18 supplementary ones. In this section there is no reference to recent work on the profiles and central intensities of spectral lines; these are only referred to in the appropriate sections dealing with the sun and the stars, but in view of the amount of work done since 1929, one would have expected some notes in the section on spectral photometry.

It is impossible to mention all the thirty articles in a short notice, but we can note in that by Dr. Wurm on band spectra an interesting new section on astrophysical applications. In two articles, on the "Thermodynamics of the Stars and Pulsation Theory" and on "The Ionization in the Atmospheres of Celestial Bodies", Dr. Bengt Stromgren has given a full account of recent work on stellar interiors and radiation, having to blend in his treatment references to the articles of Prof. Milne and Prof. Pannekoek in the earlier volumes.

In rounding off various topics and in giving a combined subject-index, this supplementary volume adds appreciably to the value of the earlier parts of the "Handbook", and the editors are to be congratulated on bringing a long and arduous task to a worthy conclusion.

The Earth's Magnetism

By Prof. S. Chapman. (Methuen's Monographs on Physical Subjects.) Pp. xi+116. (London: Methuen and Co., Ltd., 1936.) 3*s*. 6*d*. net.

THE phenomena comprised under the general head "Terrestrial Magnetism" are important, and their explanation is still far from complete. A concise account of present knowledge of the subject was needed. From the hand of one who himself has contributed largely to recent advances such an account is doubly welcome.

In his small monograph, "The Earth's Magnetism", Prof. Chapman has attempted at least to touch upon all material points, leaving amplification of details and theory to a more extended treatise which is already planned. A relatively large amount of information is given, however, about effects of solar and even of lunar origin, the existence of which has been demonstrated by laborious statistical treatment of observatory records and could not otherwise be revealed. The inclusion of a number of illustrative diagrams is helpful in this section. The author's terse and graphic style matches the compact form in which the subject is presented. Readers will find themselves carried on from page to page with absorbing interest.

A few typographical errors in formulæ await correction in subsequent editions; while the method of measuring horizontal force by the Schuster-Smith coil-magnetometer, described on page 7, should be restated, as it differs in a fundamental particular from the method actually proposed by Schuster and employed in the instrument. W. M. W.

Annual Survey of American Chemistry

Vol. 10, 1935. Edited by Clarence J. West. (Published for the National Research Council.) Pp. 487. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1936.) 25*s*. net.

THIS volume presents an interesting view of the progress made in certain branches of pure and applied chemistry in the United States during 1935. The fact, however, that it deals only with the work of one nation, limits its usefulness as a guide to the advancement made in any particular subject, and leads perhaps to a somewhat distorted view. Nevertheless, it provides an excellent résumé of the activities of American chemists, and moreover supplies a comprehensive bibliography of their work.

The subject matter is divided into twenty-five chapters, each compiled by an expert in the topic under review. For the most part, these are well written, interesting and readable, even although the space available necessitates considerable compression and permits of only a brief summary of the many contributions made in each section. Thirteen of the chapters deal with pure chemistry while the remainder are devoted to industrial chemistry. Included in the latter is a chapter on chemical economics which, like one or two other sections, covers a longer period than one year. G. R. D.

The Little Wolf:

a Story of the Coyote of the Rocky Mountains. By Wendell and Lucie Chapman. Pp. xii+140+31 plates. (London: Charles Scribner's Sons, Ltd., 1936.) 6*s*. net.

No one can have travelled in the western States of America without having become more or less acquainted with the coyote. But whether one has done so or not makes little difference to the enjoyment of this book, which is a true piece of nature study at its best. The authors have spent years in the uninhabited sections of the western part of the United States and Canada, and have been able to make friends with the shyest of wild creatures, observing them at work and play, and finally enlisting the help of the camera. Both the story and the illustrations are excellent.

Theory of Complex Atoms[*]

INTRODUCTION

THE structure of complex atoms forms one of the main fields of application of quantum mechanics to many-body problems. The subject has two main aspects: the outer electronic structure, taking the nucleus as a point charge; and the structure of the nucleus.

In considering the outer electronic structure in non-relativistic approximation, which is sufficient for evaluating the main features of the structure of all but the heavy atoms, the forces involved are known, so that an exact wave equation can be written down, and the only difficulty, though a formidable one, is to obtain a solution of it. In the relativistic treatment of the electronic structure, there is the additional difficulty that the exact interaction between two electrons is as yet unknown, so that no exact wave equation can be written down; whereas in the nucleus the quantitative behaviour of the forces concerned are almost entirely unknown, and even their nature is still uncertain.

QUANTITATIVE EVALUATION OF ATOMIC STRUCTURES IN NON-RELATIVISTIC APPROXIMATION

The calculation of atomic properties usually involves a knowledge of the atomic wave functions, and the first step is therefore the evaluation of such wave functions; no exact solution of the wave equation of a many-electron atom is known, and one has to be content with an approximation. The 'solar system' type of approximation, in which the mutual interactions of the electrons are first neglected, and later introduced as a perturbation, is too crude to give significant quantitative results.

A simple type of approximation is to reduce the many-body problem to a set of one-body problems by regarding each electron as being in the field of the nucleus and some average of the field of the other electrons. This type of approximation had already been found to be qualitatively, and roughly quantitatively, successful in the days of the old quantum theory; wave mechanics made it possible to apply it much more precisely, and led Hartree[1] to the idea of the 'self-consistent field', in which each electron is considered to occupy a definite wave function in the field of the nucleus and of the average distribution of charge of the other electrons. In so far as the description of the structure of an atom in terms of occupied one-electron wave functions is significant at all, the electrons cannot really be ascribed each to a specific one of the wave functions, but account should be taken of the possible exchange of electrons between them in obtaining the average field of each electron; this improvement was carried out by Fock[2].

The solutions of the differential equations of the self-consistent field, either with or without exchange, have to be evaluated by numerical integration. Solutions of the equations without exchange have been carried out for a number of representative atoms up to mercury; the solution of the equations with exchange presents a much more formidable problem of numerical technique, but has been carried out for several atoms up to copper.

Another, more analytical, approach to the determination of approximate wave functions is provided by the variation principle, which also provides a criterion for comparing two approximations, without knowing the exact wave function. This principle states that the value of a certain integral expression, involving an arbitrary function, is an absolute minimum when evaluated for the wave function of the normal state, and has certain minimal properties for that of any excited state. It can be applied to the determination of the best approximation of any particular form to the wave function of an atom in two ways.

One way is to take for the whole atom a wave function constructed in a definite way out of adjustable *functions* of the variables of the system; the variation principle then leads to differential equations for the unknown functions. This method was used by Fock[2] to derive the equations of the self-consistent field with exchange, and shows that the solutions of these equations provide the best possible wave functions for the whole atom that can be obtained, so long as the structure is regarded as consisting of a number of one-electron wave functions each occupied by an electron.

The other way is to limit the functions to specified analytical forms (usually sums of products of exponentials and polynomials), with adjustable *parameters* whose best values are determined by the appeal to the variation principle. This method has been used by Zener[3] and others[4] to obtain

---

[*] A review of a group of papers by Prof D. R. Hartree, F.R.S., Dr. B. Swirles and Dr. H. S. W. Massey, read to Section A (Department of Mathematics) of the British Association at Blackpool on September 14.

The general impression created by the fauna is that it represents the Upper Pleistocene period (Gamblian Pluvial period). In Kenya the fauna of the Gamblian Pluvial is known to consist mainly of living species with a few extinct ones, among which is *Bos bubalus*, and an extinct antelope. The presence of rolled teeth and bones of the older fauna cannot be used for dating this deposit because they are obviously derived fossils. Prof. Detreich has examined the fauna since I left Berlin, and has confirmed the views expressed above.

CULTURE OF THE REMAINS

Associated with the fauna described above was a large series of stone artefacts, the majority of which are unrolled and of apparently the same date as the unrolled fauna. Careful examination of every specimen showed that the culture was essentially of Levalloisian type. There are many 'tortoise cores', some of them having had Levallois-type flakes struck from them and some of them having been prepared but unstruck. With these cores are large numbers of absolutely characteristic Levallois flakes with faceted striking platforms. Only two or three pieces, however, show any signs of secondary retouch.

Compared with Levallois material from elsewhere in East Africa, my own impression is that the assemblage represents a stage of development similar to that which occurs in deposits which can be dated to the early and middle part of the Gamblian Pluvial period. The evidence of the culture thus corroborates the Gamblian age suggested by the fauna.

Associated with the Levallois assemblage were a very few broken Acheulean hand-axes, as well as many lumps of lava. Personally, I am inclined to regard these few broken hand-axes as having been picked up and brought to the site with the rough blocks of lava as raw material for making the artefacts of Levalloisian type.

THE SKULL

The skull, which is unrolled, and in exactly the same state of fossilization as the unrolled faunal remains described above, was represented by numerous fragments, and before it was possible to examine it, Prof. Reck had to fit the pieces together so far as possible. It was my good fortune to assist in this task; many of the fragments fitted perfectly, and when fitted together they were found to represent:

(*a*) the greater part of the left parietal;
(*b*) the greater part of the occipital;
(*c*) the greater part of the left temporal including the mastoid and petrous portions.

In addition, several further fragments fitted together to form a part of the frontal bone, with which were associated two fragments from the supraorbital region; these, however, *did not have any direct points of contact* with the rest of the broken frontal. On the other hand, the occipital, left parietal and left temporal bones fortunately articulated perfectly along the sutures, so that their relation to each other was clear. All the bones are very thick compared with the comparable parts of a modern skull. Figs. 1 and 2 show the result of the preliminary reconstruction, which may be regarded as reasonably accurate so far as these three portions of the skull are concerned, owing to the fact of articulation along the suture lines.

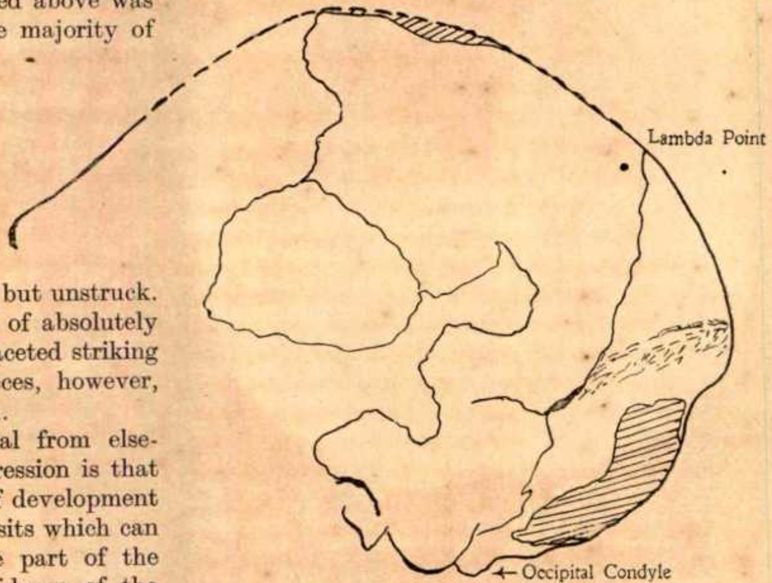

FIG. 1. Profile drawing of the Eyassi skull, based upon photographs. × ½.

The skull presents certain remarkable features. First, the *foramen magnum*, part of which is fortunately preserved, is inclined backwards at an angle comparable to that found in the great apes and quite unlike any *Homo*. Secondly, when viewed from the back, the greatest width of the skull is seen to be in the region of the mastoids, and the form is thus one which approaches that found in *Sinanthropus Pekinensis* rather than any other known human skull. Thirdly, the external occipital crest is very strongly marked, but is smooth and rounded in form. Unfortunately, the fragments of frontal bone which fit together do not have any point of contact with the parietal, so that their exact relationship to the rest of the skull can only be guessed. What is, however, important is that the fragments of supra-orbital show clearly that the skull had a torus (Fig. 3) not unlike that in *Sinanthropus*. One of the fragments is from the region of the glabella and the other from the right external orbital angle.

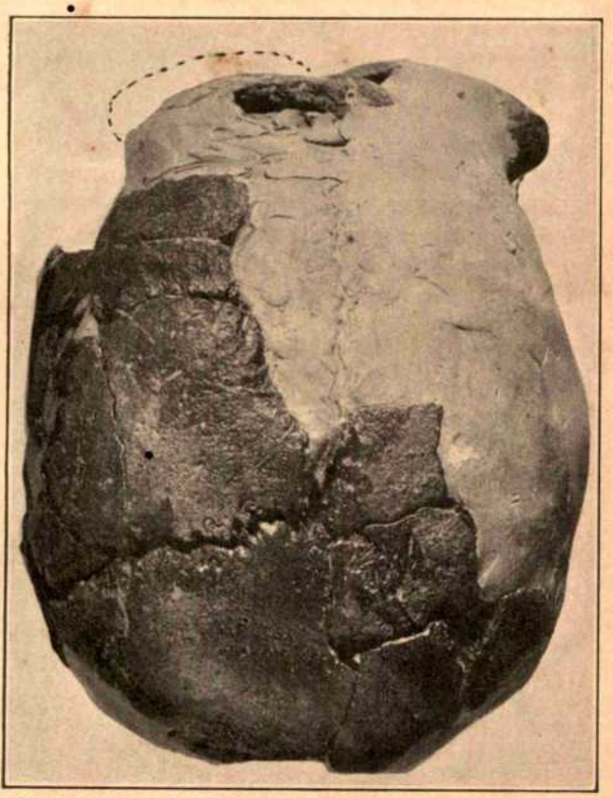

FIG. 2. The Eyassi skull fragments set on a rough block of plasticene. (Owing to tilting, the front is foreshortened.) × ½.

In addition to the parts already mentioned, there is a fragment of the left maxilla which contains the broken sockets of the two incisors, the left canine and first premolar teeth, and the broken socket of the second premolar. There is also a loose upper (first ?) molar of which the roots are somewhat damaged. (It should be pointed out here that in the illustrations published in *Forschungen und Fortschritte* of September 1, this molar tooth is shown in the position of the second premolar, having been mistakenly fitted into the broken socket of that tooth.)

The teeth are well worn and have several remarkable characters, but all that need be said at present is that the canine is of human rather than anthropoid proportions and form, and that there seems to have been no diastema between it and the incisors.

One other small fragment, which does not, unfortunately, fit on to the major portions of the skull, deserves special mention. This is a part of the tympanic plate from the right side (that on the left side is broken away although the rest of the left temporal bone is more or less complete) which is remarkably like that of a chimpanzee, and quite unlike the form found in *Sinanthropus* or, so far as I know, in any *Homo*.

SUMMARY OF PRELIMINARY CONCLUSIONS

Dr. Kohl-Larsen has undoubtedly discovered an exceedingly interesting and very important new document relating to early man. The skull represents a low type of human with some markedly anthropoid characters (the angle at which the *foramen magnum* is set, and the nature of the tympanic plate, for example) while in other ways it approximates more to the type represented by *Sinanthropus* than to any other known human fossil. In a preliminary report by Prof. Reck and Dr. Kohl-Larsen, it is attributed to the genus *Palæoanthropus*, but my own view is that it will have to be accorded new generic rank, although it doubtless belongs to the palæoanthropid branch of the human stem.

This new East African skull is associated with a stage of the Levalloisian culture and with a fossil fauna which both strongly suggest an Upper Pleistocene (early or middle Gamblian) date.

Quite apart from the fact that the skull represents a new genus of man, it is of the greatest importance because it once again demonstrates the association of the great Levalloisian-Mousterian culture complex with that branch of the human stem which is characterized by a massive torus and other specialized features which are never found in any *Homo sapiens*, but are typical of the palæoanthropid branch of man. It is also of particular importance because it demonstrates still further the already established fact that during the Pleistocene period (and even the Upper Pleistocene), the human family was represented in the world by a number of distinct genera and species, of which only one, *Homo sapiens*, has survived.

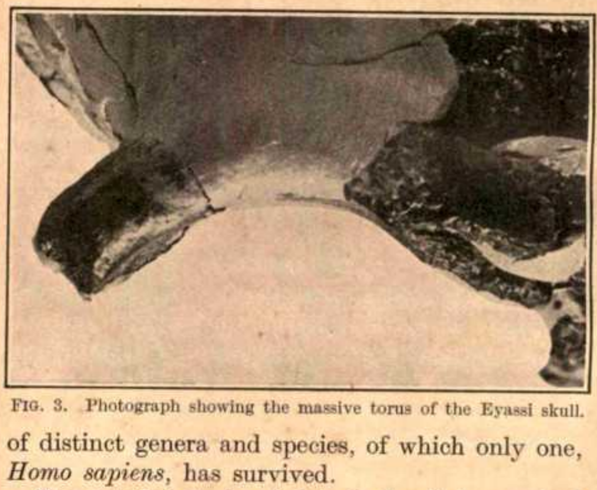

FIG. 3. Photograph showing the massive torus of the Eyassi skull.

The detailed study of this skull will be awaited with the greatest interest.

The Imperial Cancer Research Fund

THE thirteenth report of the British Empire Cancer Campaign was dealt with in NATURE of December 12. We have now received the thirty-fourth annual report of the Imperial Cancer Research Fund*. The Fund began in 1902, and its activities have been in the main devoted to the experimental study of cancer in its own laboratories; besides being one of the first, it has earned its position as one of the leading organizations for the study of malignant disease, and the high quality of the work done under its first two directors, Dr. E. F. Bashford and Dr. J. A. Murray, has been generally recognized. The Fund is under the direction of the Royal Colleges of Physicians and Surgeons, and it has until now been housed in their Examination Halls on the Embankment and in Queen Square, London; more room is now needed, and a new building is to be put up at Mill Hill with plenty of spare land leased from the Medical Research Council. When the cause and cure of cancer have been ascertained, the Royal Colleges will have the duty of diverting the endowment to some other line of medical research; meanwhile, there is no reason for supposing that the new director, Dr. W. E. Gye, and his assistants will not have their hands full with the multiplicity of work in various directions into which modern cancer research has developed.

The present report details sound progress, though Dr. Gye has nothing sensational to announce. He stresses the necessity of distinguishing between two categories of 'causes' of cancer which are sometimes confused. There is first the nature of the intrinsic cellular change which confers upon a cell the property of malignancy, that is, its dissociation from functional relationships with the rest of the body and its capacity for continuous and autonomous growth. The factor which produces this change resides in the cell, and cannot be attributed to external agents; it is the proximate cause of cancer and we know little about it, but seeing that in essential characters all malignant cells are alike, we may surmise that the nature of the change is always the same. It may, however, be preceded by a number of remote causes of diverse nature which bring about the fundamental intracellular change—radium, X-rays, many chemical substances, etc.—and of these we now have fairly extensive knowledge which, if it tells us little about the nature of malignancy, enables us on one hand to prevent some cancers in man, and on the other to produce fresh tumours in animals for experimental study. Another general point brought out in several places in the report is the importance of constitution or diathesis, which comes out clearly now that more precise methods of starting tumours are available, and it seems that this concerns particular organs rather than the animal as a whole.

Much attention has naturally been paid to the virus tumours which can be transferred from one animal to another by cell-free extracts. Attempts to repeat McIntosh's observation that fowl tumours produced by chemicals could be transmitted by filtrates all failed, but it was found that such cell-free extracts injected into rabbits would, equally with tumour tissue, excite the appearance in the blood of a capacity to neutralize the virus of the Rous sarcoma. Since the same chemical (tar, dibenzanthracene, etc.) will induce tumours in mammals as well as birds, it seems likely that something like a virus can be evoked from all cancers. The whole question is at the moment extremely complicated. The effect of radium has also been further investigated, especially by the study of its action on various enzyme systems: it appears that radiation inhibits the utilization of carbohydrates by the cells, which are driven to get their energy from proteins.

The report also announces that the Duke of Bedford has felt compelled to resign from the office of president after more than thirty years service, and that he will be succeeded by Viscount Halifax.

SIR BASIL MAYHEW, vice-president, presiding at the general meeting of the Imperial Cancer Research Fund held on December 15, stated that the new building at Mill Hill will cost £20,000 and a further £10,000 will be required for equipment. The Fund has £11,000 in hand; it requires £19,000. Referring to the relationship of the British Empire Cancer Campaign to the Imperial Cancer Research Fund, he said that the latter has raised large sums, and its policy is to use them in endowing and supporting institutions and individuals engaged in research work. Many of those to whom such grants have been made by the British Empire Cancer Campaign have been supplied with scientific material by the Imperial Cancer Research Fund. By this means, investigators have been enabled to start on their researches at a stage far in advance of that otherwise possible. Advice and suggestions are given whenever asked, facilities are given for research workers to use the Fund's laboratories, and tests are undertaken of cancer 'cures'.

Obituary

Dr. W. Schmidt

THE news of the death on November 27 of Dr. Wilhelm Schmidt, the director of the Central Institute of Meteorology at Vienna, comes as a great blow to his friends and colleagues in meteorology and geophysics. Many of us had seen him recently at Edinburgh at the meeting of the International Union of Geodesy and Geophysics, quite recovered from his illness, keen and interested as always, full of energy and to all appearances with a long period of active scientific work still before him.

Wilhelm Schmidt was born on January 21, 1883. His forbears, as his name indicates, were smiths, in a village some 12 km. from Innsbruck. His grandfather, a man of great courage and determination, decided to go to the University at Innsbruck to study, and began to walk there and back every day, working in the smithy before he started and after he got back. Schmidt may be said to have inherited from him his determination and his capacity for work.

After an education at the University of Vienna, Schmidt entered the Central Institute for Meteorology and Magnetism and was appointed assistant in 1909. I first met him there at the beginning of 1909 when Trabert was director and Julius Hann, former director and editor of the *Meteorologisches Zeitschrift*, had his room at the Institute. Among Schmidt's colleagues in the Institute were Exner, Defant, Wagner, R. Schneider, Hanzlik and von Ficker—a notable company.

Schmidt's main interest at that time, as indeed in later years, lay in the study of the structure of the atmosphere. It was a time when the first fruits of the international investigation of the upper air were being gathered. He was anxious to test their basis and invited me to collaborate with him in finding the lag of the instruments which were being used. The result proved to our satisfaction that the stratosphere could not be explained away as due to lag in the instruments.

Shortly afterwards, Schmidt turned his attention to an examination of barometric waves of relatively short period, particularly in the neighbourhood of Innsbruck. He found that the waves agreed with the waves which would be expected at the boundary between two currents of different density and that observations of cloud confirmed his deductions. He gave an account of his experiments at the Sheffield meeting of the British Association in 1910.

During and after the Great War, Schmidt became specially interested in the phenomena of turbulence and worked on this subject at about the same time as G. I. Taylor was working on it in Great Britain. The results of his work he embodied later in a book entitled: "Der Massenaustausch in freier Luft und verwandte Erscheinungen". Schmidt attacked the problem of turbulence in a slightly different way from that adopted by Taylor. His development of the theory was based on the assumption that an eddy carried with it (at least throughout the period of life in which it is of interest) the momentum with which it enters the field of observation. The quantity which he defined as *Austausch* is equal to the eddy viscosity multiplied by the density. The lead which Schmidt gave has been followed by other writers such as Prandtl and von Kármán.

In this as in other branches of meteorology, Schmidt always wanted to get behind the formulæ and the mathematics to the underlying physical principles. This is illustrated by a remark of L. F. Richardson's about the independence of the coefficient of eddy diffusion of the quantity diffused: "This was explained by G. I. Taylor and later W. Schmidt gave the general notion behind any mathematical argument in the form that an exchange of mass goes on, and that the measure c will be the same for any properties which this mass simply carries with it."

In 1930 Schmidt was appointed editor of the *Meteorologische Zeitschrift* in collaboration with Süring, and under his editorship the *Zeitschrift* maintained its high position as the leading monthly meteorological journal of the world.

In 1924 Schmidt was appointed professor of meteorology at the Agricultural College at Vienna, and he became particularly interested in problems of local climatology. During this period and the period while he was director of the Institute after the death of Exner in 1930, he gave himself wholeheartedly to investigations in this subject. It was at a time when funds for scientific research were very difficult to secure in Vienna, but he managed to get some help from the Deutsche Notgemeinschaft and he fitted out a travelling observatory for investigating the practically simultaneous variations in conditions in different parts of Vienna and the neighbourhood. Later on, he extended these investigations of local climate and micro-climatology to some parts of the Austrian Alps, and he gave a lecture before the Royal Meteorological Society in March 1934 briefly describing this work. In the following year he described the results of his investigations of turbulence and of the flow of air in the neighbourhood of the ground in a paper read before the Royal Aeronautical Society.

Early in 1935, after the death of Prof. Wallen, Schmidt took charge of the International Commission for Agricultural Meteorology, of which he had been secretary, and he was elected president at the meeting of the Commission in Danzig in 1935. At the end of 1935 he was awarded the Symons Gold Medal of the Royal Meteorological Society, perhaps the highest meteorological award of any in the world. His most recent work was a book written in collaboration with Dr. Brezina on "Kunstliche Klima in der Umgebung des Menschen", a copy of which he sent to me with a friendly note on November 25, only two days before he died.

Schmidt loved the country and the mountains as he loved his work and intercourse with his colleagues. He was a great meteorologist and a lovable man. His loss will be keenly felt by all who knew him personally and by many who knew him only through his published work. It is a blow which falls particularly severely on Vienna, the more so coming as it does after the sudden and unexpected death of Exner six years ago. E. GOLD.

Prof. J. T. Cash, F.R.S.

JOHN THEODORE CASH, emeritus professor of materia medica and therapeutics in the University of Aberdeen, who died on November 30, was a man of wide sympathies and, to those fortunate to know him intimately, a delightful companion. Born in Manchester in 1854, he studied arts and medicine at Edinburgh, qualified as M.B., C.M. in 1876, and proceeded to M.D., his thesis for which earned a gold medal, in 1879. After qualification he worked and studied at Paris, Vienna, Berlin and Leipzig.

Cash's early interests were in physiology and hygiene, but later they became almost purely pharmacological. The post-Continental period he spent in London, and investigated the pharmacological action of organic lead compounds, the action of chemical disinfectants (which he reported to the Local Government Board), and contributed, with Lauder Brunton, an important paper on the connexion between chemical constitution and physiological action to the Royal Society. He was elected a fellow of the Royal Society in 1887.

The appointment of Cash to the chair of materia medica and therapeutics at Aberdeen in 1886 was a surprise, for the chair had previously been held by medical practitioners, and Theodore Cash was a pure researcher. The appointment was, however, fully justified. Although only a part-time job, he devoted himself wholly to university work. A student of his first class was Arthur Cushny, who became successively professor of pharmacology in the University of Michigan, in University College, London, and lastly professor of materia medica and therapeutics in the University of Edinburgh.

At Aberdeen, Cash continued his investigations on chemical constitution and physiological action, then on the action of the pure organic nitrites prepared by Dunstan, and later on the action of the aconitines, which also had been prepared by Dunstan. The results were incorporated in papers to the Royal Society. They show that thoroughness and attention to detail which is characteristic of all Cash's work. He also investigated and wrote, among other matters, on tobacco smoking and skin irritants. His administrative work was equally thorough. For a time he was dean of the Faculty of Medicine and the University's representative on the General Medical Council. His work was acknowledged by the LL.D. of Edinburgh and, after retirement, of Aberdeen.

Cash was renowned as a fisherman as well as a pharmacologist. Once, the present writer when at a fisherman's inn in Scotland inquired from a visitor what fly he used and he replied "Cash's". On relating the incident to Prof. Cash, he confessed to having prepared and tried his own flies. This incident illustrates the man; he was as modest of his prowess with the rod as of his abilities in other spheres. He fished nearly all the streams of the British Isles, and up to a few years ago could still be found occasionally on the banks of his beloved Don.

Prof. Cash married the youngest daughter of the Right Hon. John Bright. Her death, soon after their removal to Hereford, was a great blow to him. There are four children of the marriage, two sons and two daughters, to whom we extend our sympathy.
C. R. M.

Dr. G. Schack-Sommer

DR. GUSTAF SCHACK-SOMMER died in London on October 16, aged eighty-two years. The sugar industry, home-grown sugar in particular, and his many friends will regret the passing of one who was blessed with a charming personality and presence, and whose interest in sugar was maintained to the last. He was unmarried. It was his intention to be present at the International Conference of Sugar Analysts in London in September, but unfortunately he was prevented by ill-health at the last moment. His family home was at Marienlyst, Elsinore, in Denmark, but at the time of his birth in 1854 his father was Danish Consul in Hamburg, and it was there that he spent his school life, although the summer vacation was always spent at Elsinore. In 1872 he was attracted to Heidelberg by the work of Bunsen, Kirchhoff and Kopp, and in 1875 he graduated and obtained his Ph.D. degree. His first professional post was in a German chemical works.

In 1877 Dr. Schack-Sommer decided to live in England and took the opportunity offered him to assist at one of the first alkali works in this country, the Newcastle Chemical Works. In 1878 he left Newcastle for Liverpool, where he joined the sugar-refining firm of Crosfield, Barrow and Co., of which he became a partner in 1884. In the same year he renounced his Danish nationality in favour of English. In 1881 he assisted in the foundation of the Society of Chemical Industry; he became a fellow of the Institute of Chemistry a few years later.

Dr. Schack-Sommer's early years in Germany had impressed upon him the benefits resulting from the growing of sugar beets, and from 1889 until 1895 he was instrumental in the growing of sugar beet in Lancashire and Ireland. Each year the results were carefully tabulated, supporting his contention that the crop was as suitable for England as for the Continent. With other pioneers, of whom Lord Denbigh and Sir George Courthorpe were the chief, he never missed an opportunity either at lectures or meetings of impressing all concerned with the merits of beet growing in this country. In 1890 he delivered a lecture which was attended by many members of Parliament interested in agriculture, and he was one of the earliest members of the British Sugar Beet Council, becoming chairman of the Liverpool section in 1895. He frequently recalled the pleasure it had given him to be present at the invitation of Sir George Courthorpe when the first batch of white sugar ever produced from English grown beets was completed at Cantley in 1912. Earlier attempts in 1868 at Lavenham had only produced syrups.

In 1894 the refinery of David Martineau and Sons, one of the oldest established in the sugar industry, was burnt to the ground, and in the following year Dr. Schack-Sommer assisted members of the old company to carry on its tradition by the formation of a new company. Of this company, now known as Martineaus, Ltd., he became the first chairman, a position which he held for thirty years, until advancing years prompted him to retire at the age of seventy-two. His tact and ability during these years are gratefully remembered, and even in his retirement he was a frequent visitor to the place of his former labours up to within a fortnight of his death.

Mr. Hugh Richardson

We regret to learn that Mr. Hugh Richardson, who for many years had a stimulating influence upon school science teaching, died on November 24 at seventy-two years of age. Mr. Richardson was educated at Bootham School, York, and King's College, Cambridge, where he graduated in 1887. In the following year he became a master on the modern side of Sedbergh School, Yorks, where he remained until 1897, when he became science master at Bootham School, remaining in that position until he retired in 1914. He was an enthusiastic teacher with unusually wide interests and fertility of ideas; and his work at Bootham School represented science teaching at its best, being both practical and comprehensive. The school possesses an astronomical observatory, and Mr. Richardson used this to teach astronomy by similar practical methods to those adopted by him for instruction in physics and chemistry, botany and geography. He was an examiner in botany for matriculation at the University of London in 1904–7, and was secretary of the Educational Science Section of the British Association during the years 1906–15.

When attention was being given to the application of scientific methods in the teaching of geography, Mr. Richardson, with the late Mr. A. T. Simmons, produced in 1905 the first helpful guide for use in schools, in their "Introduction to Practical Geography". He was also the editor from 1911 until 1919 of a Nature Study Series published by the Cambridge University Press.

During the last twenty years Mr. Richardson has led the life of an enlightened country landlord in Northumberland, planting trees, studying butterflies and their natural history relationships and raising varieties of primulas and gentians. He maintained to the last a keen interest in all developments of science and their relation to human life and will be remembered with affection and esteem by all who came in contact with him in educational and scientific circles.

We regret to announce the following deaths:

Sir John Bland-Sutton, Bt., president of the Royal College of Surgeons in 1923–26, on December 20, aged eighty-one years.

Prof. F. A. Laws, emeritus professor of electrical measurements in the Massachusetts Institute of Technology, on November 12, aged sixty-nine years.

Prof. R. F. C. Leith, emeritus professor of pathology and bacteriology in the University of Birmingham, on December 14, aged eighty-two years.

Sir John Robertson, C.M.G., O.B.E., professor of hygiene and public health in the University of Birmingham, on December 16, aged seventy-four years.

Prof. H. Westergaard, formerly professor of statistics in the University of Copenhagen, known for his statistical work in connexion with population and other social problems, on December 13, aged eighty-four years.

News and Views

Twelve Notable American Inventions

The granting of patents in the United States was provided for in the Constitution, and on April 10, 1790, Congress specified how patents were to be issued. It was, however, not until an act of July 4, 1836, that the Patent Office was established under a Commissioner. In that year, too, the Patent Office started numbering serially the patents issued. In connexion with the centenary of these events, a list of twelve of the inventions that have done most to change life in America, together with the inventors' names, has been drawn up. The list is as follows: The telephone, Alexander Graham Bell (1847–1922); the electric telegraph, Samuel Finley Breese Morse (1791–1872); the electric light, the cinema and the gramophone, Thomas Alva Edison (1847–1931); the commercial steamboat, Robert Fulton (1765–1815); the aeroplane, Wilbur Wright (1867–1912); the air-brake for trains, George Westinghouse (1846–1916); the linotype machine, Ottomar Merganthaler (1854–99); the sewing machine, Elias Howe (1819–67); the cotton gin, Eli Whitney (1765–1825); the vulcanization of rubber, Charles Goodyear (1800–60); a practical reaping machine, Cyrus McCormick (1809–84); and aluminium manufacture, Charles Martin Hall (1863–1914). The compilation of any such list is always a matter of great difficulty, but there can be no question that the inventors and inventions here recalled are truly representative of the great contributions to mechanical progress by men of American nationality.

Coulomb and Structural Engineering

To mark the bicentenary of the birth of Charles Augustin Coulomb (1736–1806), to which reference was made in NATURE of June 13, p. 976, Mr. S. B. Hamilton read to the Newcomen Society on December 16 a paper dealing with his work as a "Pioneer in the Science of Construction". After briefly sketching Coulomb's career, Mr. Hamilton dealt first with Coulomb's paper written in 1773 entitled "Essay on the Application of the Rules of Maxima and Minima to Statical Problems Relating to Architecture". This paper, which has never been published in English, was concerned with beams, piers and arches. Mr. Hamilton then turned to the researches of Coulomb on torsion, and after reviewing the work of Galileo, Mariotte, Hooke, La Hire and many others, he said that Coulomb, in considering the strength of materials, realized that brittle materials subject to crushing failed by shear; that he recognized the truth of Hooke's law and gave it its true place in elastic theory; that his theories of bending and twisting, although incomplete, were a sound contribution to knowledge, and still provide the basis of everyday calculations; that by a stroke of genius he anticipated the modern view that elastic strains are due to distortion of the space lattice within a crystal, while plastic deformation and fracture are due to the development of slip planes; and he also derived a satisfactory *simple* method of calculating the thrust of earth against retaining walls, and made a sound contribution to the study of masonry arches.

Air Raid Precautions

THE sixth of the handbooks issued by the Air Raid Precautions Department of the Home Office is entitled "Air Raid Precautions in Factories and Business Premises" (London : H.M. Stationery Office, 1936. 6*d*. net), and is intended primarily for factory occupiers, for occupiers of large commercial premises and other employers of labour, on whom would rest in time of emergency a responsibility for the protection of their employees while at work and the safeguarding of their property. The handbook explains that the air raid precautionary services which are being organized by local authorities all over the country should be supplemented by the individual efforts of householders and of employers of labour. It is suggested that in undertakings employing considerable numbers of workers, a scheme of air raid precautions embracing as many as possible of the services required should be worked out. The importance of close co-operation with the local authority of the area is stressed. Since in the event of air attack it would be impossible to improvise the necessary precautionary measures at short notice, the measures to be adopted should be surveyed at the present time and the necessary plans and preliminary arrangements made for putting them into force without delay. The handbook contains detailed guidance on means of protecting employees against gas, and blast and splinters from high-explosive bombs; the safeguarding of property and material from damage, and arrangements for emergency repair work; first-aid facilities; the organization of adequate fire-fighting appliances, including special measures to deal with incendiary bombs; decontamination of material affected by persistent gas; provision of emergency communications and steps to ensure the effectiveness of lighting restrictions. Employers of labour are recommended to prepare schemes covering these aspects of air raid precautions and to arrange for their employees to receive training in the duties involved.

Celtic Studies

MR. J. M. DE NAVARRO, in his John Rhŷs Memorial Lecture for 1936, delivered before the British Academy on December 17, surveyed the history of research in an early phase of Celtic culture, dealing with the La Tène period of the European Iron Age, in which the Celtic peoples emerged from the half light preceding the dawn of written history. He pointed out that the geographical extension of the La Tène civilization and its association with Celtic peoples was first determined by Sir Augustus Franks. Subsequent research has tended to confirm his views. No serious contribution to the study of this civilization was made before the fifties and sixties of the last century, when Thurnham, Franks and the German archæologist Lindenschmidt made research possible by assembling various La Tène types into a definite group. The problem was at first approached in the light of literary evidence. Therefore, Mr. de Navarro went on to show, special importance is attached to the typological work in 1885 of Tischler, which resulted in his division of the La Tène period into three phases, and the work five years later of Sir Arthur Evans on the Aylesford urnfield, a contribution of which the significance is felt more to-day than it was then. After reference to Reinecke, Déchelette and others, special mention was made in dealing with post-War activities in this field to the work of Jacobsthal, who like Reinecke was a trained classical archæologist. He viewed the La Tène style on its own merits, and not as a mere barbaric reflection of classical art. Finally, in discussing the locality in which the La Tène civilization originated, M. de Navarro expressed himself as in agreement with Déchelette and Dr. R. M. Wheeler in placing it in the region of the rich Early La Tène chieftains' graves of the middle Rhenish area.

Central American Studies: The Copan Project

DR. A. V. KIDDER, reporting on the work of the Division of Historical Research of the Carnegie Institution, Washington, D.C. (Year Book, Carnegie Institution of Washington, 1935), in Central America during the year 1935, records two additions to the already wide range of subjects embraced in the Institution's scheme of correlated research in the archæology, ethnography, physical anthropology and human ecology of Yucatan and Honduras. The new activities are the Copan Project and the Maize Survey. The Copan Project is a joint undertaking with the Government of Honduras to conserve and make available for scientific study and lay observation outstanding examples of the architectural and sculptural art of the ancient Maya. Similar work has already been carried out by the Institution on the temples of Chichen Itza and the stelæ of Quirigua. Copan is a centre in which are the finest products of the art of the Old Empire of the ancient Maya. It has the added interest that not only was it one of the first sites investigated by those pioneers of Central American archæology, Stevens and Catherwood, in the earlier half of the nineteenth century, but it was also the site from which A. P. Maudslay obtained, at his own expense and with immense difficulty and labour, his famous collection of plaster casts of architectural and artistic detail, of which examples are now displayed in the British Museum, after many years of neglect. The operations of the Institution at Copan began in 1935 under Mr. Gustav Stromwik, and have already produced important chronological data relating to pottery found at the base of reconditioned stelae.

The Maize Survey

THE Maize Survey has been established by the Institution in co-operation with the United States Department of Agriculture, officers from the Department being seconded for the purpose. The object of the survey is to investigate the origin of maize and to make a study of the maize agronomy of the Maya area. Although maize is the cereal which made possible the rise of pre-Columbian American civilization, its ancestry is problematical and it is not known certainly where and when it was brought under cultivation—a question having an intimate bearing on the beginnings of higher New World culture, including that of the Maya. In reporting on the results of a preliminary survey, which lasted for about a month in the field, Messrs. R. A. Emerson and J. K. Kempton offer certain tentative conclusions, which will serve to throw some light on the density of the ancient population and the relative proportions of the urban and agricultural population. The cultivation of maize, as at present practised, is on the milpa system; that is, a plot, after being burned off, is cultivated for two years, when it is allowed to revert to forest conditions, taking about eight to ten years to become completely re-established and ready for burning off again. Consumption is at an average rate of 1·6 lb. per head per day, which gives an annual consumption by a family of two adults and three children requiring from three to four acres under cultivation. This is about the amount which the Indians now claim to cultivate. The milpa system is the only system possible in Yucatan, even with modern tools and transport, and may, therefore, be presumed to be that followed by the ancient Maya. There is no evidence that it might not be followed indefinitely. The region, as thus cultivated, is capable of supporting a population of fifty persons per square mile, with ten persons as non-agricultural urban inhabitants. Maize cultivation has now completely supplanted the cotton grown by the ancient Maya, and only a small quantity of tobacco is grown.

New Exhibits in the Museums at Kew

THROUGH the generosity of various firms, the Royal Botanic Gardens, Kew, have recently acquired some additional specimens of general interest to the public. A new set of examples in Museum IV showing the various processes in the manufacture of a modern tennis racket has been presented by Messrs. F. H. Ayres, Ltd. The old method of making a tennis racket was to bend a single strip of ash into the required shape, but now a better process has been developed by the use of laminated wood of various kinds. In the modern examples on exhibit, the outer layer is of English oak, the innermost is of ash, and the several ply between are of Canadian birch and English beech with an insertion of walnut. The wedge at the top of the handle is of English sycamore, the top and side clasps are of Malayan lauan, whilst the wedge bend is of Canadian rock elm. A very carefully prepared series of veneers is shown in Museum No. III. The samples shown have been presented by Messrs. John Wright and Sons (Veneers), Ltd., Avon Wharf, Mile End Road, E.3, many of them having been supplied by the firm for the interior decoration of the *Queen Mary*. The veneers are cut from logs obtained from many parts of the world, some of the species being rare and not even yet known botanically. By very thin cutting in various directions a single tree supplies a great quantity and range of veneers, and very large sheets are obtained by cutting around the tree with a rotary machine. In the same Museum (No. III) new exhibits include a fine series of photographs by Dr. I. B. Pole-Evans, which give a good idea of the floral regions of South Africa, and alongside are bouquets of some of the beautiful everlasting flowers (mostly Composites) from the same region. These have been sent by Dr. Fourcade, Humansdorp, and Dr. Muir, Riversdale. In the large Indian case at the west end of the building are displayed a series of botanical paintings of Swiss alpine plants by the late Miss Sidney E. Forster and presented by Miss A. E. Pepys in 1934, together with a fine set of coloured postcards of similar subjects from the private collection of the Director.

'Degassing' by Electricity

IN *World Power* of October an interesting device is described for 'degassing' underground channels, such as sewers, drains and conduits, which has been used successfully abroad. Many large towns have records of street explosions proving the dangers arising from fortuitous concentration of gases such as methane, ether and benzene arising from the greater use of petrols in vehicles and the increasing variety of industrial chemical processes. As a rule, these gases are heavier than air, and become highly explosive when mixed with it. The apparatus consists of a motor-driven centrifugal suction fan. This is connected by suitable tubing to a floating suction head. The heavy gases are collected as nearly as possible at the level of the water at the suction head and pass through the tube with considerable velocity to the fan in the container. The power taken to drive the fan is only nine hundredths of a horsepower, and its capacity is a third of a cubic metre per second. The electrical vehicle used for transporting the degasser is operated by an 80-volt battery. According to recent experiments, an area contained by a circumference of about 300 metres and covering sewers approximately 1,000 metres in total length can be degassed in 10–15 minutes. It was proved that the ordinary method of circulating fresh air in the system was useless and sometimes dangerous.

Effects produced by Ultra-Sonic Vibrations

AN abstract of a paper read by Dr. L. A. Chambers of the School of Medicine of the University of Pennsylvania to the Institute of Radio Engineers, on the effects produced by intense sounds on liquids, has been issued by Science Service, of Washington, D.C. The intense sounds produce impacts on the liquids comparable to mechanical blows and make changes in them which will sometimes be useful in science and industry and should prove most useful in the field of medicine. Dr. Chambers uses sound vibrations having a frequency of 1,200 cycles per second and an intensity which is at least equal to one hundred times that of a large orchestra when playing together. These vibrations are produced by electric oscillators and kindred devices. When milk has been subjected to these vibrations, it acts as if it were purely homogeneous. The cream cannot be made to separate from it, and it is stated that it is now more digestible. Rapid progress is being made in the field of medical research, and it has been shown that certain organisms are killed by the pressure pulses. Dr. Chambers' researches have shown that these intense mechanical vibrations will be most useful for the preparation of serums. Whisky subjected to this treatment aged very rapidly. Samples subjected to it for seven hours produced a whisky which experts stated to be equivalent to one which had been aged in the wood for four years in the usual way.

Forests in the Canadian Prairie Provinces

A FOREST SERVICE BULLETIN, No. 88, has been issued under the auspices of the Department of the Interior, Canada (Ottawa, Printer to H.M. the King, 1936) entitled "Forest and Forest Industries of the Prairie Provinces" by J. D. B. Harrison of the Division of Forest Economics. The Prairie Provinces occupy a part of the interior continental plain of North America and have thus many characteristics which differentiate them from other parts of the Dominion. A National Forest Inventory was commenced jointly in 1929 by the Dominion and provincial forest authorities but had to be retarded owing to the general economic situation; in spite of this it has proved possible to collect a large amount of information on the subject of these Prairie Provinces and this the author summarizes in the present bulletin. A brief but comprehensive review of the principal factors affecting the forests, together with a description of the forests themselves, is given. The dominance of agriculture as the principal industry of the region is emphasized, and questions of population and of communications dealt with, in order to place the forest resources in their proper economic perspective. Sufficient historical material is included, in the appropriate chapters, to explain the course of events leading up to the present situation. The bulletin is written by an economic research officer from the purely economic point of view. It is, however, none the less disquieting to observe that the forests of a country are still mainly regarded from the point of view of what they can be made to yield in produce to man, whilst the protection they offer to mankind as a whole, and to certain of the natural resources of the country, are so little appreciated until almost irretrievable damage by over-exploitation has been done.

Agricultural Statistics

THE International Institute of Agriculture, Rome, has now published the sixth of its economic commentaries, "The World Agricultural Situation in 1934–5" (price 25 lire). As in the preceding issue, the volume is divided into two parts, the first of which deals with world agriculture and the second with the individual policy and conditions in the different countries. Both sections contain a wealth of interesting material of which it is impossible to give more than the briefest outline. Under the first heading, an analysis is made of the more important changes and trends in world economy as influenced by national planning, together with a survey of the market conditions of the principal agricultural crops and livestock. The year under review was a period of adjustments and adaptations involved in the carrying out of schemes of planning and control rather than a period of new initiations in economic organization, the outstanding feature being the increasing development of economic autarchy, which in theory stands almost universally condemned. The effects of this tendency, economic, political and technical, are discussed at length, and it is shown that greater stability is now being sought by the formation of large economic combinations between countries usually with close political associations. Further, the various forms of industrialization that are taking place in the so-called agricultural countries are shown to be producing far-reaching repercussions upon international economic relations. The information in the second part is principally concerned with Government measures for farm relief and the economic conditions of agriculture prevailing in the various countries. More than thirty countries are considered, information with regard to Austria, Portugal and Portuguese Colonies being included in this issue for the first time. Data for Argentina and Poland which were omitted in the last issue of the commentary are again included.

Medical Centre for Moscow

A LARGE medical centre which will include the All-Union Institute of Experimental Medicine, the institutes of the State Health Department, the Second Moscow Medical University and a traumatological institute, will be built on the outskirts of Moscow between Pokrovskoye-Streshnievo and Khoroshevsky Serebrianny Bor in 1937. Among the buildings already under construction on the site are the Epidemiological and Microbiological Institutes of the State Health Inspection Department, veterinary stations for horses, laboratories where horse serums and vaccines will be prepared and a department to house small animals for experimental purposes. The Traumatological Institute will have a children's clinic for the study of common injuries, especially those sustained in street accidents. An Orthopædic Department, a special jaw clinic, and a large department for mechanical therapy are also included in the plans for this Institute. The buildings of the All-Union Institute of Experimental Medicine will be commenced next spring and will occupy a site of 1,000 acres. The Institute will also serve as a post-graduate medical school.

Gold Coast Surveys

THE report of the Gold Coast Survey for 1935–36 (Accra, 1936. 1*s.*), while recording a steady development of useful work, lays stress on the want of resources for the adequate survey of the Colony. It is the difficulty which most colonial surveys have to face and represents the results of a short-sighted policy. The greater part of the Northern Territories is completely unmapped. In the south and in Ashanti only part of the primary triangulation is completed. Development of prospective mining areas is liable to be checked by want of geological surveys, which cannot be carried out without a topographical map. Air surveys have been considered, but the two difficulties are much densely forested country and a lack of fixed points from which to work. Another urgent matter is the extension of geodetic levelling. An old network of levels exists, but requires checking with modern standards of accuracy.

Steam Locomotives and Small Craft

FROM the Association of Engineering and Shipbuilding Draughtsmen come two pamphlets—"Steam Locomotive Design" by D. Patrick (London: The Draughtsman Publishing Co., Ltd. 4*s.*) and "Small Craft Types" by John A. Mavor (*ibid.* 3*s.*). The former discusses the design of component parts and includes all the more important details, except the boiler and its attachments. An earlier publication dealt with preliminary design, and the present work carries it on from the point at which wheel arrangements, cylinder sizes, etc., have been determined, and, with the above exception, practically completes the subject in relation to engines of normal design. In his pamphlet, Mr. Mavor gives general descriptions and data of the humbler types of craft including trawlers, tugs, lightships, dredgers, etc., and explains the special features and working conditions peculiar to each. The main outlines of their design are presented, and the methods are indicated by which the forms of structure, machinery and fittings are adapted to meet the different conditions under which these ships are navigated and operated.

Catalogue of Fishes

GÜNTHER'S "Catalogue of Fishes in the British Museum" was issued in 1859–70, and has long been out of print. The great work of Cuvier and Valenciennes was never finished, and Günther's is the only complete systematic monograph of the group in existence, and is therefore indispensable to ichthyologists. The time that has elapsed since Günther prepared his catalogue has seen the collection on which it was based quadrupled, and the number of known species about doubled; these factors alone would make the preparation of a revised edition a heavy task, and if to them be added the necessary study of the numerous systematic monographs and faunistic memoirs that have appeared since the catalogue was published, it is clearly one that no man could hope to complete In these circumstances, to meet an evident demand, the Trustees of the British Museum have decided to reissue the "Catalogue of Fishes" in its original form, and at the original price of £3 9*s.* for the complete work in eight volumes. It will be available early in 1937.

Pathology and Bacteriology at Leeds

THE annual report of the Department of Pathology and Bacteriology of the University of Leeds, recently issued, by Profs. M. J. Stewart and J. W. McLeod, gives an account of the teaching and research work and routine examinations conducted in the Department during 1935. The research work includes the systematic investigation of industrial pulmonary affections, studies on new growths, and an investigation of types of the diphtheria bacillus present in six thousand cases of diphtheria occurring in England, Scotland, Ireland and Germany. Prof. R. D. Passey contributes a summary of researches carried out in the Department of Experimental Pathology and Cancer Research.

The Indian Earthworm

TEN years after its first appearance, Prof. K. N. Bahl's monograph on *Pheretima*, the Indian earthworm, has passed into a second edition (Lucknow: Lucknow Publishing House, 1936). That is sufficient to indicate that the work has found its place as a guide to teachers and students of Indian zoology, as one of the excellent series of Zoological Memoirs on Indian Animal Types, projected and edited by Prof. Bahl. The first edition was favourably reviewed in NATURE (119, 557; 1927), and the second is even better in that the author has revised the text and incorporated new information and illustrations.

Birds of Agricultural Importance

THE Ministry of Agriculture and Fisheries has issued, bound in an attractive folder, a group of twenty-three "Advisory Leaflets", dealing with the agricultural activities of common British birds. Several of these have already been referred to in NATURE. The price is 1*s.* 6*d.* net.

The Night Sky in January

IN the middle of the month at 22^h, the full pageantry of the winter constellations is on the meridian; the segment of bright stars is outlined by Capella (near the zenith), the Pleiades and Aldebaran, Rigel, Sirius, Procyon, Castor and Pollux, and so back to Capella. South of Orion's belt may be seen with the naked eye the hazy patch that marks the great gaseous nebula. The planet, Venus, is a brilliant object in the early evening sky; it will continue to increase in brightness until the middle of March. Venus is in conjunction with the moon on January 16^d 15^h and with Saturn on January 24^d 2^h after the two planets have set, their closest approach in the sky being 1·9°. Mars is a morning star as well as Jupiter, the latter rising only about one hour before the sun in mid-January. The phases of the Moon are: Last Quarter, January 4^d 14^h: New Moon, January 12^d 17^h: First Quarter, January 19^d 20^h: Full Moon, January 26^d 17^h. The only bright star to be seen occulted from Greenwich is τ Tauri (mag. 4·3) whose disappearance takes place on January 22^d at 18^h 0·6^m. Members of the Quadrantid meteor shower may be looked for about January 2–3, the radiant point being at R.A. 15^h 20^m and Dec. 53° N. The times of minima of Algol accessible to observation are: January 10^d 4^h, 13^d 1^h, 15^d 21^h, 18^d 18^h, 30^d 5^h.

Announcements

SIR ARTHUR HILL, Director of the Royal Botanic Gardens, Kew, has been awarded a Veitch Memorial Gold Medal of the Royal Horticultural Society for his services to horticulture.

THE American Association for the Advancement of Science will hold its ninety-ninth meeting in Atlantic City on December 28–January 2. The address of Dr. Karl T. Compton, the retiring president, will be entitled "The Electron: its Intellectual and Social Significance". The president-elect is Dr. Edwin G. Conklin. A new feature of this forthcoming meeting is an attempt to bring together for general programmes all those attending the meeting. January 1 has therefore been set aside as "Association Day". On this day, an Association luncheon will be held at which all members may participate; a general lecture on changes in the conception of cancer will be given by Dr. Walter Schiller of Vienna; and in the evening there will be an exhibition of scientific films. The Association will adjourn its sessions to Philadelphia on January 2.

THE well-known publishing firm of Ferdinand Enke in Stuttgart celebrates on January 1, 1937, the hundredth anniversary of its foundation. This firm specializes in works on medicine, natural science and law, and has published a number of important works and periodicals on these subjects.

DR. PAUL RAMDOHR, professor of mineralogy at Berlin, has been elected a member of the Geologiska Foreningen of Stockholm.

PROF. RICHARD KOLKWITZ, professor of botany in Berlin, has been elected an honorary member of the Botanical Society of Japan in Tokyo.

THE first award of two thousand dollars of the Squibb fellowship at Harvard University for research in organic chemistry by E. R. Squibb and Sons, New York, has been made to William P. Campbell of Hagerston, Md., for research in phenanthrene.

THE Institute of Malariology at Rome, directed by Prof. G. Bastianelli, has sent a mission to Abyssinia to study various aspects of malaria. The chief members of the mission are Prof. G. Lega (pathology and clinical medicine) and Prof. G. Raffaele (entomology, epidemiology and prophylaxis).

A STUDENTSHIP is offered to a young, recently qualified medical graduate who wishes to acquire experience in cancer research from the biological point of view and particularly from the virus aspect. The studentship is tenable at the Lister Institute for three years. Further information can be obtained from the secretary, British Empire Cancer Campaign, 12 Grosvenor Road, S.W.1.

H.M. STATIONERY OFFICE is now acting as an agent for the sale of publications of the British Museum. New publications of the Museum will, in future, be regularly listed in "Government Publications", the monthly catalogue of the Office.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:

Evening lecturer in electrical machinery and design in the West Ham Municipal College—Romford Road, Stratford—The Principal (December 31).

Assistant curator in charge of the Decorative Department in the Royal Botanic Gardens, Kew—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (January 4).

Lecturer in heat engines in the Wimbledon Technical College, Gladstone Road, S.W.19—The Principal (January 5).

Assistant lecturer in dairying in University College of Wales, Aberystwyth—The Registrar (January 11).

Lecturer in education and psychology in Rhodes University College, Grahamstown—The Secretary, Office of the High Commissioner for South Africa, Trafalgar Square, London, W.C.2 (January 18).

Botanist, advisory officer (Botanical Division), advisory officer (Soils and Chemistry Divisions), and junior assistant (Experiment Station) in the Rubber Research Institute of Malaya—The Secretary, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, London, S.W.7 (January 31).

University professor of pathology in the British Postgraduate Medical School—The Academic Registrar, University of London, W.C.1 (April 16).

Head of the Department of Dairy Chemistry in the National Institute for Research in Dairying, Shinfield, Nr. Reading—The Secretary.

Letters to the Editor

The Editor does not hold himself responsible for opinions expressed by his correspondents. He cannot undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*

NOTES ON POINTS IN SOME OF THIS WEEK'S LETTERS APPEAR ON P. 1102.

CORRESPONDENTS ARE INVITED TO ATTACH SIMILAR SUMMARIES TO THEIR COMMUNICATIONS.

Isotopic Weights by the Doublet Method

CONTINUING work with my second-order focusing mass-spectrograph, the doublet 31 formed by P and CF has been measured by the use of a mixture of phosphine, carbon tetrafluoride and helium in the discharge. On some of the plates obtained well-matched doublets appeared at 28 due to Si and CO derived from the walls of the tube. This was very fortunate, for the intensities of these lines are virtually beyond any ordinary control. The value of the packing fraction of ^{28}Si deduced is only slightly different from that already given.

The first determination of the packing fraction of an isotope of sulphur has been made by means of the doublet ^{32}S and O_2 obtained by means of a mixture of sulphur dioxide, oxygen and helium.

Measurement of the chlorine isotopes was first attempted with heavy phosphine PD_3 mixed with a little CCl_4. This behaved very badly in the discharge tube, and a much better result was later obtained by the use of propane and methyl chloride which, when suitably mixed, gave three doublets 36 due to H^{35}Cl and C_3, 37 due to ^{37}Cl and C_3H and 38 due to H^{37}Cl and C_3H_2. The masses of the chlorine isotopes were calculated from the first two and the result for ^{37}Cl confirmed by measurements of the third. The following are the results :

Doublet	Number of doublets measured	Difference in packing fraction	Difference of mass
^{28}Si, CO	11	6·15 ± 0·2	0 0172
^{31}P, CF	18	7 88 ± 0·15	0·0244
^{32}S. O_2	18	5·53 ± 0·1	0·0177
H^{35}Cl, C_3	8	6·25 ± 0·2	0·0225
^{37}Cl, C_3H	22	11·14 ± 0·2	0·0412

Symbol	Packing fraction	Isotopic weight
^{28}Si	−4·90	27·9863 ± 0·0007
^{31}P	−5·30	30·9836 ± 0·0006
^{32}S	−5·53	31·9823 ± 0·0003
^{35}Cl	−5·71	34·9800 ± 0·0008
^{37}Cl	−6·10	36 9775 ± 0·0008

In calculating these, I have used the values of the doublets appearing in my two previous letters[1]; however, since these appeared, other workers' values have been published. K. T. Bainbridge and E. B. Jordan[2], using a double focusing mass-spectrograph of about the same dispersion and even greater resolving power than mine, give for the fundamental doublet O,CH_4 a difference of mass of 0·0369 ± 0·0002, whereas I obtained 0·03601 ± 0·00024. The discrepancy only amounts to 5 parts in 10^6 in the absolute mass, but it is well outside the probable error.

I have therefore repeated my measurements with special precautions. The electric deflecting plates were resurfaced, a new front slit was fitted and a different form of discharge tube used, but the mean value given by thirteen doublets was virtually the same as mine given above. No individual doublet in this group even reached the higher figure.

As a final check and to eliminate any possible difference between atomic and molecular lines, I decided to measure the doublet CO, C_2H_4, which will obviously measure the same difference of mass, though less accurately. To get matched pairs in this case has proved extremely difficult, but after long running with pure ethane, this has been done and measurements of ten doublets definitely support my value.

Bainbridge and Jordan do not state with what unit their dispersion coefficients were calibrated. I used the bromine lines to calibrate the instrument originally, and for these two particular doublets was able to check the figures to within a fraction of 1 per cent by the positions of the neighbouring lines CH_3, OH in one case, and C_2H_3, C_2H_5 in the other. The discrepancy therefore remains quite unexplained.

Selective Absorption of Neutrons in Silver

WE have measured the absorption in boron of the neutrons which excite γ-rays in silver. The arrangement used is shown in Fig. 1. The silver in the form of a hollow cylinder 4 mm. thick surrounding the counter was shielded from the effects of stray neutrons by layers of B_4C about 5 mm. thick. After being slowed down by the paraffin block and the thermal neutrons filtered out by a cadmium sheet 0·5 mm. thick, the neutrons passed through the B_4C absorber placed directly beneath the silver.

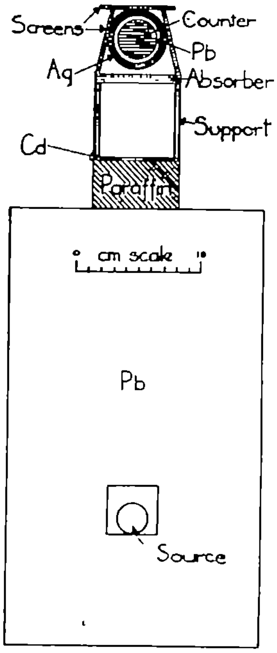

FIG. 1. Experimental arrangement.

Fig. 2 shows the curve obtained when the γ-ray activity induced in the silver is plotted against the amount of boron contained in the absorber. The figure shows also a second set of points obtained when the system consisting of the counter, silver, etc., was lowered 5 cm. The close similarity of the two curves shows that no appreciable correction for geometry is required.

The absorption curve of Fig. 2 may be analysed into two portions as is explained in the figure :

(i) An initial steep exponential decrease corresponding to an absorption coefficient of 8·1 gm.$^{-1}$ cm.^{2}.

(ii) A region of slow, almost linear decrease. Supposing this to be part of an exponential curve, the absorption coefficient is 0·24 gm.$^{-1}$ cm.^{2}. Most likely the curve is a combination of several exponentials. Extrapolating the second component to zero boron thickness, it is found that approximately one third of the total activity is due to component (i).

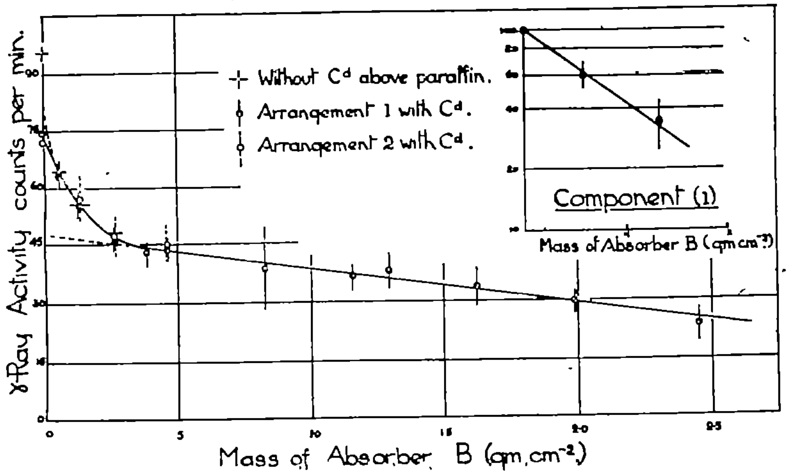

FIG. 2. γ-Ray activity for different boron thicknesses. Three sets of readings are plotted as explained in the text. Inset—Absorption curve for component (1) of the text.

The early part of the absorption curve was also determined without the cadmium filter. The points obtained are also shown in Fig. 2. It is seen to be almost identical with the previous curves except that the point for zero absorber lies about 25 per cent higher. This represents the amount of the γ-ray activity due to neutrons of thermal energy, and is of the same order of magnitude as the activity produced by that component having an absorption coefficient in boron of 8·1 gm.$^{-1}$ cm.^{2}.

On removal of the neutron source, the counter immediately registered its normal natural count, showing that the γ-rays do not arise from a decay process of appreciable period.

It is interesting to note the difference between the above curve and the curves obtained for the absorption of those neutrons which excite the 22 second and the 2·3 minute activities in silver. Both the latter curves can be analysed into an exponential part and an almost constant background representing about 15 per cent of the total activity (when samples of silver 0·5 mm. thick are used as detector). Measurements that have been made on the 22 second period indicate an absorption coefficient in boron (for the exponential portion) of 3·25 ± 0·15 gm.$^{-1}$ cm.^{2}. For the 2·3 minute period, much less accurate measurements indicate for the corresponding coefficient a value of about 1·5 gm.$^{-1}$ cm.^{2}.

Since there are only two known isotopes of silver, it is difficult to decide the origin of the two radioactivities and the γ-ray emission. A possible explanation of the above curves would be that a nucleus can possess two systems of energy levels, one corresponding to β-decay and the other to the emission of γ-radiation.

Assuming that:

(i) the $1/v$ law holds for boron absorption;

(ii) the thermal neutrons which are strongly absorbed in cadmium have energies of $\frac{3}{2}kT$ ($= 0·038$ volt if $T = 290°$ K.), and taking the value for the absorption coefficient in boron of thermal neutrons to be 28 gm.$^{-1}$ cm.^{2} as found by Goldsmith and Rasetti[1], the energy of the first resonance level for the neutrons which produce γ-rays in silver works out at 0·45 volt, whilst that corresponding to the harder component comes to about 500 volts. Since the second component probably consists, however, of the combination of a number of exponentials, the actual spacing of the first and second levels is probably a little smaller than this. Such a value is in good agreement with Bethe's[2] approximate calculations of the spacing of nuclear levels.

We are indebted to the Commonwealth Radium Laboratory for the supply of emanation with which this work was carried out, and particularly to Mr. W. N. Christiansen, who prepared the sources. We also wish to thank Prof. T. H. Laby for assistance in preparing this work for publication.

Activation of Silver by Neutrons

THE different authors who have dealt with the radioactivation of silver by neutrons agree in admitting the formation of two radio-elements such as would result from a process of neutron capture without emission of heavy particles. One would thus have in both cases

$$^{x}_{47}\mathrm{Ag} + ^{1}_{0}n = ^{x+1}_{47}\mathrm{Ag}.$$

The first radio-element would have a short period: 22 sec. (Amaldi and co-workers; Alichanow; Gaertner, *et al.*) or 26 sec. (Livingston, Henderson and Lawrence). The second one has a longer period 2·3 min. (Amaldi and others, Hevesy and Levi, *et al.*) or 154 sec. (Livingston and others). Bjerge and Westcott[1] alone have found a period of 40 sec., which is different from the generally admitted period.

Further, it seems surprising that the process of radioactivation mentioned above should be the only one observed with silver. Undoubtedly it is the most frequent for the elements beyond a certain atomic number. But would it not be possible to have

$$^{107}_{47}\mathrm{Ag} + ^{1}_{0}n = ^{104}_{45}\mathrm{Rh} + ^{4}_{2}\mathrm{He}\ ?$$

Now $^{104}_{45}$Rh radioactive with a period of 44 sec. is known and results from the irradiation of rhodium by neutrons. Is it not this radio-element that has been observed by Bjerge and Westcott?

In order to verify this conclusion, I have undertaken the following experiments:

(*a*) Irradiation of a silver sheet with the neutrons of a radium-beryllium source, the irradiation being continued for 0·5 min., 1 min., 2 min., followed by observation, with a Geiger-Muller counter, of the activity and of its variation with time; (b) irradiation of the same sheet for the same periods, but with 4 cm. paraffin interposed between the source and the silver.

For the interpretation of the results, we followed the method suggested by McLennan, Grimmet and Read[2]. Repeated experiments gave for the period in case (a) 47 ± 3 sec.; in case (b) 30 ± 4 sec. It seems thus that without paraffin, the swift neutrons form a radio-element different from those formed by slow neutrons. After irradiation for 15 min., one finds a curve which shows a period of 2·5 min. and another period which, in the case of interposition of paraffin, is about 30 sec. and reaches about 50 sec. when no paraffin is interposed.

It seems thus that the action of neutrons on silver determines the formation of three radio-elements: the first one is produced by the swift neutrons, period about 50 sec.; the second is produced only by the slow neutrons, period about 30 sec.; the third with a period of 2·5 min. is produced by the swift and by the slow neutrons, but with an intensity enhanced by interposing a hydrogenated substance between the source of neutrons and the silver.

A Simplified Procedure for Determining Normal Boiling Points by the Comparative Method*

ŚWIĘTOSŁAWSKI'S method[1] for determining the normal boiling point of a substance by comparing its boiling point with that of water at three or more pressures, and applying his equation involving the ratio of the *dt*/*dp* coefficients of the two liquids, can be simplified by working as nearly as possible at a pressure of one normal atmosphere. If the manostat, which equalizes the pressures in the two ebulliometers, can be adjusted previously to one normal atmosphere (as determined by the temperature of boiling of water in the barometric ebulliometer) the normal boiling point of the substance in the second ebulliometer can be measured directly.

If, as is likely to be the case, the pressure cannot be adjusted to one atmosphere within the required precision of ± 0·02 mm. of mercury, it is only necessary to make a second pair of observations at a pressure which differs so little from the first pressure that the variation of boiling point with respect to pressure can be assumed to be linear (over the small interval), both for water and for the substance under investigation. If the first pressure is below normal, the second preferably should be above normal, and vice versa. The normal boiling point can then be calculated from the observed boiling points by the use of simple proportion between the observed changes in boiling points and the correction to 760 mm. of mercury, corresponding to 100° as the defined normal boiling point of water. One form in which the equation may be written is

$$t_s = t_{s_1} + \frac{\Delta t_s}{\Delta t_w}(100 - t_{w_1}),$$

in which t_{s_1} and t_{w_1} represent either pair of observed boiling points of the substance and of water, respectively, and Δt_s, Δt_w are the changes in the boiling points occurring between the first and second pairs of observations.

Determination of the boiling point of carbon tetrachloride and of trimethylcarbinol.

Substance	Boiling point of water (°C.)	Boiling point of substance (°C.)	Normal boiling point of substance determined by Świętosławski's procedure (°C.)
Carbon tetrachloride	99 527	76·180	
	99·934	76·608	
	100 000	76·685 (calc.)	76 685
Trimethylcarbinol	99·885	82·240	
	99·980	82 327	
	100 000	82 345 (calc)	82·347

To illustrate the applicability of this simplified procedure, the normal boiling points of carbon tetrachloride and trimethylcarbinol were determined and compared with those obtained by Świętosławski's procedure, using the dt_s/dt_w ratio for reducing to normal pressure the boiling point actually measured. The carbon tetrachloride used for the measurements was of the fifth degree of purity on Świętosławski's scale[2], having a difference of 0·002° C. between the boiling point and temperature of condensation in a standard differential ebulliometer. The trimethylcarbinol was of the fourth degree of purity, having a corresponding difference of 0·007° C. The data are given in the accompanying table.

The agreement of the data obtained by the use of the two methods demonstrates the validity and high precision of the new method. Details will be published elsewhere.

Vibrations of the Ethylene Molecule

BONNER[1] has recently recorded seven frequencies (1619, 3009, 1341, 3069, 950, 2880 and 1654) in the Raman spectrum of liquid ethylene. In the earlier work of Dickinson, Dillon and Rassetti[2] on the Raman spectrum of ethylene gas, 1623·3, 3019·3, 1342·4, 3240, 3272 and 2880 were recorded. I have recently obtained an intense Raman spectrum of ethylene gas at a pressure of 40 atmospheres using λ4358 radiation, and have measured lines at 1626, 3020, 1343, 2880 and 1656. Thus, both Bonner and I have failed to record the lines at 3240 and 3272, and these are probably spurious.

Vibrations of the ethylene molecule and the deduction of the force constants therefrom have been the subject of recent investigations by several workers[1,3,4,5]. Six of the twelve fundamental frequencies of this molecule are active in the Raman effect, and these have been identified (see refs. 5

and 1) as 1621·3, 3019·0, 1343·9, 3069·0, 950·0 and 1100. Of these six, the last one has not yet been observed, but 3069·0 and 950·0 have been recorded by Bonner in the liquid. That they do not appear in the gas is presumably due to the very low intensity which may be expected of them. The first three, namely 1621·3, 3019·0 and 1343·9, need special mention, as they should be intense and exhibit a high degree of polarization in the Raman spectra.

I have made a careful study of the state of polarization of two of these three intense Raman lines. Details will be given elsewhere and only the results mentioned here. Depolarization factors of 0·10 and 0·17 respectively have been obtained for lines 3019·0 and 1343·9. The depolarization factor for 1621·3 could not be determined with as good an accuracy, but the results show it to be also of the same low order. Such low depolarization factors are in complete accord with the theory.

The fact that two weak lines at 2880 and 1656 which are not fundamentals have been recorded in the Raman spectrum both by Bonner and by me in the liquid and the gas respectively is interesting. As has been suggested by Bonner, 1656 may be regarded as the overtone of an inactive fundamental at 825, appearing as a result of its proximity to 1620 (similar instances occur in the Raman spectra of carbon dioxide, carbon disulphide, etc.), but the origin of 2880 is not at all clear.

Dissociation Energy of Carbon Monoxide and the Abundance of Elements in Stellar Atmospheres

A GREAT deal of work has been carried out by many investigators during the last two years in order to determine the heat of dissociation of carbon monoxide by means of spectroscopic methods. But as yet this very important figure is not known with any certainty, the values proposed by different authors varying between 11·06 and 6·9 e.v.; however, only the values 9·1 e.v. and less are not in contradiction with existing spectroscopic and thermochemical data.

The purpose of the present letter is to direct attention to the fact, that from all the proposed values for D(CO) equal or less than 9·1 e.v., only the value $D(\text{CO}) = 9{\cdot}1$ e.v. proposed by Goldfinger, Lasareff and Rosen[1] and by Herzberg[2] is in good agreement with our actual theoretical and observational knowledge of the composition of the atmospheres of late-type stars. A detailed investigation of this question has proved that: either the heat of dissociation of CO is really $D(\text{CO}) = 9{\cdot}1$ e.v., and the related value of the heat of dissociation of CN is $D(\text{CN}) = 5{\cdot}97$ e.v., or the abundances of light atoms in the main sequence as postulated by Cambresier and Rosenfeld[3] and by Russell[4] must be entirely revised.

Owing to the important role played by D(CO) in all the calculations of molecular abundances in the late-type stars, the astrophysical evidence for the proposed value of D(CO) seems worth mentioning. Details on the subject will be published elsewhere.

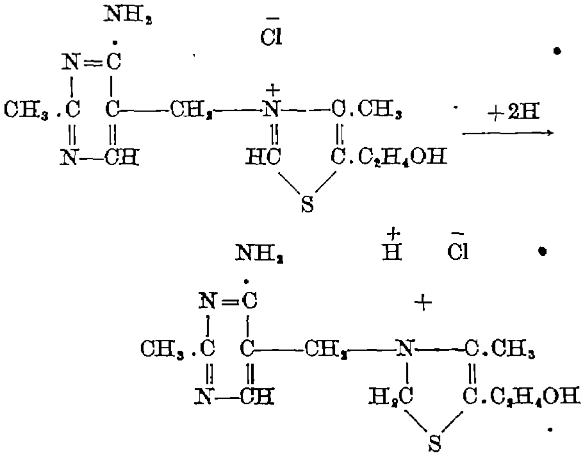
Hydrogenation of Vitamin B_1

WHEN treated with platinum-black or with hydrosulphite, vitamin B_1 is easily reduced. Crystalline preparations from Hoffmann–La Roche and from I. G. Farben were used. They gave identical results. Hydrogenation with platinum-black was measured in Warburg–Barcroft manometers. In phosphate solution at pH 7·5, 0·94 mol H_2 was absorbed per mol vitamin (average of three experiments).

To measure the reduction by hydrosulphite, the manometric method described by O. Warburg, Christian and Griese[1] has been used. With this method, in bicarbonate solution, the acid formation due to oxidation of hydrosulphite ($Na_2S_2O_4$) to acid sulphite is measured. One mol of acid is equivalent to one atom of hydrogen. But in many cases[2], in addition to that, acid is derived from the reduction process itself.

It has been found that 2·76 mols of acid are produced in the reaction between hydrosulphite and vitamin (average of four experiments). The reaction is finished after three hours at 25° C. No acid formation takes place when the vitamin is treated with sulphite at pH 7·8. This possibility had to be excluded on account of the reaction between $NaHSO_3$ and vitamin at pH5[3]. Then, of the 2·76 mols of acid, only two can be accounted for by oxidation of hydrosulphite, because only two atoms of hydrogen are added by platinum-black. The additional acid must be derived from the reduction process itself. Therefore it is assumed that the reduction takes place at the double bond closest to the quaternary nitrogen[3]. Then only one hydrogen is added; the other one is split into an electron and a hydrogen ion. The electron neutralizes the nitrogen and acid is formed. Tentatively the reduction of vitamin B_1 can be formulated as follows:



A very similar reaction takes place when the coferments of Warburg and of von Euler are reduced with hydrosulphite. According to Warburg and Christian[4] 2·8–2·9 mols of acid per mol coferment appear. Here, as Karrer and Warburg[5] have shown, two atoms of hydrogen reduce the double bond attached to a pyridylium nitrogen.

Reductions effected by hydrosulphate are similar to reductions effected by substrates in the cell[1]. The fact that vitamin B_1 is reduced by hydrosulphite makes it probable that in the cell[6,7] acting as a catalyst, the vitamin is reduced in the same way.

Reversible Oxidation and Reduction of Chlorophyll

IN experimenting with ethyl chlorophyllide, for specimens of which we wish to thank Prof. A. Stoll, of Basle, we observed the following reactions which illustrate a hitherto unknown property of chlorophyll.

(1) When, to a solution of ethyl chlorophyllide in methyl alcohol, a few drops of a solution of *ferric* chloride in the same solvent are added, the characteristic green colour instantaneously changes to a greenish yellow. An addition of a small quantity of *ferrous* chloride at once restores the original green colour. If ferrous chloride is added first, the subsequent addition of ferric chloride does not cause any change in colour at all.

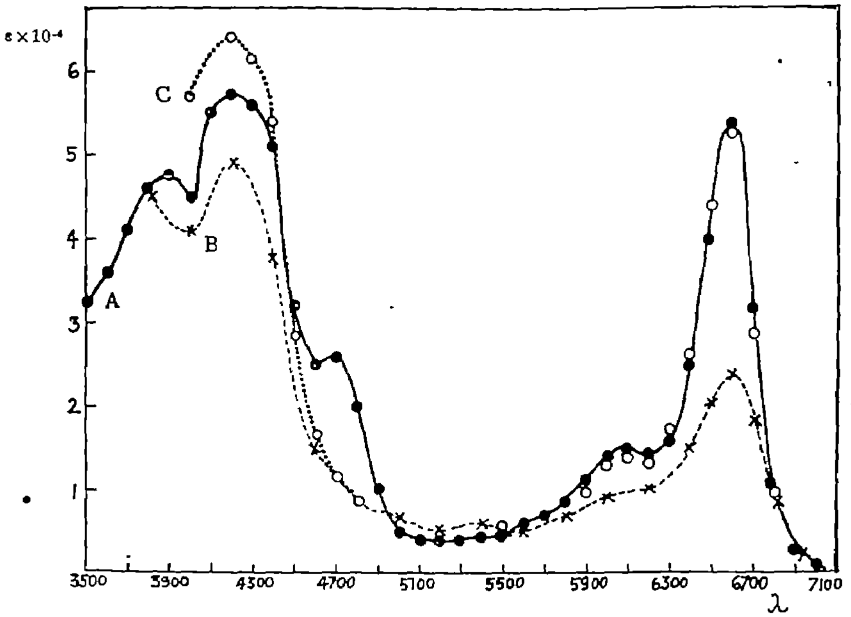

FIG. 1. Molecular extinction coefficient of ethyl chlorophyllide solutions · Curve *A*, original chlorophyllide; Curve *B*, oxidized chlorophyllide; Curve *C*, recovered chlorophyllide.

We measured, by means of a double monochromator and a photo-cell, the extinction curves of the original green solution, of the yellow (oxidized) solution, and of the recovered (reduced) green solution (Fig. 1). The oxidation causes a considerable weakening of the characteristic red band (5500–6900 A.), without affecting strongly the violet one. The extinction curve of the recovered green solution is practically identical with that of the original chlorophyllide, apart from a slight change in the violet consisting of the disappearance of the small hump at 4600 A., and a slight increase of absorption at shorter wavelengths, which we suspect to be due to a specific behaviour of the "C" component of chlorophyll.

It is thus highly probable that we have an equilibrium:

(I) Ethyl chlorophyllide + $Fe^{III} \rightleftarrows$ Oxidation product + Fe^{II}.

Another feature of the above reaction is the disappearance and reappearance of the fluorescence. The following figures show the intensity of the red fluorescence of the three solutions (excited by violet-blue light, which is absorbed by the yellow solution as well as by the green ones), measured by a photocell and galvanometer.

		Intensity of fluorescence (arbitrary units)
(*a*)	Original solution (ethyl chlorophyllide in methyl alcohol, 1 5 × 10⁻⁴ m /l.)	100
(*b*)	Oxidized solution (same with 0·4 mgm. ferric chloride in 50 c.c.)	33
(*c*)	Recovered solution (solution *b* to which 5 mgm ferrous chloride were added immediately after reaction with ferric chloride)	96

(2) The reduction has to be carried out almost immediately (that is, not later than a few minutes) after the oxidation in order to give a complete recovery. This shows that the first oxidation product is unstable, and slowly reacts further (with the ferric chloride or possibly with dissolved oxygen). If the reduction is carried out, for example, 30 minutes after the oxidation, the green colour reappears, but the extinction curve of the reduced solution is situated somewhere between the curves *A* and *B* in Fig. 1. The fluorescence is also only partially restored. The oxidation product is especially unstable to light: a few seconds of intense illumination (by violet or blue light, but *not* by red light) suffice to destroy it, and no trace of recovery can be observed by adding ferrous chloride to the yellow solution after such illumination.

(3) By illuminating a methyl alcoholic solution of ethyl chlorophyllide, containing ferric chloride alone or, better, ferric chloride together with some ferrous chloride, by *red* light, a bleaching of the solution occurs, which is reversed as soon as the illumination ceases. The amount of the bleaching observed (that is, the decrease in the extinction coefficient for red light) was of the order of 1 per cent. (Extinction changes of this order of magnitude can be measured exactly by an optical compensation

arrangement described previously[1].) The stationary decrease in the concentration of the absorbing chlorophyll molecules during the illumination is proportional to the light intensity, and (roughly) inversely proportional to the concentration of ferrous chloride. It increases at first with increasing concentration of ferric chloride and then becomes independent of it—showing that under these conditions each excited chlorophyll molecule reacts with Fe^{III}. All these results agree with the assumption that the influence of light consists in shifting the equilibrium (I) to the right, that is, in speeding up the oxidation.

(4) These experiments show that ethyl chlorophyllide is *reversibly* oxidized by ferric chloride (that is, probably by Fe^{3}+-ions) to some unstable intermediary product from which it can be recovered by reduction with ferrous chloride (that is, probably by Fe^{2}+-ions), and that the *oxidation is greatly favoured by illumination*. These facts are obviously not without interest in connexion with the assimilation process, in which chlorophyll has to act as a catalyst for the reduction of carbon dioxide by light.

We wish to express our sincere thanks to Prof. F. G. Donnan for his kind interest in this work.

Note added in proof.

The formation of ferrous ions in the reaction between ethyl chlorophyllide and FeCl$_3$ can be proved directly by means of a spot test reaction with αα′ dipyrridyl. It has further been observed that the yellow solution of chlorophyllide, oxidized by FeCl$_3$, changes to a green colour by addition of various electrolytes, for example, NaCl, CaCl$_2$.

Translocation of Solutes in Plants

In my experiments on the eradication of *Dichapetalum cymosum* (Hook) Engl., one of the most toxic plants of the Transvaal, I was led to the following technique for introducing copper into the stem of the plant. The stem and branches of the plant are entirely underground and only the leaves emerge above the soil. The stem may be up to 100 ft. long. For the purpose of eradication, the stem is freed from the surrounding soil to a depth of about 9 in. and then ringbarked on a length of 2 in. for a 1 in. stem. Around this ringbarked region a mixture of the following substances is packed: calcium chloride, copper sulphate and soil in the proportion 2 : 1 : 2. The hole is then filled up again with soil. The circulation of the copper is very rapid; within twenty-four hours, leaves 15 ft. distant from the main stem are practically dead or dying. The downward movement is much slower; it takes eighteen days to kill 104 inches of the stem. The movement of the copper was followed with the help of potassium ferrocyanide, and it was noticed that the translocation takes place essentially in the phloem, although in the ringbarked region it is first taken up by the xylem. Only after about eight days does the xylem show copper in the same degree as the phloem does after twenty-four hours.

In my laboratory experiments, I used the following method. A ringbarked young twig was pushed down the stem of a glass funnel so that it emerged about 1 cm. at the lower end. This part was dipped into water. The ringbarked region was so arranged that it was situated in the conical part of the funnel. This region was then covered with a mixture of calcium chloride, copper sulphate and soil all finely powdered and mixed. The soil is necessary to prevent the formation of a hard cake; it seems also to induce rapid absorption, for without it the transport of copper is much slower. Results are obtained after twenty-four hours. The translocation in cut twigs is, however, far slower than in branches attached to the main stem, where a transpiration stream passes through them.

I have also tested the method on two species of *Acacia*, on *Burkea Africana* and *Ochna pulchra* ringbarked near the crown; in all cases I obtained a rapid movement of copper into the leaves.

These experiments were carried out with the sole object of finding a suitable method for eradication. The method has given very satisfactory results with *Dichapetalum cymosum*. The technique could, however, also be used for the study of the translocation of solutes as such. Instead of a toxic substance, sugars, nitrogen compounds, phosphates, etc., could be added to the mixture of calcium chloride and soil, and the different regions of the branch then could be analysed to establish the main path of translocation. Even if the calcium chloride reacts with some of the substances to be used (as it does with copper sulphate) the experiment will not be disturbed.

Differentiation of Varieties of Eucalypts by their Essential Oils

In continuation of our investigations into the occurrence of varieties of well-known species of eucalypts, *E. dives* and *E. radiata* (*E. numerosa*), *E. australiana*, etc., as determined by chemical analyses of the essential oils, we have made an interesting observation with *E. radiata* variety "A" which is considered worthy of early mention.

The occurrence of a number of varieties of *E. radiata* (*E. numerosa*) was investigated in 1930[1]. Young trees of the type and its varieties were raised from seed and the essential oils afterwards examined. These were found to be quite constant, with the exception of one tree of variety "A" which threw out two stems, each about 20 ft. in height, from the one root system. The leaves and terminal branchlets of each stem were examined separately and, to our surprise, they yielded different essential oils, one giving an oil indicative of variety "A" whilst the other was almost identical with what we prefer to regard as the type species. We are unacquainted with any record of a similar observation.

This observation provides additional evidence in support of our previous contention that the theory of the constancy of species, based upon the chemical composition of the essential oils, does not hold in every instance.

Full details of this investigation will be published in the *Journal and Proceedings of the Royal Society of New South Wales* for 1936.

Colour in the Dogfish, *Scyllium canicula*

SINCE the completion of a paper on colour change in the dogfish[1], two points of interest have arisen. The first concerns the colour cells and their natural responses in the young fish, and the second one concerns melanophore control in the various members of the group Elasmobranchii.

The colour cells of a young dogfish (*S. canicula*) hatched in the Zoology Department at Liverpool were investigated, and observations made on the natural responses of the melanophores. There proved to be four types of colour cells, only three of which have been described from the adult[1]. The natural melanophore responses to illuminated dark and light backgrounds were the same as in the adult fish[1].

In the newly hatched fish, focusing from the lower skin levels to the surface on the pectoral fin, there appear in order very conspicuous deep yellow cells capable of completely rounding off and of expansion to a stellate condition, greyish brown cells never seen in the contracted state but always with blunt irregular branches, light brown melanophores and finally, dark superficial melanophores. The yellow cells are numerous and very conspicuous, whereas in the adult they are very few and frequently cannot be found at all. The greyish brown type of cell has not previously been described from either the young[2] or adult[1] fish. The pigment from both these latter cells was dissolved out in alcohol. The two types of melanophore are exactly similar to those described from the adult fish[1].

Although on some occasions no melanophore response could be obtained, as a rule on an illuminated white background and in complete darkness the melanophores contracted, while on an illuminated black background they expanded. The melanophore response to illuminated dark and light backgrounds is, therefore, the same as in the adult[1], and the same as in the young[3] and adult[4] of *Mustelus*. The response to complete darkness is not known for the adult *Scyllium* or for the young or adult of *Mustelus*. The changes of the yellow cells and of the greyish brown cells have not been studied and the ultimate fate of the latter is not known. Unfortunately, the fish died.

The observations recently made by Parker on the colour change mechanism of *Raja erinacea*[5] and *Squalus acanthias*[6] direct attention afresh to the possibility of a lack of uniformity in the mechanism of colour control among the Elasmobranchii.

In *all* Elasmobranchs so far investigated[1,7,8] it is established that the normal dark background reaction (dark skin, expanded melanophores) is due to the activity of neuro-intermediate lobe of the pituitary. Where more detailed information is available, it is clear that the neuro-intermediate lobe exerts its influence by means of a blood-circulated hormone[1,9].

Regarding the mechanism of the natural light background reaction (contracted melanophores), however, there is no uniformity of opinion. In *Mustelus canis*, Parker and Porter[10] and Parker[11] have described and figured paling effects in dark fins as a result of faradic stimulus and of cuts made transverse to the fin rays. These effects have been interpreted by them as showing that the natural paling response in this fish is due to direct nervous action on the melanophores. On the other hand, cuts made by me[12] in the fin of a dark *Scyllium canicula* failed to give any paling effects, and severance of selected nerves by Young[13] in *Scyllium* sp. and by Wykes[14] in *Scyllium canicula*, *Raia brachyura* and *Raia maculata* did not influence the melanophore condition or, in the latter cases[14], the melanophore response in the area supplied by these nerves. Further, electrical stimulation of nerves[14] in *Raia brachyura*, *Rhina squatina* and *Scyllium catulus* did not result in any melanophore changes. From these negative results it has been concluded that there is no direct nervous control of melanophores in these fish.

In *Scyllium canicula*[1], *Raia maculata* and *Raia brachyura*[7] removal of the anterior lobe of the pituitary alone destroys the natural light background reaction, and from this it has been concluded that the natural paling response of these fish is in some way connected with the activity of the anterior lobe. The effect of removal of the anterior lobe alone on the light background response of *Mustelus canis* unfortunately has not been described.

The above facts have led me to suggest[15] that in the various members of Elasmobranchii there may be found different methods of melanophore control. This suggestion has now received considerable support from the observations of Parker himself that cuts made in the fins elicit no paling response whatsoever in *Raja erinacea*[5] and only a very uncertain response in *Squalus acanthias*[6].

The 'Specific Action' of Ultra-Short Wireless Waves

WE have received a letter from Prof. W. Szymanowski, of the Institute for Physiological Research at Moscow, in which he makes certain comments on our article on the above subject which recently appeared in NATURE[1]. We should like to be allowed to summarize these and to reply to them as briefly as possible.

(1) Prof. Szymanowski points out that his work with Dr. Hicks on the action of short waves on toxins and bacteria was begun, and a first note published[2] in 1930, before the corresponding work by Haase and Schliephake[3] (published 1931), so that our reference to the former work as confirmatory of the latter was likely to create a false impression in regard to priority. We admit the justice of this criticism, and tender our apologies to Prof. Szymanowski.

(2) In referring to two papers by Szymanowski and Hicks[4,5], dealing with the action of ultra-short waves on various bacteria, toxins, etc., we stated that in the second paper they withdrew their earlier results on toxin. Prof. Szymanowski takes exception to this statement, and makes it clear that no such withdrawal was intended. We accept his correction, and would merely remark that our impression was perhaps excusable in view of the general tone of the second paper, which, in contrast to the first, was mainly devoted to the presentation of negative evidence relating to the "specific effect", and included the sentence (p. 471): "The meagre character, however, of the action on diphtheria toxin and the delicacy of the conditions under which it may be

detected in any degree make it a phenomenon of relative insignificance in the interpretation of clinical or other studies of H.F. currents". Further, the authors state in conclusion (p. 472): "It is possible, however, to say from the work now reported, that at least there is no biologic action on the substances mentioned under the described conditions of exposure to ultra-high frequency field". We understand that Prof. Szymanowski did not mean to cast doubt on the reliability of the results in question, and are in full agreement with him that further investigation of these interesting effects is very desirable.

(3) Prof. Szymanowski further directs our attention to an interesting fact which had escaped our notice, namely, that in 1896 D'Arsonval and Charrin reported attenuation of diphtheria toxin by radiation of frequency 2×10^5 cycles per second, also without any dangerous temperature elevation. It is thus possible that such effects may be associated with high-frequency currents in general, rather than with ultra-short waves only.

(4) Prof. Szymanowski agrees with us that the overwhelming majority of the facts are consistent with a purely thermal explanation of the effects, and adduces some further evidence. For example, he has found[6], in a study of the lethal time of mice, an almost exact parallelism with the law of heating of electrolytes at these frequencies, and similar results, on *Drosophila*, were afterwards obtained by Malov[7]. Further, in work not yet published, he has shown that Pflomm and Liebesney's effect on the heartbeat of the frog, previously claimed as a clear case of a 'specific' effect, can be almost exactly reproduced by a very slow temperature elevation. We may mention that Hill and Taylor[8] have also shown that this effect is thermal in origin.

Prof. Szymanowski concludes by remarking that in spite of the meagreness of the positive evidence at the present time, it seems worth while to continue to look for it "by impartial and well controlled investigations". With this we entirely concur. The primary purpose of our article was to direct attention to the fact that scarcely any of the experimental work on which belief in specific effects has been based has satisfied both these conditions.

The Half-Drill Strip System Agricultural Experiments

"STUDENT'S" letter in NATURE of December 5 shows that he has overlooked the purpose of the paper he criticizes, although it was set out in the first sentence of the summary as follows:

"This enquiry was carried out to test the truth of the opinion expressed by 'Student' that randomization achieves its object 'usually at the expense of increasing the variability when compared with balanced arrangements', and that one of the means available to experimenters of reducing the error is by adopting 'a regular balanced arrangement'."

The quotations in this sentence are from "Student's" paper "Co-operation in Large-Scale Experiments", read before the Royal Statistical Society.

"Student" does not deny that the arrangement examined, and found to be extremely misleading, is, in fact, "a regular balanced arrangement". He even tells us that the method of calculating the error was that formerly used for half-drill strip experiments; though following his, "Student's", criticisms in 1923, "it has been customary" to use other methods of calculation for estimating the error.

It is not noticed, apparently, by "Student" that Dr. Barbacki and I criticize systematic arrangements in general on the ground that "the experimenter has an arbitrary choice between several widely different estimates". The two we show to be misleading correspond with the two random arrangements which we also test.

"Student" writes: "Had Prof. Fisher and Dr. Barbacki calculated the error on that basis" [as now advocated by "Student"] "they would have found a standard error of 2·37 per cent". This, then, it appears, is the standard error which "Student" thinks is appropriate for the systematic design discussed; yet we find that, on the same land, a random arrangement gives a standard error of less than 0·7 per cent. If "Student's" estimate is right, the randomized experiment is worth as much as the average of eleven such systematic experiments. This is, of course, a different ground of criticism from that on which I have habitually advocated randomization, for I cannot think that "Student's" new estimate is less arbitrary than the others. However, on his own result, what becomes of the claim that randomization tends to *increase* the error, or that experimenters can usefully try to diminish it by adopting regular balanced arrangements?

Hypoglycæmic Action of Histone Insulinate

BY mixing a solution of thymus histone with another of crystalline insulin, at pH 7–7·2, a precipitate is produced containing most of the insulin previously present in solution.

When administered to normal or pancreatectomized dogs, the histone insulinate gives a more prolonged hypoglycæmia than the pure crystalline insulin. The level and duration of this hypoglycæmia are practically identical with that obtained by injection of the same amount of protamine (clupein) insulinate, prepared also from crystalline insulin[1].

As this crystalline insulin contains zinc, it is not improbable that this metal has a favourable influence in the prolongation of the hypoglycæmia, specially in view of the experiments of Fisher and Scott[2].

The detailed account of this work will be published in full shortly.

Latent Heat of Evaporation of Liquid Helium

EARLY last year[1], Prof. E. F. Burton gave the results obtained by Messrs. Wilhelm and co-workers for the viscosity of liquid helium at three temperatures, attention being directed to the marked change as HeI is transformed into HeII.

The data, however, possess a further interest. In 1934, I showed that the molar latent heat of evaporation, L, can be calculated, with the aid of an equation similar to the Clausius-Clapeyron equation, from viscosity data at temperatures near the boiling point[2]. The equation is:

$$L = 9{\cdot}2\,R\,\frac{T_1T_2}{T_2 - T_1}\log_{10}\eta_1/\eta_2,$$

where R is the gas constant (1·985) and η_1, η_2 are the viscosities at the absolute temperatures T_1 and T_2.

Taking Burton's values, namely, $\eta_1 = 27 \times 10^{-6}$ at 2·3° K. and $\eta_2 = 11 \times 10^{-5}$ at 4·2° K., we find:

$$L = 36{\cdot}2.$$

If now we calculate L with the aid of the Clausius-Clapeyron equation using the data of Onnes, as given by Mellor in his "Comprehensive Treatise, etc.", namely, $p_1 = 760$ mm. at $-268{\cdot}71°$ C. and $p_2 = 565$ mm. at $-269{\cdot}03°$ C., we find,

$$L = 31{\cdot}3.$$

As this latter temperature range is slightly higher than the former, a somewhat smaller value for L is to be expected than in the first calculation. Bearing this in mind, and remembering also the extreme experimental difficulty in carrying out measurements with liquid helium, the close agreement between the two values of L is remarkable.

Points from Foregoing Letters

THE isotopic weights and 'packing fractions' for atoms of silicon (mass 28), phosphorus (31), sulphur (32) and chlorine (35 and 37) have been obtained by Dr. F. W. Aston with his 'second-order focusing' mass-spectrograph, by comparing doublets (atoms and groups of atoms having the same mass/charge ratio). Dr. Aston directs attention to an unexplained discrepancy between his results in the case of the O,CH_4 doublet and those of Bainbridge and Jordan.

A curve showing the absorption, in different thicknesses of boron, of the neutrons which produce gamma-ray activity in silver, is submitted by E. H. S. Burhop, R. D. Hill and A. A. Townsend. This curve indicates the presence of two components (with absorption coefficients of 8·1 and 0·24 gm.$^{-1}$ cm.^{2} respectively) and differs from the curves obtained from the absorption of neutrons which excite the 22- and 138-second activities in silver. The authors suggest that the nucleus may possess two systems of energy levels, corresponding to the emission of electrons and of gamma radiation respectively.

By irradiating silver with neutrons, first directly and then through a paraffin screen, Prof. G. Guében finds that three radioactive substances of half-life 50, 30 and 150 seconds, approximately, are produced. Apparently the first, which may be rhodium of mass 104, is produced by fast neutrons, the second by slow neutrons and the third by both fast and slow neutrons. Previous investigators have reported activities of 22, 26, 40, 138 and 154 seconds.

A simplified procedure for determining accurately the boiling point of a liquid (by the comparative method of Świętosławski) is described by Dr. M. Wojciechowski. If the pressure cannot be adjusted exactly to one atmosphere, a second pair of observations is made at a pressure only slightly different, so that the variation of the boiling point with respect to pressure can be assumed to be linear, and the necessary correction can then be made.

Depolarization factors of 0·10 and 0·17 have been obtained for the 3019·0 and 1343·9 Raman lines respectively in ethylene gas by S. Bhagavantam. This high degree of polarization is in accord with the origin of these lines. In the Raman spectrum of this gas, besides the intense lines, two weak lines which do not correspond to fundamentals but which were obtained by Bonner in the liquid have also been recorded.

M. Nicolet directs attention to the fact that from the numerous values recently proposed for the heat of dissociation of carbon monoxide, only the value $D(CO) = 9{\cdot}1$ e.v. is in good agreement with theoretical and observational knowledge of the composition of the atmospheres of late-type stars.

The hydrogenation-reduction of vitamin B_1 by platinum-black and by hydrosulphite is described by F. Lipmann. The author formulates the reaction on the assumption that the reduction takes place at the double bond closest to the nitrogen atom with four valency bonds.

That chlorophyll (ethyl chlorophyllide) is reversibly oxidized by ferric chloride with change in colour to greenish-yellow and quenching of fluorescence is shown by experiments carried out by Drs. E. Rabinowitch and J. Weiss. They find that the oxidation is greatly favoured by illumination, which is important in view of the part played by chlorophyll in photosynthesis.

The behaviour of the coloured cells in a young dog-fish, under illumination, is described by H. Waring, who finds four types of cells as against three types described in the adult fish. The author considers that in some fishes (sharks, rays, etc.) there is no direct control of the colour cells but that the 'paling' effect is in some way connected with the activity of the anterior lobe of the pituitary gland.

ERRATUM. In the second paragraph under this heading in NATURE of December 5, p. 976, for "From the interchangeability of lactic dehydrogenase from heart muscle with alcohol dehydrogenase . . ." read "From the interchangeability of lactic co-dehydrogenase from heart muscle with alcohol co-dehydrogenase from yeast . . ."

Research Items

Maternal Mortality and Malnutrition

THE causes of maternal mortality are many. Sepsis still occurs, though it is subdued, and is now low compared with "other causes", among which malnutrition appears to be important. This is the conclusion that emerges from recent investigations which are described in an article by Lady (Rhys) Williams in the October number of *Public Health*. The practical work described was begun in the Rhondda Valley, a distressed area, on January 1, 1934. In spite of increased ante-natal care and medical supervision, the puerperal death-rate there rose to 11·29 per 1,000 total births. In 1935, expectant and nursing mothers were provided with extra foodstuffs, tinned and bottled but protective, and one pint of milk a day, with the result that not a single mother, who had received the extra food, died. The feeding scheme was extended to include five adjoining towns of a similar type. Up to June 30, 1936, the puerperal rate had fallen to 5·46 in the Rhondda, and 3·75 in the new areas, as compared with the previous eight-year averages of 7·72 and 6·65, respectively; and the puerperal rate fell much more than the sepsis rate. Numerous graphs are reproduced which show a striking correspondence between the puerperal and the infantile death-rates when the latter relate to the preceding year. The divergence of the rates for the same year and their correspondence for successive years is explicable in terms of nutrition, and it is pointed out that these rates would have been affected simultaneously had climate or epidemics been the cause. Stronger evidence that malnutrition is an important cause of maternal and neo-natal mortality is afforded by the much higher average levels of the death-rate in distressed, as compared with prosperous, areas; and it is shown that the differences cannot be ascribed to climate or, to any extent, to bad housing (see also NATURE, 137, 529; 1936).

Tripolje Settlement in Kiev Province

SOVIET archæologists of the Marr Academy of Material Culture, excavating near the village of Khalepye in the province of Kiev, it is reported by the Soviet Union Year Book Press Service, have brought to light a settlement belonging to the Tripolje culture. The settlement was circular in plan, enclosed by a single row of houses, with doors opening on the enclosed space, the whole resembling a fort, into which the domestic animals were driven at night for protection. The houses were built of clay, and were about twenty metres long. The baked clay of the floors, and remains of stoves, walls and fences were found in an excellent state of preservation. The stoves and walls in some of the houses had been coloured with red ochre. The chief occupations of the inhabitants of the settlement were agriculture and cattle-breeding; but there is evidence that hunting had been an auxiliary means of livelihood. Many stone grinders and agricultural implements made of horn were found inside the houses. One hundred earthenware utensils ranged in size from very small receptacles of not more than two centimetres high to vessels seventy centimetres high. Thirty statuettes were found, some of which are unique. They give an idea of the dress of both men and women of the settlement. The women wore their hair loose, but tied in a knot at the ends, while an indispensable article of their attire was a girdle, the ends of which hung down at the side. The men are shown as wearing a garment draped across the shoulder. The excavations are to be continued next season.

Visual Acuity and Speed of Vision in Road Lighting

IN observing objects on artificially illuminated highways the first requirement is to perceive the presence of the object. This is rendered possible by the contrast between the object and the road surface. The nature of the contrast and the sensibility of the eye are the determining factors. When the object has been perceived, it is necessary to see its exact form and estimate its distance. This is governed by the visual acuity of the eye. It is customary to take the angle of vision at which two parallel lines are still just perceptible as separate entities. It is better to take the reciprocal of this angle (expressed in minutes), so that the larger number gives the greater visual acuity. Another method is to give the distance at which a circle with a diameter of 1 cm. and a square with a diagonal of 1 cm. can still just be differentiated. In addition to visual acuity, the speed of vision is also an important factor. In the *Philips Technical Review* (Eindhoven) of July, the relationship is investigated, by P. J. Bouma, between the visual acuity and the brightness levels of the object and the background. The difference also between the type of illumination and distance of observer from object is examined. Close investigation shows that all monochromatic colours, with the exception of blue and violet, give a greater visual acuity than white light. The low visual acuity for blue light is partly due to the fact that the eye is myopic for this short wave-length. With technical sources of light, the visual acuity is considerably greater with sodium and mercury light than with ordinary glow lamp and neon light. The author investigates the speed of vision for various types of light. For stationary objects, mercury and sodium lamps are better than glow lamps and neon light; but for moving objects sodium light is the best, then glow lamps and finally mercury light.

Sheep and Wool Production in North-Eastern Asia

THE total sheep population of China, Inner Mongolia and Manchukuo is round about 30,000,000, mostly run under nomadic conditions and carrying a low wool crop averaging only about 2·6 lb. a head. I. Clunies Ross points out (Pamphlet No. 65, Council for Sci. Ind. Research, Australia: Melbourne, 1936) that improved wool production by crossing between native and merino sheep is difficult because of climatic conditions and the effect particularly of the severe winter upon pastures, and would entail housing and hand-feeding during six months of the year. In Japan, sheep-rearing is not likely to become a major industry, but the movement of the Japanese and Chinese markets from cotton and silk to woollen materials indicates a prospect of further demand for wool, and since both nations are developing their own woollen factories, the demand will be of direct benefit to the export from Australia of raw wool, from which the imported tops are manufactured.

Prosobranchs of the North Sea and Baltic

DR. W. E. ANKEL has contributed an excellent monograph on the gastropods ("Die Tierwelt der Nord- und Ostsee" (Lief. 29, Teil 9,b, "Prosobranchia", von W. E. Ankel. Pp. 240. Leipzig: Akademische Verlagsgesellschaft m.b.H., 1936). Although it deals only (except in a few cases) with the species occurring in the North Sea and Baltic, there are so many of these which are common on all the coasts of Britain that it is practically a text-book of the prosobranchs of our seas, and the general matter applies to all. The author has himself worked specially on the reproduction and reproductive organs of these molluscs, but the clear original drawings scattered about the work show that he is a true naturalist in every sense of the word. Many of these figures are of the live animals, showing them crawling, burrowing, feeding, and are of distinction and quality. Besides bringing together a large amount of work by other authors showing a thoroughly up-to-date knowledge of the subject, this monograph contains much original matter. It is refreshing to find here so much that is really new. The life histories of most of our common prosobranchs are now known, and we have a fair idea of their egg-laying habits and development, but these descriptions are scattered far and wide. This is the first time that an attempt has been made to bring them together, and we gradually come nearer to the ideal work in which the description of every species shall be accompanied by notes on its life-history, and not only adult characters shall be used in classification, but also those of the embryonic and larval forms.

Japanese Diatoms

DR. H. AIKAWA has contributed an extensive paper "On the Diatom Communities in the Waters Surrounding Japan" in vol. 8, No. 1 of the Records of Oceanographical Works in Japan compiled by the Committee of Pacific Oceanography of the National Research Council of Japan. All plankton samples collected by the research ships of the prefectural fisheries experimental stations along the coast of Japan are submitted to the Imperial Fisheries Experimental Station, Tokyo, and the author has studied these in detail both quantitatively and qualitatively. The number of individuals of different species is counted in a sample by Hensen's method, and the respective percentages of animal and plant plankton worked out. The work is mainly concerned, however, with diatoms, and diatom communities are described from the waters around the West Aleutian Islands, Okhotsk Sea, the Tôhoku region, Tokyo Bay, Sagami Bay, Suruga Bay, the southern Pacific coast, the tropical regions and in the Japan Sea with Wakasa Bay and Tyôsen Strait. Both cold and warm currents flow around Japan. Enormous mass-production is found in cold waters, the warm water regions being richer in species. Seasonal succession is very noticeable in the neritic regions whilst the oceanic plankton is remarkably uniform. A list of forty of the principal diatom species shows many that are common in British waters.

Spiders of Lahore

A COMPREHENSIVE paper on the spiders of Lahore, by Mr. Sukh Dyal, has been issued (*Bull. Dept. Zoo.*, Punjab University, 1, 119–252). This work forms the fourth of a series entitled "Fauna of Lahore", published by the Punjab University. Altogether, 121 species are enumerated and are comprised in 60 genera and 20 families: of these, 46 species were previously undescribed. The majority of the spiders of the district appear to be web-spinners of arboreal habits, and among them are instanced several remarkable examples of protective coloration. The paper is provided with keys to the families, genera and species dealt with, and the text is illustrated with a number of well-executed plates showing diagnostic structural characters. At the end of the text, a rather extensive glossary of the terms employed is given, together with a list of relevant papers and memoirs.

Origin of Rice

MUCH progress is now being made in connexion with the cytology and genetics of rice. The chromosome number is $2n = 24$ in all varieties of *Oryza sativa* examined, although haploids with 12 chromosomes frequently occur. Dr. H. K. Nandi has brought forward (*J. Genetics*, 33, No. 2) results of much interest to show that the genus *Oryza* is a secondary polyploid derived from a previous basic number of 5, and Mr. S. Ramanujam has found that the related *Zizania aquatica* has $2n = 30$ and is therefore probably a hexaploid based on 5. In the pollen mother cells of rice varieties Dr. Nandi finds two pairs of satellited chromosomes of unequal length attached to the nucleolus, and very clear secondary pairing of the chromosomes in the metaphase of both meiotic divisions. The maximum pairing gives three groups of two and two groups of three bivalents, thus indicating that 5 was the primary chromosome number in *Oryza*. Haploids also occasionally show two bivalents. It thus appears that the genus *Oryza* originated as an allotetraploid through hybridization between two different ancestral species having $2n = 10$ chromosomes. Due to meiotic irregularities in the hybrid, two chromosomes were probably duplicated, and subsequent chromosome doubling produced a stable type with $2n = 24$. The conclusion is reached that on the basis of present evidence it cannot be determined whether the cultivation of rice began in China, India or Africa.

Heat-Treatment for Wood-Decaying Fungi

A SHORT paper by Mr. H. B. S. Montgomery (*Trans. Brit. Mycol. Soc.*, 20, pts. 3 and 4, Nov. 1936) gives the results of some experiments upon the lethal temperatures for a number of common wood-decaying fungi. Four species of the genus *Lenzites*, *Merulius lacrymans* (dry-rot fungus), *Poria vaporaria*, *Pholiota adiposa*, *Polyporus hispidus*, *Schizophyllum commune*, *Fomes fraxineus* and *Lentinus lepideus* have been studied. Temperatures which destroy each species are set forth in tabular form, and *Lenzites lepideus*, the most resistant of the fungi tested, was killed by electric motors. In this way it is possible to direct the beam of X-rays at will, either through the applicator towards the patient, or into an absorbing lead saddle, six inches thick, suspended immediately above the tube. Thus, the portion of the X-ray tube within the treatment room is both shock-proof and ray-proof.

As the X-ray tube is fixed, the floor of the treatment room has been made movable, so that the position of the patient relative to the tube may be adjusted as desired.

THE GENERATORS

The generating equipment comprises two generators, one designed to give a positive potential of 600,000 volts, and the other a negative potential of the same value (Fig. 2). The current for each generator is fed from the 400 volt A.C. mains into a transformer from which a current at 150,000 volts can be drawn. By means of a modified Greinacher circuit, embodying columns of continuously-evacuated thermionic valves and oil-immersed condensers, a rectified current at a constant potential of 600,000 volts may be obtained from each generator. Thus by using both generators, a constant potential of more than one million volts may be applied to the X-ray tube. At this voltage, the tube is designed to carry a current of five milliamperes.

The X-ray tube and its generating equipment is the culmination of the remarkable series of X-ray installations designed and manufactured during the past few years by the Metropolitan Vickers Electrical Co., Ltd., of Trafford Park, Manchester. The company is to be congratulated on its fine achievement.

The Treasurer and Governors of St. Bartholomew's Hospital, also, should be congratulated on the vision and energy they have displayed in their endeavour to further the conquest of a dread disease. We wish the new department all success in its work.

Illumination Research at the Science Museum

THE special Exhibition on Electric Illumination being held at the Science Museum (see NATURE of December 19, p. 1046) contains a number of research exhibits of considerable interest.

One item from which valuable results may be obtained has been contributed by the National Physical Laboratory and has been designed under the supervision of Dr. J. W. T. Walsh. Two light sources, one a tungsten filament lamp and the other equivalent to the mercury discharge lamp, may be adjusted by the observer until equal brightness appears to be obtained by means of a photometer head. When this has been done, the observer records his observation automatically on a roll of paper, thereby contributing towards the accumulation of mass statistics on popular conceptions of heterochromatic photometry. Practically all observations on this subject have been done hitherto by trained observers. It will be interesting to check whether the untrained observer, some 250,000 of whom will probably visit the exhibition, has substantially the same outlook on the question of equal brightness of differently coloured light sources. A rough check with a small number of completely untrained observers at the National Physical Laboratory revealed considerable disparities compared even with the observations of the less-experienced trained observers. The value of a check test to reveal the disparity range in the visual experiences of the general public may be considerable.

Another experimental device with the object of obtaining mass statistics has been installed by the E.L.M.A. Lighting Service Bureau. Variations in the foot-candle intensity chosen by members of the public for comfort in reading are recorded by a ticket issuing machine which, in addition to delivering a ticket showing the value chosen by the operator, records statistically the sum of its operations. Although 5 foot-candles is an average value of illumination experienced in living rooms, it has been found as a result of 20,000 observations that 70 foot-candles is much nearer the desired value for comfort. Further statistics will be obtained at the Exhibition.

A number of other items in the Exhibition illustrate contemporary research without contributing towards it. One most interesting exhibit projects the arc from a mercury discharge lamp on to a translucent screen, and by means of a stroboscopic disk shows that while the cathode discharge emanates from a hot spot on the cathode, the anode discharge takes place from the surface of the electrode presenting the shortest discharge path to the arc. If both these discharges were to take place from the same spot, disintegration of the electrodes would ensue and the lamp life would be uneconomically curtailed. This device, which has been used extensively by research workers to obtain a proper understanding of the processes involved in sustaining the arc discharge in a hot cathode discharge lamp, is now demonstrated to the public.

The phenomenon of luminescence, discovered by Crookes in 1879 and now applied to electric discharge lamps, is demonstrated by a number of cabinets in which only invisible ultra-violet radiation is allowed to fall on luminescent specimens. The first cabinet shows naturally luminescent minerals. The second shows stages in the preparation of a synthetic luminescent material. Pure zinc sulphide is not luminescent, and does not become so with the addition of an impurity. When, however, the mixture is fired, the resultant product is strongly luminescent. Two further cabinets show the response of some materials to long-wave ultra-violet radiation and others to short-wave ultra-violet, and the fact that a material responding to the one may be unresponsive to the other. A fifth cabinet shows the response of the rhodamines which, strangely enough, respond only in the pure form and then only when in either solid or liquid solution.

The water-cooled high-pressure hot cathode mercury discharge lamp is an example of what is at present a research exhibit, but may before long have important practical applications. The tube is of quartz surrounded by a condenser, and from examination of the spectrum of the discharge it is estimated that a temperature of about 8,000° C.—approximately that of the sun—is reached. The light source is 0·5 mm. diam. × 50 mm. long, the pressure 100–200 atmospheres and the power consumption 1,000 watts. An efficiency of 60–70 lumens per watt is obtained. While the life of these lamps is at present only about 100 hours, the red end of the spectrum of the discharge is about ten times as strong as that of an ordinary street-lighting mercury lamp. The colour rendering of the light obtained is thus far more akin to that obtainable by daylight. Even the commercial high-pressure quartz lamp, which will probably be marketed in a few months' time and which works at a pressure of about five atmospheres and a temperature of about 1,000° C., shows a substantial improvement in the red end of the spectrum. Spectrometer demonstrations of the light from these lamps compared with that from tungsten filament lamps are shown.

Universities of the British Empire

FIFTH QUINQUENNIAL CONGRESS

At the fourth Congress of the Universities of the British Empire in 1931, Sir Donald MacAlister observed that not merely for historical or statistical records, but also for the clear and cogent setting forth of current university problems, and for pertinent and practical suggestions for their solution, it had long been his practice to consult the reports of the Proceedings of these Congresses, and seldom in vain.

The Proceedings of the Fifth Congress, held on July 13–17, 1936 in Cambridge*, in no way fall below the standards established by its predecessors, and suggest that the analysing and Socratic methods of the world's earliest university are alive in the modern world's counterparts of the Academy of Athens. "They say. What say they ? Let them say," is the background of their work and effort—taking toll of the past, working for the present, planning for the future—a readiness to discard the unprofitable, to adapt means to ends and to envisage change.

The Prime Minister in his opening address took his stand on the plane of a lofty idealism which stressed the presence of the spirit of youth, of growth, of vigour, of expansion and of adventure in his own university and the hatred of standardization and mass production—common to all universities ; and pleaded for the production of poets like Wordsworth who might inspire Europe and the world with a sense of unity and freedom.

On other aspects of the problems confronting universities, Mr. Baldwin was no less insistent. Research workers should be freed from the trammels of too much teaching and relieved from financial anxiety. Communal life is by no means the least important part of the training obtained at universities—a view strongly expressed in the latest report of the University Grants Committee. Universities may have to specialize in certain subjects and arrange for an exchange of students in the event of their being unable to provide for complete instruction in any subject—the latter suggestion recently happily adopted by the Universities of Oxford and Cambridge.

It was appropriate that the Chancellor should be followed by the Vice-Chancellor, who discoursed on some problems which confront universities. He, too, referred to undue specialization and its dangers—making mention of the arrangement come to with the University of Oxford in respect of the School of Forestry. He had also much that was pertinent to say about training for citizenship—a subject to the discussion of which Sir Ernest Simon made a valuable contribution in his remarks on general, as an alternative to specialized, honours courses, matriculation standards (a question of vital concern to all educational institutions, schools as well as universities), pass degrees, intensive courses in honours subjects, research, libraries, need for wider exchange and health measures for students.

Following this address, the subject of the provision in Great Britain for post-graduate studies for British and overseas students was introduced by Lord Macmillan, who made an eloquent appeal for the establishment of an institute of legal research. The Vice-Chancellor of the University of London gave a lucid description of what is being done for post-graduate medical education by the British Post-graduate Medical School. Lord Rutherford explained what his department is doing at the Cavendish Laboratory, Cambridge ; and one of his colleagues, Prof. J. A. Ryle, told of the development of research in pure medicine at Cambridge. Lord Nuffield's recent munificent gift to Oxford will enable research to be conducted in other departments of the medical faculty.

The functions of universities in the training of teachers was introduced by Sir T. Percy Nunn. One of the more important and trenchant of his observations was that the universities through their technical departments of education should do more to foster education as a national function. Others spoke on the subject from the point of view of overseas institutions, while the Board of Education, through its chief inspector, suggested certain criticisms of university methods to which full consideration should be given. Among these is the isolation of the teacher's life which, as Prof. Frank Smith of Leeds said, must not constitute what is really a condition of imprisonment.

Dr. H. J. Cody, president of the University of Toronto, delivered an address on the relation of Canadian universities to national life, making particular mention of academic freedom, the importance of the great and inspiring teacher and of physical training.

Two subjects for discussion—careers for university students and physical education in the universities—were, as was appropriate, concerned with the well-being of those for whom university education is provided. Great Britain is happy in that it has not experienced as yet the effects of a surplus of failed aspirants for university degrees or even of 'failed matrics'. A career for the university graduate is not

Exploration of the Mississippi

The Times of December 30, 1836, quoting the *St. Louis Enquirer* of November 14, said: "The distinguished French astronomer and mathematician, Mr. J. N. Nicollet, now engaged in a tour of scientific observation through the different states and territories of the Union, has recently visited the northern regions of the United States, and succeeded in penetrating further into the interior, with a view of making the discovery of the true source of the great 'Father of Waters' than has even been before accomplished. Mr. Nicollet left Port Snelling, mouth of the St. Peter's, about three months since, and at great expense and trouble transported his splendid set of astronomical and other instruments through a country offering obstacles at every step, taking advantage of every opportunity to ascertain latitudes, longitudes, the magnetical variation and dip, the intensity of the force of gravity, geological and mineralogical examination, and indeed every other observation connected with the science, which might be considered useful, not only to himself and the various scientific and literary societies in Europe and the United States, to which he belongs, but to the whole scientific world. . . ."

"It is laid down and established by Mr. Nicollet that the true source of the 'Father of Waters' is to be found in five different rivers, an extension of the waters of which forms La Beasch Lake. Thus has the honour of this discovery so long contended for by many travellers and writers, been reserved for Mr. Nicollet, and we sincerely hope he may succeed (as no doubt he will) in the establishment of his superior claims to the distinction."

Dutrochet's Experiments in Vegetable Physiology

IN the *Athenæum* of December 31, 1836, under the heading "The Breathing of Vegetables" was a reference to the latest researches of the French physiologist and naturalist Rene-Joachim-Henri-Dutrochet (1776–1847). M. Dutrochet, said the *Athenæum*, has recently laid before the Paris Academy of Sciences some further information on his experiments on vegetable physiology. Having observed that the pneumatic organs in different parts of *Nymphæa lutea* contained an air in which there was less oxygen in proportion as these parts were distant from the leaves, it struck him, that the leaves were the sources whence these organs derived their oxygen, and that this oxygen was disposed of by the breathing of the plant, as in animals. After stating his observations at length, M. Dutrochet said: "The results of these experiments are, that the oxygen produced by the leaves under the influence of light is first poured into the pneumatic cavities: into these it is pressed by continued accumulation, and escapes to the outer surface by means of the tracheæ, the orifices of which are situated in the air, and on the leaves. Most of the aquatic plants have these orifices so contrived as not to be entirely closed when in contact with the water, but a few are without these mouths, and then the oxygen is crowded into the pneumatic canals of the footstalks, and from thence is pressed into the stem, which accounts for the enormous quantity of water contained in some of the aquatic plants". Dutrochet re-published the most important of his researches in his "Memoires pour Servir à l'histoire anatomique et physiologique des vegetaux et des animaux" in 1837.

Societies and Academies

Dublin

Royal Dublin Society, November 24, 1936.

H. H. DIXON: The convection of heat and materials in the stem of a tree. When heat is applied locally to the stem of a tree, it is conducted and conveyed both upwards and downwards. The convection is brought about by the movement of material. By means of suitably devised and controlled arrangements, the velocities and the times of these movements may be ascertained and recorded. Movements quite distinct from the movement of water upwards from the roots to the leaves have in this way been observed. They take place in winter, spring and autumn, as well as in summer. They may be found when the tree is bare of leaves and in the darkness of night. While the water from the soil moves upward in the wood, the bark is indicated as the channel for these movements.

J. H. J. POOLE: A new method of measuring the radioactivity of rocks. The powdered rock is heated in a carbon boat carrying a current of about 400–500 amperes in a water-cooled vacuum furnace. The gases evolved, including the radon from the radium present, are then pumped into a previously exhausted ionization chamber, where the number of alpha particles due to the radon and active deposit is counted by means of an amplifier of the Wynn Williams type and an oscillograph. The results so far obtained agree reasonably well with previous measurements made by other methods. An account was also given of some measurements of the radium content of specimens of basalt from the bottom of the Indian Ocean, made by the usual furnace method. The results are appreciably lower than those for surface specimens of basalt.

G. T. PYNE and J. J. RYAN: Investigations on a molecular constant for soured milks. An application to soured milk of the method previously described for the determination of the cryoscopic constant of fresh milk from measurements of its refractive index, chloride content, and soluble phosphate content.

Paris

Academy of Sciences, November 30 (*C.R.*, 203, 1105–1192).

EMILE BOREL: The problem of chances.

HENRI DOUVILLÉ: The shell of the Ostreidés, of the group of *Ostrea cochlear*, genus *Pycnodonta*, and the shell of the Rudists.

RAZIUDDIN SIDDIQI: The theory of non-linear partial differential equations.

J. FAVARD: The approximation of periodic functions by trigonometrical polynomials.

V. A. KOSTITZIN: The asymptotic solutions of biological differential equations.

EDMOND BRUN: Study of the friction of a solid moving in water. When an ebonite disk is rotated at a high velocity in water, there is a measurable temperature difference between the solid and the water; this difference is a function of the distance from the axis of rotation, and is proportional to the square of the velocity of rotation.

JEAN CHAZY: Certain laws of gravitation corrective of Newton's law.

HENRI CAMICHEL: The spectrum of Nova Lacertæ observed with the large telescope at Meudon. The results are in general agreement with what is known about novæ, but there are certain peculiarities. Nova Lacertæ differs from Nova Herculis: its light curve is of the rapid evolution type, its emission lines are wide and badly defined, and it shows lines of interstellar sodium.

BERNARD KWAL: The spatio-temporal fixing of positions and relations of uncertainty in quaternion quantic mechanics.

PHILIPPE TONGAS: A new empirical expression for the specific volume of super-heated steam.

DAVID RAISKY: A new musical string instrument, the bass violin. The instrument described has the range of a violoncello with dimensions approximating to those of a violin.

GEORGES FOURNIER: A geometrical theory of matter.

DOUCHAN AVSEC and MICHEL LUNTZ: Electroconvective vortices. In an electrostatic field, formed in oil between two plane parallel electrodes, cellular vortices of the Bénard type are formed. It is suggested that the existence of these electroconvective vortices may explain a large number of physical, meteorological, astrophysical and crystallographic phenomena.

AUGUSTIN BOUTARIC, LOUIS FERRÉ and MME. MADELEINE ROY: Spectro-photometric researches on the colour of wine.

TIEN KIU: Photographic plates sensitized with sodium salicylate. Treatment with sodium salicylate solutions increases both the contrast and sensibility in the visible spectrum. The action of this reagent is more complex than was at first supposed: the fluorescence theory is insufficient to cover the whole of the facts.

EMILE SEVIN: Zeeman's phenomenon.

ROBERT J. WALEN and MAURICE E. NAHMIAS: Research on the negative proton and some artificial radioactivities.

MARCEL PRETTRE: The laws governing the initial acceleration of slow combustion and delay in inflammation of mixtures of pentane, oxygen and nitrogen.

GABRIEL VALENSI: The mechanism of diffusion through protective oxides and the influence of pressure on the velocity of oxidation of nickel.

GEORGES CARPÉNI: The dissociation constants of reductinic acid and its product of oxidation by iodine. As might have been predicted from its constitution and chemical properties, reductinic acid is, from the point of view of electrometric titration, in every way analogous with reductone and with ascorbic acid. This also applies to its oxidation product with iodine.

MAX BOBTELSKY and MME. LJUBA BOBTELSKY-CHAJKIN: The influence of added catalysts on the catalytic decomposition of hydrogen peroxide in the presence of bichromate.

HUBERT FORESTIER and FRANÇOIS REDSLOB: Decomposition of cadmium ferrite. Study of the conditions under which cadmium ferrite acquires ferromagnetic properties: these properties are shown to be due to the ferric oxide in an unstable ferromagnetic form.

HENRI GUÉRIN: Combined action of hydrogen and heat on the arsenates of the alkaline earths.

SÉBASTIEN SABETAY: A method for the rapid diagnosis and approximate estimation of the primary alcohols, in the presence of secondary and tertiary alcohols, by the formation of trityl esters. The reagent proposed is triphenylchloromethane, which gives esters with primary alcohols of the type $(C_6H_5)_3COR$.

A. VILA: Application of distillation in a cathodic vacuum to the definition of pitches and bitumens.

PIERRE CHATELAIN: Study of parazoxyanisol in the solid, anisotropic liquid, and isotropic liquid states.

FERNAND JACQUET: The southern side of the Tindouf synclinal in the regions of northern Mauritania.

LOUIS DUBERTRET: The stratigraphy of the regions covered by the green rocks of north-west Syria.

MAURICE HOCQUETTE and LÉON ARSIGNY: The mode of formation, action and destiny of the prehaustorium of *Cuscuta epithymum*, var. *trifolii*.

RAYMOND HAMET: The botanical origin of the drugs known in Brazil under the name of 'catuaba'.

RENÉ COUTEAUX: The bacteroids of worms and their relations with sarcolysis.

JEAN JACQUES BOUNHIOL: The limits of decerebration of the larvæ of Lepidoptera compatible with nymphosis.

PIERRE NICOLLE: Researches on the role of the hormones in the physiological variations of the reticulocytary ratio in the rabbit.

GABRIEL GUIGNON: The influence of sunlight on the flight of the diurnal Lepidoptera.

ALBERT VANDEL: The mode of distribution of the sexes in *Trichoniscus* (*Spiloniscus*) *provisorius*. The heredity of monogeny.

A. H. ROFFO and A. E. ROFFO, jun.: Ionization of air by irradiated cholesterol. The irradiation of cholesterol by ultra-violet light is accompanied by ionization phenomena.
